THE ENCYCLOPÆDIA BRITANNICA

FOURTEENTH EDITION

VOLUME 16 MUSHROOM TO OZONIDES

MUSHROOM. The edible fungus of this name is known botanically as *Agaricus campestris* or *Psalliota campestris*. It grows in short grass in the temperate regions of all parts of the world. Many edible fungi depend upon minute and often obscure botanical characters for their determination, and may readily be confounded with worthless or poisonous species; but that is not the case with the common mushroom, for, although several other species of *Agaricus* somewhat closely approach it in form and colour, yet the true mushroom, if sound and freshly gathered may be distinguished from all other fungi with ease. It almost invariably grows in rich, open, breezy pastures, in places where the grass is kept short by the grazing of horses, herds and flocks. Although this plant is popularly termed the "meadow mushroom," it never as a rule grows in meadows. It never grows in wet boggy places, never in woods, or on or about stumps of trees. An exceptional specimen or an uncommon variety may sometimes be seen in the above-mentioned abnormal places, but the best, the true, and common variety of the table is the product of short, upland, wind-swept pastures. A true mushroom is never large in size; its cap very seldom exceeds 4, at most 5 in. in diameter. The large examples measuring from 6 to 9 or more in. across the cap belong to *Agaricus arvensis*, called from its large size and coarse texture the horse mushroom, which grows in meadows and damp shady places, and though generally wholesome is coarse and of inferior flavour. The mushroom usually grown in gardens or hot-beds, in cellars, sheds, etc., is a distinct species known as *Agaricus hortensis*. On being cut or broken the flesh of a true mushroom remains white or nearly so, the flesh of the coarser horse mushroom changes to buff or sometimes to dark brown. To summarize the characters of a true mushroom—it grows only in pastures; it is of small size, dry, and with unchangeable flesh; the cap has a frill; the gills are free from the stem; the spores brown-black or deep purple-black in colour, and the stem solid or slightly pithy. When all these characters are taken together no other mushroom-like fungus—nearly a thousand species grow in Britain—can be confounded with it.

The parts of a mushroom consist chiefly of stem and cap; the stem has a clothy ring round its middle, and the cap is furnished underneath with numerous radiating coloured gills, free from the stem. The cap is fleshy, firm and white within, never thin and watery; externally it is pale brown, dry, often slightly silky or

floccose, never viscid. The cuticle of a mushroom readily peels away from the thick flesh beneath. The cap has a narrow dependent margin or frill; this originates in the rupture of a delicate continuous wrapper, which in the infancy of the mushroom entirely wraps the young plant. The gills underneath the cap are at first white, then rose-coloured, finally brown-black. A point of great importance is to be noted in the attachment of the gills near the stem; the gills in the true mushroom are, however, usually more or less free from the stem, they never grow boldly against it or run down it; they may sometimes just touch the spot where the stem joins the bottom of the cap, but never more; there is usually a slight channel all round the top of the stem. When a mushroom is perfectly ripe and the gills are brown-black in colour, they throw down a thick dusty deposit of fine brown-black or purple-black spores; it is essential to note the colour. The stem is firm, slightly pithy up the middle, but never hollow; it bears a floccose ring near its middle; this originates by the rupture of the thin general wrapper of the infant plant.

Like all widely spread and much-cultivated plants, the edible mushroom has numerous varieties, and it differs in different places and under different modes of culture in much the same way as our kitchen-garden plants differ from the type they have been derived from, and from each other.

Many instances are on record of symptoms of poisoning, and even death, having followed the consumption of plants which have passed as true mushrooms; these cases have probably arisen from the examples consumed being in a state of decay, or from some mistake as to the species eaten. It should always be specially noted whether the fungi to be consumed are in a fresh and wholesome condition, otherwise they act as a poison in the same way as any other semi-putrid vegetable. Many instances are on record where mushroom-beds have been invaded by a growth of strange fungi and the true mushrooms have been ousted. When mushrooms are gathered for sale by persons unacquainted with the different species mistakes are of frequent occurrence. A very common spurious mushroom in markets is *A. velutinus*, a slender, ringless, hollow-stemmed, black-gilled fungus, common in gardens and about dung and stumps; it is about the size of a mushroom, but thinner in all its parts and far more brittle; it has a black hairy fringe hanging round the edge of the cap when fresh. Another spurious mushroom, and equally common in dealers' baskets, is *A. lacrymans*; this grows in the same positions as the last, and is somewhat fleshier and more like a true mushroom; it

has a hollow stem and a slight ring, the gills are black-brown mottled and generally studded with tear-like drops of moisture. In both these species the gills distinctly touch and grow on to the stem. Besides these there are numerous other black-gilled species which find a place in baskets—some species far too small to bear any resemblance to a mushroom, others large and deliquescent, generally belonging to the stump- and dung-borne genus *Coprinus*. The true mushroom itself is to a great extent a dung-borne species, therefore mushroom-beds are always liable to an invasion from other dung-borne forms.

Sometimes cases of poisoning follow the consumption of what have really appeared to gardeners to be true bed-mushrooms, and to country folks as small horse mushrooms. The case is made more complicated by the fact that these highly poisonous forms now and then appear upon mushroom-beds to the exclusion of the mushrooms. This dangerous counterfeit is *A. fastidiosus*, or sometimes *A. crustuliniformis*, a close ally if not indeed a mere variety of the first. A description of one will do for both, *A. fastidiosus* being a little the more slender of the two. Both have fleshy caps, whitish, moist and clammy to the touch; instead of a pleasant odour, they have a disagreeable one; the stems are ringless, or nearly so; and the gills, which are palish-clay-brown, distinctly touch and grow on to the solid or pithy stem. These two fungi usually grow in woods, but sometimes in hedges and in shady places in meadows, or even, as has been said, as invaders on mushroom-beds. The pale clay-coloured gills, offensive odour, and clammy or even viscid top are decisive characters. Besides the foregoing the difference in the nature of the attachment of the gills near the stem, the absence of a true ring, and of a pendent frill will be noted. The colour, with the exception of the gills, is not unlike that of the mushroom. In determining fungi no single character must be relied upon as conclusive, but all the characters must be taken together. Sometimes a beautiful, somewhat slender, fungus peculiar to stumps in woods is mistaken for the mushroom in *A. cervinus*; it has a tall, solid, white, ringless stem and somewhat thin brown cap, furnished underneath with beautiful rose-coloured gills, which are free from the stem as in the mushroom, and which never turn black. It is probably a poisonous plant, belonging, as it does, to a dangerous cohort. Many other species of *Agaricus* more or less resemble *A. campestris*, notably some of the plants found under the subgenera *Lepiota*, *Volvaria*, *Pholiota* and *Psalliota*; but when the characters are noted they may all with a little care be easily distinguished from each other. The better plan is to discard at once all fungi which have not been gathered from open pastures; by this act alone more than nine-tenths of worthless and poisonous species will be excluded.

In cases of poisoning by mushrooms immediate medical advice should be secured. The dangerous principle is a narcotic, and the symptoms are usually great nausea, drowsiness, stupor and pains in the joints. A good palliative is sweet oil; this will allay any corrosive irritation of the throat and stomach, and at the same time cause vomiting.

In Paris mushrooms are cultivated in enormous quantities in dark underground cellars at a depth of from 60 to 160 ft. from the surface. The stable manure is taken into the tortuous passages of these cellars and the spawn introduced from masses of dry dung where it occurs naturally. In France mushroom-growers do not use the compact blocks or bricks of spawn so familiar in England, but much smaller flakes or "leaves" of dry dung in which the spawn or mycelium can be seen. Less manure is used in these cellars than is generally seen in the mushroom-houses of England, and the surface of each bed is covered with about an inch of fine white stony soil. The beds are kept artificially moist by the application of water brought from the surface, and the different galleries bear crops in succession. As one is exhausted another is in full bearing, so that by a systematic arrangement a single proprietor will send to the surface from 300 lb. to 3,000 lb. of mushrooms per day. The passages sometimes extend over several miles, the beds sometimes occupying over 20 m., and, as there are many proprietors of cellars, the produce of mushrooms is very large. The mushrooms are not allowed to reach the fully expanded condition, but are gathered in a large button state, the whole growth of the mushroom

being removed and the hole left in the manure covered with fine earth; the beds remain in bearing for six or eight months. The equable temperature of these cellars and their freedom from draught is one cause of their great success and to this must be added the use of natural virgin spawn.

The fairy-ring mushroom or champignon, *Marasmius Oreades*, is more universally used in France and Italy than in England, although it is well known and frequently used both in a fresh and in a dry state in England. It is totally different in appearance from the pasture mushroom, and, like it, its characters are so distinct that there is hardly a possibility of making a mistake when its peculiarities are once comprehended. It has more than one advantage over the meadow mushroom in its extreme commonness, its profuse growth, the length of the season in which it may be gathered, the total absence of varietal forms, its adaptability for being dried and preserved for years, and its persistent delicious taste. It is by many esteemed as the best of all the edible fungi found in Great Britain. Like the mushroom, it grows in short open pastures and amongst the short grass of open roadsides.

The fairy-ring mushroom is about one-half the size of the pasture mushroom, and whitish-buff in every part, the gills always retaining this colour and never becoming salmon-coloured, brown or black. The stem is solid and corky, much more solid than the flesh of the cap, and perfectly smooth, never being furnished with the slightest trace of a ring. The buff gills are far apart, and in this they greatly differ from the somewhat crowded gills of the mushroom; the junction of the gills with the stem also differs in character from the similar junction in the mushroom. The mushroom is a semi-deliquescent fungus which rapidly falls into putridity in decay, whilst the champignon dries up into a leathery substance in the sun, but speedily revives and takes its original form again after the first shower. To this character the fungus owes its generic name (*Marasmius*) as well as one of its most valuable qualities for the table, for examples may be gathered from June to November, and if carefully dried may be hung on strings for culinary purposes and preserved without deterioration for several years; indeed, many persons assert that the rich flavour of these fungi increases with years. Champignons are highly esteemed for flavouring stews, soups and gravies.

A fungus which may carelessly be mistaken for the mushroom is *M. peronatus*, but this grows in woods amongst dead leaves, and has a hairy base to the stem and a somewhat acrid taste. Another is *M. urnus*; this also generally grows in woods, but the gills are not nearly so deep, they soon become brownish, the stem is downy, and the taste is acrid. *Agaricus dryophilus* has sometimes been gathered in mistake for the champignon, but this too grows in woods where the champignon never grows; it has a hollow instead of a solid stem, gills crowded together instead of far apart, and flesh very tender and brittle instead of tough. Another small and common species, *M. porreus*, is pervaded with a garlic flavour; a third species, *M. alliaceus*, is also strongly impregnated with the scent and taste of onions or garlic. Two species, *M. imprudicus* and *M. foetidus*, are in all stages of growth highly foetid. The curious little edible *Agaricus esculentus*, although placed under the subgenus *Collybia*, is allied by its structure to *Marasmius*. It is a small bitter species common in upland pastures and fir plantations early in the season. Although not gathered for the table in England, it is greatly prized in some parts of the Continent.

In the United States and Canada many hundred species of edible fungi occur, many of which are highly prized for their delicious flavour. In the moister districts, especially in the eastern States and Provinces, numerous choice species are found in abundance, including several of the best-known Old World mushrooms, as the meadow mushroom (*Psalliota campestris*), the fairy ring (*Marasmius Oreades*) and the chanterelle (*Cantharellus cibarius*). However, owing to the wide prevalence of the deadly amanita or death angel (*Amanita phalloides*), the fly mushroom (*A. muscaria*), and other dangerously poisonous species, extreme caution must be exercised in gathering native mushrooms for the table. Because of the frequency of fatal cases of mushroom poisoning, sometimes 30 a year in New York city and vicinity, wild mushrooms should never be eaten, even in the smallest

quantities, until their identification as wholesome species has been determined with absolute certainty. Poisoning by the deadly *amanita*, even when it is eaten in minute quantities, has been almost invariably fatal despite all medical treatment. Recently, however, an antiphallinic serum, prepared by the Pasteur Institute of Paris, has proved so effective as a remedy that the French government requires by law each *département* to keep a supply of it available for use by physicians.

There are, however, many wholesome wild species, of excellent quality and flavour, that are readily distinguishable from the noxious kinds. Among the easily recognized edible species are the shaggy mane (*Coprinus comatus*), the inky cap (*Coprinus atramentarius*), the oyster mushroom (*Pleurotus ostreatus*), the honey agaric (*Armillaria mellea*) and the parasol mushroom (*Lepiota procera*), regarded by many authorities as the best edible mushroom. Besides the foregoing all morels, coral fungi and puff balls, if used when fresh, are edible. See FUNGI; MOREL; PUFF BALL; TRUFFLE.

See W. G. Smith, *Mushrooms and Toadstools* (1879); W. Falconer, *Mushrooms; How to Grow Them* (1891, 1925); M. C. Cooke, *Edible and Poisonous Mushrooms* (1894); G. F. Atkinson, *Edible and Poisonous Mushrooms* (1903); N. L. Marshall, *The Mushroom Book* (1905, 1923); R. L. Castle, *Mushrooms* (1910); E. L. T. Cole, *Guide to the Mushrooms* (1914); W. B. McDougall, *Mushrooms* (1925); W. S. Thomas, *Field Book of Common Gilled Mushrooms* (1928).

MUSHROOMS, COOKERY OF. Edible mushrooms contain some nitrogenous food and about 90% water. Eaten with other foods they are of great service in the diet on account of their flavouring properties. It is dangerous to eat mushrooms which have been gathered by anyone who has not studied the different kinds.

Among the most familiar kinds are the common meadow mushroom (*Agaricus campestris*); button (immature) mushrooms employed chiefly for garnishing purposes and as an addition in high-class dishes; and truffles (underground fungi).

To prepare ordinary mushrooms for cooking, pick over and wipe with a flannel dipped in salt. Peel and remove stalks where necessary. The latter may be used for flavouring stews, soups, sauces, etc.

Mushrooms may be grilled (broiled) and served with maître d'hôtel or plain butter, etc.; baked in the oven under glass (or in a shallow dish); stewed in a casserole with other foods, e.g., Italian pastes, rice, or in a well-flavoured sauce; or, they may be used in stuffings for turkey, poultry and game; they are also employed for garnishes in making galantines, etc.

Stewed Mushrooms.—Place the mushrooms in a stewpan with 2 oz. of butter, salt, a squeeze of lemon juice and a blade of mace. When cooked, stir in a white liaison of flour and butter blended together. Stir well and serve either as an entrée, or on toast as a savoury. This dish may be varied by adding other ingredients and may be served as a cream by adding a sauce of cream and beaten-up eggs.

Fried Mushrooms.—These are frequently added as an addition to a mixed grill. Frying should be done in a frying pan and not in a deep pan of fat. It is best to use good margarine or butter.

Grilled Mushrooms.—Large mushrooms should be chosen for grilling. Grease the gridiron before cooking. Place flesh side uppermost on the gridiron.

Stuffed Mushrooms.—Good-sized mushrooms are needed for stuffing. Any well-flavoured forcemeat can be used though certain flavours blend better with mushrooms than others, e.g., game. To stuff, remove the stalks and pile the forcemeat in the centre of each mushroom. Squeeze lemon juice over and cover with buttered paper or place under glass. Bake in the oven for half an hour.

Mushroom Ketchup.—Sprinkle salt freely over large meadow mushrooms and leave them to stand for a few hours, then mash them in a mortar and set aside for 48 hours. Stir from time to time. Press through a colander and place in a pan. Boil up, skim carefully and simmer for an hour. Strain into a pan and leave until the next day. Then strain again leaving the sediment at the bottom of the basin and add one ounce of black peppercorns, a blade of mace, half an ounce of allspice, one quarter of an ounce of ginger and half an eggspoonful of grated lemon rind

to each quart of liquor. Boil up and reduce to half the quantity. Bottle and store in a dry place.

MUSIC. The Greek *μουσική* (sc. *τέχνη*) from which this word is derived was used comprehensively for all the arts of the Nine Muses. Contrasted with *γυμναστική* (gymnastic) it included the culture of the mind as distinguished from that of the body. Thus the singing and setting of lyric poetry formed but a small, if a central, part of a "musical" education which ranged from reading and writing to the sciences of mathematics and astronomy besides all the arts of literature. The philosophers valued music both in the ancient general sense and in our restricted sense, chiefly as an educational element in the formation of character; so that we obtain little light from them on the pure aesthetics of the Greek art of musical sounds.

1. INTRODUCTION

The present article deals mainly with the musical art-forms matured by European civilization since the 14th century. More ancient music is discussed frankly as beyond our power of appreciation except in the light of prehistoric origins. Our Western art of music stands in the unique position that its language has been wholly created by art.

Music owes but little to nature in the form of acoustic science, and still less to the sounds that occur outside works of art. It is already a mature musical art that selects the acoustic facts, just as in painting it is art that determines the selection of optical facts. Wise critics have, since Ruskin's day, abandoned the attempt to settle *a priori* how much of nature an aesthetic system ought to digest; and music differs only in degree from literature and the plastic arts as to independence of nature.

Yet the difference is often important. Perspective existed as a science before it was taken up by painters, and as a human experience before it became a science. The naïve Western spectator has seen enough of it in pictures to make him resent its neglect, whether in modern art or in the masterpieces of China and Japan. In music the nearest analogy to perspective is the system of tonality developed by the great composers from Alessandro Scarlatti to Wagner. (See HARMONY.) Every step in its evolution has been fiercely contested; and even twenty years after the end of Wagner's long career not every responsible musician was ready to admit Wagnerian tonality as a legitimate enlargement of the classical system.

If we set aside language and the organized art of music, the power of distinguishing sensations of sound is no more complex than the power of distinguishing colours. On the other hand sound is the principal medium by which most of the higher animals both express and excite emotion; and hence, though until codified into human speech it does not give any raw material for elaborate human art, it suffices for bird-songs that are as long prior to language as the brilliant colours of skins, feathers and flowers are prior to painting. Again, sound as a warning or a menace is an important means of self-preservation; and it is produced instantly and instinctively.

All this makes musical expression a pre-human phenomenon in the history of life, but is unfavourable to the early development of musical art. Primitive music could mysteriously re-awaken instincts more elemental than any that could ever have been appealed to by the deliberate process of drawing on a flat surface a series of lines calculated to remind the eye of the appearance of solid objects in space. But the powers of music remained magical and unintelligible even in the hands of the supreme artists of classical Greece. We may be perfectly sure that if the Greeks had produced a music equivalent to the art of Palestrina, Bach or Beethoven, no difficulty of deciphering would have long prevented us from recovering as much of it as we have recovered of Greek literature. Some enthusiasts for Oriental lore assure us that long ago the Chinese knew all about our harmonic system but abandoned it after they had exhausted it. This need not worry us. The Oriental aristocrat conceals in his politeness a profound contempt for our efforts to patronise his culture; and that contempt is justified when we show such ignorance of our own music as to suppose that a music of similar calibre could have utterly

disappeared from a living nation whose most ancient plastic art and literature commands our respect and rewards our study. When we trace the slow and difficult evolution of our harmonic system we cease to wonder that it was not evolved sooner and elsewhere, and we learn to revere the miracle that it was evolved at all.

2. NON-HARMONIC AND GREEK MUSIC

Music before the rise of a harmonic system is of two kinds, the unwritten or extemporaneous, and the recorded or scientific. At the present day the music of races that have not acquired Western harmony often pleases us best when it seems most extemporaneous. Tradition can go far to fix the forms and even the details of a performance that may, without the aid of words or dance, last for hours. With words or dance, music becomes more capable of being fixed by writing; but the first musical problems are as far beyond conscious reasoning as the origins of language. Birds solved them before human beings; and folk-music can show real beauty when the systematic music of its day is arbitrary and uncouth. Moreover, folk-music, together with the present music of barbarous races and Oriental civilization, can give us materials such as anthropology uses in reconstructing the past from its vestiges in the present.

For us the music of ancient Greece is by far the most important branch of musical archaeology. Unfortunately the approach to this most difficult subject has been blocked by lack of co-ordination between scholarship and musicianship; and the ascertained truth is less instructive to the general reader than the history of opinions about it. These opinions begin to be interesting when they are expressed by musicians whose music we can understand. The natural tendency of such musicians was to suppose that Greek music was like their own; and each advance in knowledge is marked by disillusion. The first difficulty presented by ancient Greek writers was sufficiently disconcerting. The Greek terms for "high" and "low" were found to be reversed. Our own meaning seems founded in nature; and science confirms it. Our "high" or "acute" notes demand tense vocal cords and correspond to vibrations of "high" frequency. A great 16th century composer, Costanzo Porta, inferred a mystery here, and argued that the Greeks had mastered the art of a totally invertible polyphony, such as Bach afterwards displayed in two fugues in *Die Kunst der Fuge*. Porta accordingly wrote a 4-part motet (*Vobis datum est cognoscere mysterium*) which could be sung upside down: and his contemporary Vincentino composed 4-part motets in each of the three Greek *genera*, diatonic, chromatic and enharmonic. (See Hawkins's *History of Music*, i. 112, seq.) They are as good as any other music written on *a priori* principles, and the enharmonic motet may be commended to some of our modern experimenters in quarter-tones. But they represent as much knowledge of Greek music as we possess of the inhabitants of Mars.

The truth must be sought by other methods and by far the most promising is the study and comparison of the present scale of nations, whether barbarous or cultured, who have not come into contact with the classical harmony of the West.

A readable account of musical origins may be found in Parry's *Evolution of the Art of Music*. Following the researches of A. J. Hipkins and A. J. Ellis, Parry illustrates the fact that most of the primitive scales, notably the pentatonic scales prominent in Scottish and Chinese music, are built around the interval of a downward 4th (as from C to G) which was probably the first melodic interval to become fixed in the human mind as being simple enough but not too wide. A scale would begin to form by the accretion of other notes near the bottom of this interval. Now take another 4th with similar accretions below the former, either conjunctly (as G to D below the C-G) or disjunctly (as F-C). The resulting scale will either fill or include an octave, it does not matter which; for the filled octave of the conjunct tetrachord contains in another position the notes of the included octave of the disjunct tetrachords, as can be seen in the combined series C, A, G, E, D, C, A, G. And the octave was recognized from the outset as a limit after which a musical series repeats itself.

The Greeks had three *genera* of scale: the diatonic, the chromatic and the enharmonic. Of these the diatonic divides the tetrachord most evenly, as E, D, C, B:A, G, F, E. This gives us our diatonic scale in what Palestrina would call the Phrygian mode. The Greeks found that all its notes could be traversed (as a knight's move can traverse our chessboard) in a series of intervals which they called concords. (They thought of them only as successions, not combinations of sound.) These were the 4th (in the ratio 4:3); the 5th (3:2); and the octave (2:1). (Our own "perfect concords" are in these ratios.) Scales with chromatic tetrachords (E, C♯, C♯, B:A, F♯, F♯, E) could also be traversed by the concordant intervals, but not so easily. The enharmonic tetrachords, which only the most accomplished singers could sing, were beyond the reach of perfect concords; and for us they would need a special notation, as E, C, B', B ; A, F, E', E♯; where B' and E' signify something like quarter-tones above the B♯ and E♯. Yet this difficult scale was said to be the oldest of all; which seems not unlikely when we observe that it gathers three notes closely to the bottom of the tetrachord, leaving a gap of a major 3rd from the top. Eliminate the quarter-tones, and there remains a pentatonic scale E, C, B:A, F, E, which is more likely to be the earliest filling out of the downward 4th than the scales in which the auxiliary note is a whole tone away. And if this nucleus had the prestige of a mystic antiquity musicians would feel a pious pride in mastering the difficulty of filling it up like the other genera.

If authorities on Greek music would abandon their habit of writing scales and reckoning intervals upwards, their results, whether correct or not, would become much more lucid. For, as Parry points out, it is only our harmonic system which makes us think of scales as normally rising; and when a musician applies the term "cadence" to chords that rise from dominant to tonic he contradicts the literal meaning of the word.

Until the most recent times classical scholars have ruthlessly closed the door upon all hope of further light from the comparison of Greek data with the phenomena of extant non-harmonic folk-song and Oriental scales. If such a comparison is to have any meaning we must assume that the now universal phenomena of modes existed in ancient Greece. Modes, as far as non-harmonic melody is concerned, are various cross-sections of a standard scale. Thus, Scottish music shows very clearly five pentatonic modes. Adding the 8ve to complete the scale, these are, 1. C, A, G, F, D, C; 2. D, C, A, G, F, D; 3. F, D, C, A, G, F; 4. G, F, D, C, A, G; 5. A, G, F, D, C, A. In the article HARMONY the ecclesiastical modes of pure polyphony are given with their fondly-imagined Greek names. Pre-harmonic music without modes is contrary not only to our Western prejudices but to the whole trend of anthropological research. In these circumstances classical scholars, under the guidance of D. B. Monro, crushed all hopes by deciding that the Greeks had no modes at all, but that either their *'apuvlai* or their *rovbi* (the terms, whatever they mean, are not synonymous) were mere transpositions of the three genera into various pitches, just as our "keys" are transpositions of our pair of major and minor modes.

When Monro published his *Modes of Ancient Greek Music* in 1894, musicians had learnt too well the lesson that Greek music must not be expected to make sense. They would never dispute a point of classical scholarship; and it did not occur to them that Monro might be just so innocently familiar with modern music as not to realize that he might as well impute high-church tendencies to Alcibiades because of "the splendour of his liturgies" as impute to the ancient Greeks a system of keys related by mere transposition. But musicians only thought that even the most unprejudiced anthropological comparison of extant scales could prevail no more than Macfarren's Victorian assumptions could do in a dispute with Monro. Fortunately in 1916 Mr. G. H. Mountford, in a degree thesis, satisfied classical scholars that Monro was in error and that the Greek modes were modes in the universal and proper sense of the term.

Miss Kathleen Schlesinger has found, by experiments with a monochord, a means of producing modes on mathematical principles. Certainly the Greeks did measure musical intervals mathe-

matically on a string; certainly Miss Schlesinger's system is among the very first things that could have happened in that way; and its results produce many phenomena that ought to have occurred in ancient Greek music. There is, for instance, a remarkable passage in Plato's *Republic* (VII., 531) where Socrates gibes at the pedantries of the merely practical musicians who spend hours in arguing whether this and that note are too near to allow another note between them. And Miss Schlesinger's various scales comprise between them notes quite close enough to explain how the practical musician could get into difficulties about what was obvious to the philosopher. Miss Schlesinger has, moreover, tuned a pianoforte on the basis of her theory, and the result is acoustically very interesting. So much then, for *a priori* theory and practical experience. If Miss Schlesinger's results are not Greek they ought to have been.

The other line of approach is through the experience of setting the choruses of Greek tragedy to a modern music which confines itself to a strict representation of the metre and sets strophe and antistrophe to the same melody. The composer should not attempt Greek modes, on whatever theory, or he will achieve nothing better than an effect of singing "We won't go home till morning" on the supertonic of a minor key and with a beat missing. Instead of thus warping his imagination the composer should translate all that modern culture enjoys in Greek poetry into a music that he can enjoy; restricting himself mainly to one note to a syllable and, while making his instrumental accompaniment as beautiful as he likes, straying into no by-paths of musical tone-painting other than the most natural symbolisms. The Greek rhythmic forms prove musically fascinating, and there is full scope for fine melody within them. The strict correspondence of strophe and antistrophe causes difficulties which reveal much. Even a unisonous accompaniment, such as the Greeks had, can glide over a difference of punctuation or indeed a running on of the sense between strophe and antistrophe, as at the end of the enormous first chorus of *Agamemnon*; and the technique of such compromises closely resembles that of Schubert and Brahms in strophic songs, and has the subtlety of Greek simplicity. Aristophanes, in the *Frogs*, laughs at the interlinear *θπαρτο θπαρτο θπαρτ* (or "plunketyplunk") of the Aeschylean lyre. The passage seems to indicate something more extensive than a merely connective tissue; but exaggeration is not unknown in comedy.

More difficult and therefore still more instructive are the occasional contrasts of sentiment between strophe and antistrophe. In another chorus in *Agamemnon* the pretty ways of a lion-cub are to be sung to the same music as the tale of disaster that befell the man who adopted it when, on growing up, it behaved as might be expected. The highest point of pathos in the first chorus, one of the supreme things in poetry, is the moment where the description of the sacrifice of Iphigenia turns into a reminiscence of her singing in her father's halls and then runs on into the antistrophe, with the words "The rest I saw not, nor will I tell." After which the same music has to express the pious hope that the queen who now approaches shares the wishes of the chorus for the welfare of the land she holds in trust.

From Plato we learn that musicians degraded themselves by imitating the roaring of lions and the whistling of winds. But what was the Greek criterion for the singing voice? Certainly very different from ours; for Aristotle says that certain high-pitched modes (but what is "high" in this context?) are suited to the voices of old men. An age-limit is the only criterion the heartless modern critic has for the voices of old men. Be this as it may, the safest inference from it is that every educated Greek was expected to sing well as an integral part of the art of speaking well. Perhaps our modern contrast between the singing and the speaking voice did not exist. Nowadays it is not uncommon to find a high soprano speaking normally around the A or G below the treble staff.

(See also ARISTOTLE; ARISTOXENUS; EUCLID; PYTHAGORAS.)

3. HARMONIC ORIGINS

The latent harmonic sense of the Greeks is shown in the fact that their diatonic scale was amenable to the Pythagorean science

of harmonic ratios. And we cannot suppose that no notice was taken of the combined sounds resulting from reverberation in halls and caverns, or from striking several strings of the lyre at once. Yet the fact remains that outside the orbit of our own Western music of the last six centuries we know of no harmonic system that has advanced beyond drones below the melody and cymbals (our Authorized Version is right in reading "tinkling cymbal") or bells above it.

Music, as we now understand it, consists in the interaction of three elements as inseparable (but not as interchangeable) as the three dimensions of Newtonian space. The Greeks knew two, rhythm and melody, which are as ancient as human consciousness and evidently have their meaning for some other animals. But non-harmonic melody is a very different thing from melody that implies harmony. (See MELODY exs. 1 and 2 with their discussion.) When we hear an unaccompanied folk-song we involuntarily think of it as the top line of a series of harmonies. If it is really pre-harmonic it will prove unamenable to that interpretation, and then we shall think it quaint. Neither the quaintness nor the harmonic interpretation ever entered into its intention. Life is too short for Western musicians to devote much of it to the violent mental gymnastics of thinking away the harmonic ideas that have made Western music enjoyable throughout five centuries. We may perhaps widen our experience by going back another two centuries; for it was agreed by all the musicians in Vienna that a concert of "Gothic" music was their most interesting musical experience of the year 1928.

In the article HARMONY the main steps are indicated by which mediaeval musicians advanced from doubling melodies in 4ths and 5ths (as the unoccidentalised Japanese are said to be doing now) to an aesthetic system of polyphony that demands complete independence in its melodic threads and forbids consecutive 5ths and 8ves as barbarous. The details of this evolution are abstruse; but two main issues may be mentioned here. Polyphony could not have been established without fixed scales and a repository of known melody for composers to work upon.

The scale was set in order in Graeco-Roman times by Ptolemy the astronomer, who flourished A.D. 130 and from whose time the history of the "ecclesiastical modes" becomes continuously traceable until the records of music are secured by the art of printing.

The necessary repository of melody was supplied by the ancient plain-songs of the church, many of which claimed to have come uncorrupted from the music of Solomon's temple and certainly had a continuous history reaching back to early Christian services in the catacombs of Rome. In A.D. 384 a large body of these "tones" was set in order by St. Ambrose. According to a tradition accepted, after some "historic doubts," by good authorities, St. Gregory revised and enlarged the Ambrosian collection; and the whole corpus of Gregorian music undoubtedly familiarizes Roman Catholics of to-day with a music enormously more ancient in its origin than any harmony. This music forms the principal melodic foundation of Palestrina's polyphony; but by his time it had become corrupted, and we must look to the Solesmes edition of 1904 for the text and method of singing plain-song in the perfection it is held to have attained shortly after the death of St. Gregory. The essential difference between the Ratisbon tradition (which we may loosely call Palestrinian) and that of Solesmes is that the Palestrinians impatiently curtailed the flourishes of the plain-song much as Palestrina did with the Gregorian themes he used in polyphony; whereas the Solesmes method restores the free speech-rhythm which makes the flourishes (or melismata) possible in a rapid delivery. Some of these melismata are very extensive, and the Palestrinians (who gradually developed the modern organist's habit of providing each note of a Gregorian melody with a separate chord) had some excuse for mistaking them for corruptions of style.

The Gregorian tradition did not stand alone. There was an ancient Visigoth (or "Spanish") tradition; and there are the traditions of the Eastern Church. Professor J. J. W. Tillyard has shed much light on Byzantine music (*q.v.*), including a promising opening in the deciphering of the earliest *Neumae*, diacritical signs above the words, supposed to indicate musical notes.

He uses the method of interpreting the past from vestiges of primitive usage in the present. Controversies as to the number of modes, whether 8 or 12, raged till late in the 16th century. The *Dodecachordon* of Glareanus settled the question in favour of twelve, as its name implies. Meanwhile composers developed polyphony by ear and got no help whatever from the theorist. Quite independent of modes and entirely practical was the hexachord scheme (see HEXACHORD) developed in the 11th century by Guido d'Arrezzo (q.v.).

The general reader may learn something of the hexachord system very pleasantly from the music-lesson in *The Taming of the Shrew*. Hortensio's gamut says "Gamut am I, the ground of all accord . . . D sol re, one clef [i.e., sign, or key], two notes have I: E la mi: show pity or I die." "Gamut" is a survival of Greek tradition; for the bottom note of the Greek scale was identified with the bass G, and this "ground of all accord" is an octave below the Ut of the hard hexachord. Hence it is Gamma-ut. D is Sol in the hard hexachord {G, A, B, C, D, E} and Re in the natural hexachord {C, D, E, F, G, A}. It has two names but only one position or "clef," unlike B which has to be flattened in the soft hexachord (F to D). (Morley writing in 1597, calls a flat the B clef.) E is La in the hard hexachord and Mi in the natural hexachord.

Between Fa of the natural hexachord and Mi of the hard hexachord a dissonant tritone 4th exists. It gave great trouble to mediaeval musicians, who assigned it to the devil. *Mi contra Fa est Diabolus in Musica*.

To the early harmonic and contrapuntal processes alluded to in the article HARMONY some details must be added. The famous unwritten songs of the aristocratic troubadours or *trouvères* of the 12th and 13th centuries undoubtedly set the fashion in melody, and probably set it in the direction of *Sumer is icumen in*; that is to say, in the Ionian mode (that *modus lascivus* that is identical with our major scale) and in a lilting trochaic rhythm

Sumer is icumen in contains no technical feature that has not been found in other compositions of its period, but nothing within two centuries of it achieves either its euphony or its easy handling of canon in four parts on a canonic bass in two. Its consecutive 5ths which sound licentious to us were in its own day the sole justification of the scheme.

It confirms other evidence that the imperfect concords (3rds and 6ths) must have obtained squatter's right in music in spite of theorists; for a very early practice known as ghimel or gymel consisted in singing in 3rds. This is not merely doubling, for the 3rd must oscillate between major and minor according to its position in the scale; and this adjustment requires an advanced harmonic system. When scholars tell us that singing in 3rds was traditional in Britain before the Roman Conquest, we must demur, especially when they tell us (in *Grove's Dictionary of Music and Musicians*, 3rd edition) that we must not expect to find written records of "so simple a process." Similarly we must not expect to find ancient Greek written records of so simple a process as steam locomotion. Still, let us not be unduly sceptical as to the extent to which popular licence and unrecorded extemporisation could advance beyond all the theoretic lore that scribes will record.

The troubadours disdained both the practice of accompaniment (which they left to their servants) and the art of scientific or written music. Not until the time and work of Adam de la Hale, surnamed the Hunchback of Arras (c. 1230-1288) can we trace the development of the troubadour into the learned musician. Nearly a century later, when literature is unbending from its universal Latin and becoming truly universal by becoming vernacular, we find the poet Machault, who stands with Petrarca among Chaucer's masters in the technique of verse, producing music that marks a technical advance discoverable by grim toil of expert analysis. But so far we may pardonably dismiss all such

Ex. 1.

Sumer is icumen in.

(A) Leading part, followed by 3 other voices at distances of 4 bars.

Sing cu - cu. Sing cu - cu, nu.

archaic work (except *Sumer is icumen in*) with Burney's sly comment on the earliest piece of recorded music known to him: "It is not of such excellence as to make us greatly regret the loss of such music; though the disposition of those who were pleased by it may have been a great blessing to them." When music is too archaic or inaccessible to give us aesthetic data more may be learned from the disposition of those who were pleased by it than from its recorded technical data.

Before the middle of the fifteenth century music had passed for ever out of the stage at which we need know other things of the composer than his music. As early as 1437 an Englishman, John Dunstable, had acquired a European reputation. The Golden age of the 16th century had no use for archaic music, and Morley in his *Plaine and Easie Introduction to Practicall Musicke* quotes Dunstable much as we might now quote Bach if all Bach's works were lost except for traces of contemporary hostile criticisms and awe-inspired laudations. To call Dunstable the "inventor of counterpoint" is no better than to call Cadmus the inventor of the alphabet. But he is the earliest composer whose polyphony is in direct line with that of the golden age; for Dufay the first important master of the Netherlands, where the true polyphonic tradition was for long thought to have originated, is now known to have died in 1474, twenty-one years after Dunstable. And when Dr. Walker, in his *History of English Music* praises a motet by Dunstable for its extraordinary distinction of style, he is indulging in no pious fancies but is describing permanently intelligible aesthetic values. By the end of the 15th century counterpoint was substantially fixed, practice was still imperfect and aims were uncertain, but skill was increasing and in the 16th century we leave archaic music behind.

4. THE GOLDEN AGE

From this point onwards the history of music is best studied in the masterpieces of the art. Each period has its own art-forms. Articles relevant to the Golden Age are HARMONY, Section 3; INSTRUMENTATION, Section II; CONTRAPUNTAL FORMS; COUNTERPOINT; MADRIGAL; MASS; MOTET; with the biographies and critical notes on PALESTRINA; VICTORIA; LASSO; TALLIS; MORLEY; BYRD. See also AICHINGER, ALLEGRI, ANERIO (G. and F.); ANIMUCCIA; ARCADELT; BATESON; BENNET (J.); BULL; DESPRÉS (Josquin); ECCARD; FARRANT; GABRIELI (A. and G.); GENET (of Carpentras); GIBBONS; GUERRERO; HANDL (Gallus); HASLER; ISAAC (Heinrich); MARENZIO; MORLEY (Thomas); OBRECHT; OKEGHEM; SWEELINCK; TAVERNER; WELCKES, WILBYE.

The external history of music is not so easily brought into true relation with the art as popular legends would have it. Everybody is familiar with the story of the drying up of polyphony in the foolish ingenuities of Flemish contrapuntists until, at the behest of the Council of Trent, Palestrina wrote the *Missa Papae Marcelli* in a pure and single style which convinced the authorities that polyphonic music could be devout. The facts are not quite so simple. Undoubtedly there was a great deal of barren ingenuity in the work of the lesser Flemish masters; and the great Obrecht himself had written masses in which the liturgical text is drowned beneath five other texts which each voice sings to other plain-chants and themes of old songs. The secular tunes thus freely introduced were not always sung as *canti fermi* too slow to be recognized. Recognition sometimes even led to the singing of the original words. One old song, *L'homme armé*, became the string round which every possible ingenuity crystallized in the composition of the Mass. There is no reason to doubt that the state of church music both deserved and received the serious attention of the Council of Trent.

On the other hand, not all Flemish music was silly, and many of the quaintest "canonic" devices were really nothing but harmless cryptography applied to music that was composed on purely artistic lines. Burney discovered this when, with his usual *flair* for good illustrations, he quoted some dry ingenuities from Okeghem (or Okenheim) and followed them by the wonderful *Deploration de Jehan Okenheim* by that master's great pupil Josquin des Prés who is the first unmistakably great composer

and who has been well named "the Chaucer of music." No listener can fail to recognize, from anything like a competent performance, the spontaneous beauty and poetic depth of this music, throughout which, while the other voices sing an elegy in French, the tenor intones in Latin the plain-chant of the Requiem beginning on a note a *semitone* lower than the liturgical pitch, and continuing in the wailing melodic mode thus produced. Burney had the wit to see that the "canon" *ung demiton plus bas* did not mean that some other part was to answer the tenor in canon, but was merely the "rule" for reading the cryptogram, the tenor being written at the normal pitch.

Many Flemish devices are well calculated to give coherence or climax to a large composition. One voice may wander up and down the scale with a single figure and a single motto-text while the other voices tell their whole story in polyphony. For instance, declaim the words *Miserere mei Deus* in monotone rising one step just for the first syllable of *Deus*. Start on the fundamental note of the scale, and at intervals repeat the phrase a step higher each time. After reaching the 5th degree go down again. Josquin's *Miserere* is a setting of the whole 51st Psalm, woven round a tenor part entitled *Vagans* and constructed on this plan. It is one of the first mature masterpieces in the history of music. Palestrina's art is too subtle for rigid Flemish devices; but once, in one of his finest motets, *Tribularer si nescirem* he uses Josquin's *Miserere* burden in exactly Josquin's way. Lasso is thoroughly Flemish in both sacred and secular music; and in a motet on the resurrection of Lazarus he makes a soprano *Vagans* cry *Lazare, veni foras* from the beginning of the narrative until the chorus reaches these words, and joins in with them in triumphant polyphony.

We must not, then, be misled by the ecclesiastical tradition that condemns Flemish music wholesale. In any case the concern of the church authorities was liturgical rather than artistic. The bishops would have been for the most part glad enough to see Church music restricted to the note-against-note style of Palestrina's litanies, *Stabat Mater*, *Impropria* and last book of *Lamentations*. A very sublime style it is, and Tallis's Responses, in their authentic form, are a noble illustration of it. But, as Dr. Jeppesen (*The Style of Palestrina and the Dissonance*) has clearly shown, Palestrina's *Missa Papae Marcellus* shows special signs of being a deliberate demonstration that a high degree of polyphony can be reconciled with clear choral delivery of the words. Certainly the ecclesiastical authorities did not long succeed in preventing the use of secular themes in church music.

Many great musicians of to-day have a musical culture which ignores the Golden Age; and a knowledge of Palestrina is still considered, as it was in the days of Bach and of Beethoven, rather an out-of-the-way specialty. This is like a culture based on Latin and sceptical of Greek; good as far as it goes, but limited and cocksure like an 18th century gentleman's artistic impressions of the Grand Tour. An illustration of the most perfect style of the Golden Age is appended to the article MOTET.

5. THE MONODIC REVOLUTION AND ITS RESULTS

Until Palestrina's art attained its height, the path of progress in music for the best part of two centuries was that of purity. It was not the free and bold spirits but the idlers and dullards who broke rules and disliked contrapuntal forms. The Hispano-Roman style of Victoria and Palestrina was not everything. It was not secular (though Palestrina's madrigals make him as supreme in that form as in church music), and it was not, like our glorious English polyphony, experimental or racy of the soil. But it was metropolitan, and the boldest of our Tudor composers would have been no such fool as not to hold it supreme. But already before the death of Palestrina a new music was groping towards the light; and for this music the path of progress was no more that of purity than the path of omelette-making is that of the conservation of egg-shells.

Eve's apple was not more fatal to man's earthly paradise than the rise of instrumental music and dramatic solo declamation was to the hope of continuing the Golden Age of music into the 17th century. The revolution did not consist in this detail or that. To

*The distribution of the words is uncertain. Perhaps these repeated notes are a realistic sob.

say that Monteverdi "invented" the dominant 7th, or that anyone else invented it, or that any such invention could revolutionize music, is like saying that Shakespeare revolutionized drama by inventing strange oaths. The important point is not the technical names of the details but their meaning. When Lasso was young some experiments in chromatic music had been made by Cipriano de Rore, and were eagerly imitated by Lasso. But what is Lasso's object in being the first person to write such an out-of-the-way note as A#? Simply to express the words "*novum melos*." Very different from such intellectual playthings is the purpose of the powerful discords of Monteverdi's madrigal *Cruda Amarilli* and of the monodic lament of Ariadne which drew tears from the spectators of his opera *Arianna*.

The article MONTEVERDI contains further remarks on his importance and on his coincidence in place and time with the creators of the violin. (See also OPERA.) The Palestrina style henceforth became the rightful privilege only of those composers who, either having mastered it before monody arose, or, like our own Orlando Gibbons, living in regions too remote for it to penetrate, could still compose polyphonically from impulse and not from asceticism. Orlando Gibbons did, in fact, try some monodic experiments which are poor enough.

An impulsively eclectic composer is another matter; and in uncouth, illogical Germany a giant such as Schütz could almost fill the century before the birth of Bach and Handel, with a life's work ranging from the pure polyphony of his Venetian master Gabrieli to the exploitation of all his "astute friend" (*scharfsinniger Freund*) Monteverdi's new principles in most gigantic efforts in mixed vocal and instrumental polyphony. From Schütz we can extract no such system as that which makes Monteverdi a favourite subject in musical history; but in Schütz's chaos the elements may at any moment come together in some strange work of art that fits into no historical or technical scheme but speaks clearly to us through its own coherence. Schütz's "astute friend" always knows what he is doing and whither his work is leading; but, except in a madrigal here and there, which was not his proper business, he does not produce a convincing work of art so often as Schütz who seems to have no proper business at all. It is to the astute, logical Italians that we must look for the progress and consolidation of musical art in general during the 17th century; but we must not let the enthusiasm of historians make us think that such a century of progress was a period of great music. The historians themselves are apt to neglect the intrinsic values of the 17th century compositions and to estimate them merely for their tendency towards something that was to take convincing shape later. The early 17th century was, in fact, musically not unlike what we have so far experienced of the 20th; the eyes of musicians and music-lovers were at the ends of the earth prophesying Wagner, when all that the whole century could finally achieve was the *da capo* form of aria.

Monteverdi and his fellow monodists had, in no mood of caprice, moved in the one direction that was universally important for music; yet their formless declamation soon palled, and its method survived only by becoming codified into the formulas of RECITATIVE, which are happy idealizations of Italian speech-cadence, and which survive as dramatic idioms in all music even at the present day. The "invention" of recitative has been ascribed to this or that monodist, with as little room for dispute as when we ascribe the invention of clothes to Adam and Eve. Any vocal music which, whether from inability or from disinclination, avoids organizing symmetrical melody, will be called recitative. When Wagner was still a subject of controversy, critics on both sides used to say that *Das Rheingold* was all recitative.

Two tendencies converged to make music become formal after the "first fine careless rapture" of monody was spent. First, the dramatic stage, with baroque scenery in magnificent development as early as 1667, in Cesti's *Pomo d'Oro*, greatly encouraged the ballet; so that when serious musicians cultivated the stage they also cultivated dance-music. This, however, was less important than the rise of the violin. Monteverdi had already understood its importance; and one symptom of the decadence of

polyphony had been the growing habit of solo-singers to sing the top parts of madrigals with all manner of ridiculous flourishes. Persons less legendary than King Cole felt the fascination of the "tweedle-dee" of the fiddle; the great Dutch polyphonist Sweelinck (*q.v.*) used to adorn his organ works with passages of *imitatio violinistica*; and the last quarter of the 17th century saw the brilliant work of Biber with his queer abnormal violin-tunings, and the sober classical *sonate da chiesa* and *sonate da camera* of Corelli (*q.v.*). Artistically as well as morally this development of the violin was healthier than that of the voice, wherein coloratura singing tended to become an acrobatic monstrosity though it had first been regarded as a means of emotional expression. A talent for the violin was no danger to a boy; but a beautiful voice put a boy in deadly peril in an age when all the great opera-singers were *castrati*. Even Haydn had a narrow escape in his youth.

And yet there is, on the whole, more beauty than decadence in the vast mass of solo vocal music produced between 1630 and 1760. That period takes us from the advent of mature instruments and instrumentalized music to a time beyond the death of Handel. Except for the device of the ground-bass (see VARIATIONS) the first form that emerged from chaos organized itself on a method of balance between a solo voice and a group of instruments, together with a development of melodic form by means of a firmly-established classical key-system. The result was the classical aria, one of the most effective art-forms ever reduced to the capacity of normal musicians. It entirely destroyed the dramatic character of opera for a whole century; but this has been lamented with unnecessary vehemence. With the exception of the early monodic works and of Purcell's *Dido and Aeneas*, opera before Gluck is not an art-form at all; it is merely a name for the spectacular conditions under which the 18th century public could be induced to listen to a string of thirty arias by one composer who could either handle no other forms or find no listeners for them. The article ARIA shows the intimate connection of this form with that of the CONCERTO. Other art-forms developed in the 17th century for use in the 18th are discussed under CANTATA, OPERA, ORATORIO, SONATA, SONATA FORMS, and SUITE. Matters of style and texture are discussed in CHAMBER-MUSIC, HARMONY and INSTRUMENTATION. The articles on monodic composers include CACCINI, CAVALIERE, CESTI, PERI and MONTEVERDI, besides ARTUSI and BANCHIERI who wrote against Monteverdi's earlier works with well-grounded demonstrations of their subversive effect on pure polyphony. The survival of polyphony in grimy and pompous decadence is represented by Pitoni, and later and more as a renaissance by LOTTI. Early violin music is represented by BIBER and CORELLI.

The short career of PURCELL (*q.v.*) ends twenty years after the death of Schütz and ten years after the birth of Bach and Handel. Almost any random quotation from Purcell might be by a composer of the calibre of Bach or Handel. Purcell is one of the greatest contrapuntists that ever lived; one of the greatest inventors of themes; one of the greatest masters of declamation; and a completely mature master of early orchestration. And his fellows in the English music of the Restoration, Pelham Humfrey, Child and Blow were no mean spirits. Burney devotes an entire plate in his *History of Music* to examples of "Dr. Blow's crudities"; and later historians need look no farther afield for examples of intelligent prophesy. But our Restoration music lacks one thing; and that is power of composition. Purcell, in small dance-forms and short lyrics, is unsurpassable. But his only chance of getting through a sustained movement is when he writes on a ground-bass. In this fascinating forlorn hope of English music we see the fruit of nearly a century of bold endeavour ripening a generation too soon. Parry ascribes the patchiness of Purcell to the subtle humour of Charles II. in sending his best chorister to learn from Lully, the master of the French ballet-opera, how to write English church music. But Lully is not patchy, and Purcell's music is a crazy-quilt, purple with fore-shadowings of the music of the future.

6. BACH, HANDEL AND THE NEAPOLITAN SCHOOL

If all music between 1685 and 1759 were annihilated except the

work of Bach and Handel, the ordinary music-lover would miss nothing but a large collection of decorative and decorous violin music and a still larger collection of arias; and to most of these favourite *gemme d'antichità* the mid-19th century editor has contributed much of their lusciousness. For us the age of Bach and Handel is the age of nobody else in music. But the contemporaries of Bach and Handel thought of Handel as a fashionable opera-writer who with advancing years developed choral music as a pious fad; while nobody thought of Bach except people within a coaching-range of Saxony where Bach was known as a wonderful organist and an impracticably deep scholar. The polyphony of Bach and Handel stands almost alone in an age when polyphony was utterly unfashionable. It was inculcated as a staple subject in musical education; but to carry it into mature art was to discuss Latin grammar in the drawing-room. The opportunities and the difficulties of early symphonic orchestration alike arose from the neglect of polyphony after 1750. Apart from Bach and Handel, that neglect can be traced much further back; and it characterized musical connoisseurship much later; so that Burney could say of Philipp Emmanuel Bach that wherever he got his beautiful and natural style from it was not from his father, for that eminent organist, though profoundly versed in all devices of canon and fugue, was so fond of crowding all the harmony he could into both hands that he must inevitably have lost melodic grace.

The vast and accurately-perfected aesthetic system of Bach and the improvisatorial opportunist eclecticism of Handel are discussed in the articles on those masters, and also under the headings of ARIA, CANTATA, CONCERTO, CONTRAPUNTAL FORMS, COUNTERPOINT, FUGUE, HARMONY, INSTRUMENTATION, ORATORIO, SONATA FORMS and SUITE. But, while this information covers the aesthetic values of the period, it tells us little of its historic trend. We must not look for light from the "spirit of the age" as shown in its politics or even in its religious history. Palestrina writes, from habit and preference, a devout music which neither Luther nor the Council of Trent could blame as representing the spirit of the age; and Bach achieves the ideal Lutheran music while Voltaire is at the court of Frederick the Great.

The music that pleased the contemporaries of Bach and Handel was that which continued, not too elaborately, the Neapolitan tradition founded by Alessandro Scarlatti. Lully (an Italian by birth) took this tradition to France, and transformed Italian opera by encouraging the French taste for the ballet. Rameau, greatest of classical French composers and epoch-making theorist, carried on the Lully tradition in opera, and joined forces with the exquisite school of clavecinists, whose leader, Couperin, was admired and imitated by Bach in his suite-forms. Italian violin music and concertos in the Neapolitan style were produced by composers who were also great players. The enormous industry of Bach and Handel was nothing unusual. Arias could be written as easily as letters, and distributed by thirties in operas. Oratorios and church music, though less fashionable, were more highly organized; mainly because they kept choral music in being. And thus the Neapolitan tradition of choral music passes straight into the polyphony of Mozart, quite independently of Handel and wholly ignoring Sebastian Bach, of whom Mozart knew not a note until he was grown up. Meanwhile cultured Europe was untroubled by doubts as to who were the immortals. The Handel-Bononcini rivalry had been little more than a nine-days' wonder. Six years after Handel's death, the seven-year old Mozart in London dedicated his violin-sonatas to Queen Charlotte in the hope that under Her Majesty's protection "je deviendrais immortel comme Haendel et Hasse." Graun would probably have been the third name of European repute; and Telemann, the most voluminous composer of his voluminous day, was a great figure in his own country. As for Bach—everybody in London knew Mr. J. C. Bach, of the Bach and Abel concerts, and report said that his father had been a great musical scholar.

Behind the dignified musical history, but not (like Sebastian Bach) aloof from it, vital forces were at work in comic music-drama. This was admitted by way of *intermezzi* between the

acts of serious operas. One of these intermezzi, *La Serva Padrona* by Pergolesi (known in the 19th century by his conventional *Stabat Mater* for two-part female chorus) not only broke from its moorings, like many other intermezzi, but found its way to Paris where it created a furore of popular success and precious disputation dividing musical Paris into *Buffonistes* and *Anti-buffonistes*. Except for the untimely blossom of English opera in the hands of Purcell in the previous century this is the only moment at which opera after Monteverdi and before Gluck (with all respect to Rameau) becomes a genuine art-form instead of a concert on the stage.

Biographical articles dealing with the following named composers who belong to this period: the violin writers CORELLI, GEMINIANI and TARTINI; the clavier writers COUPERIN and D. SCARLATTI (the Paganini of the harpsichord and a most unclassical son of the founder of classical tonality); the opera writers (which meant the all-round musicians) DURANTE (Francesco), GALUPPI (who certainly never wrote Browning's "sixths diminished, sigh on sigh"!); LEO (Leonardo), PERGOLESI and SCARLATTI (Alessandro). RAMEAU is equally important in three capacities as a master of French opera, a livelier master of instrumental music, and an epoch-making theorist. German beginnings of serious and comic music-drama were sumptuously inaugurated at Hamburg by KEISER (*q.v.*) whose influence is traceable in Handel's first opera *Almira*.

7. THE RISE OF DRAMATIC MUSIC AND THE SONATA STYLE

The fashionable distaste for polyphony was a mere negative force in the early 18th century. The positive force was, as in the monodic revolution a hundred and fifty years earlier, an impulse towards drama. Unlike the monodists who, when they rejected polyphony had no power of composition beyond the single musical sentence, the 18th century musicians could easily cover ten minutes with a well-balanced form; and the problem of making such forms dramatic was no longer confined to the monodist's problem of making them rhetorical. On the contrary, the rhetoric had to be demolished; for the action of drama is not the action of rhetoric.

The distaste for polyphony was no unfavourable condition for the rise of dramatic music; it was the inverse aspect of a growing sense of contrast in various textures cheap and valueless in themselves. The rest of the story is told in the articles, INSTRUMENTATION, HARMONY, OPERA, SONATA FORMS, and GLUCK, BEETHOVEN, HAYDN, MOZART.

It is inadequate to call Gluck a "reformer" of opera. Music itself was not dramatic before Gluck made it so. Hence it is a mistake to separate Gluck's "reform" from the whole process of the development of the sonata style. Lastly, we miss the whole meaning of that style unless we realize that as soon as it arose the purely instrumental music became more dramatic than any drama. At the same time it also became more powerfully architectural than any earlier music. The art comprised in the works of Haydn, Mozart, and Beethoven constitutes one unbroken aesthetic system, more universal in emotional range than any art since Shakespeare, and as perfectly balanced as the arts of ancient Greece. Until the end of the 19th century it would have seemed a paradox to maintain that Beethoven's work belonged to the same aesthetic system as Haydn's and Mozart's; for critics were slow to escape from the habit of estimating works of art by the face-value of their subjects and the dignity of their language. And the language of Haydn and Mozart corresponds with that of the comedy of manners, while Beethoven is the most tragic composer that ever lived. Nevertheless the huge expansion which music underwent at Beethoven's hands was no revolution, and the popular idea of Beethoven as a revolutionary artist is based on two errors; first, the commonplace habit of seeking parallels between the works of genius and the personal eccentricities of their authors; and, secondly, the inadequacy of orthodox doctrine on musical forms. This inadequacy results from the fact that the doctrines are contemporaneous with the compositions and are accordingly hostile to all but the easiest conventions. A proper grammar of a classical art requires something of the attitude of

the unjustly-despised Byzantine scholars who sacrificed aesthetic pleasures in humble devotion to the task of securing the texts. It is when the languages are dead that they live for ever and suffer no corruption.

We need not expect scholarship in the orthodoxies that were current as to musical forms used in the lifetime of the classics themselves. (See *FUGUE* for a demonstration of the irrelevance of traditional doctrine on that art-form.) Still more impertinent is our orthodoxy on sonata-forms. It ignores the differences between Haydn and Mozart which are as radical as any innovation Beethoven introduced; and, having thus cut away all ground for appreciating Beethoven, treats him as the central symphonic classic, and also as a stupendous revolutionary. This result is correct as far as it goes: central classics can be stupendous revolutionaries. But correct pious opinions are the healthier for facts that can give us a right to them; and the beginning of the 19th century was unfortunately the beginning of an age of humbug in musical education. (See *CHERUBINI*, who, however, has other claims to our respect.) One consequence is that many a musical revolt purports to revolt against the classics when its nearest contact with classical forms has been the perky generalizations of textbooks by writers who regarded the great masters as dangerous, and who deduced their rules from the uniform procedures of lesser composers. Now these procedures were often derived from one or two popular works by the greatest men: thus Beethoven himself produced one model sonata (op. 22)—if its "first subject" had only been long enough. And if Mozart's great C major quartet had not such a subversive introduction it might (and did) serve as a jelly-mould for all the quartets of Spohr. Take another jelly-mould from Spohr, and you have classical tradition.

But now comes the fundamental difficulty in all attempts to distinguish the classical from the pseudo-classical. Every individual work must be judged on its own merits. No generalizations are trustworthy. Many movements by Mozart are as alike as peas. But, being alive, they are not as alike as buttons. With Mozart and Haydn the individuality of each work is all-important for the critic, and if he neglects this all that he says about the common form is superficial. On the other hand, the materials of Beethoven's work developed so rapidly that he seems to be driven to invent a new technique for almost each composition. Hence the external differences become obvious; and unless the critic penetrates to the common form he is lost.

With the symphonic classics we enter the period when these considerations become important; for there is no gulf between that period and our own. No musical art known to Haydn has suffered, like the art of Bach, a period of total eclipse; nor, on the other hand has it had preserved a character that Haydn could have understood. Not much light is shed on Haydn and Mozart by calling them court composers, and little more on Beethoven by calling him a child of the French Revolution. In an age of court patronage Bach the theologian had been inspired to write warlike music not more by ancestral memories than by scriptural texts of war in Heaven. Mozart and Haydn were restive in the service of courts and their musical language was that of the comedy of manners when it was not racy of the soil. In Paris, where musicians might be expected to know most about the French Revolution, the modest, lovable Etienne Méhul (famous for the biblical opera *Joseph*) produced his prettiest comic operetta *Le Jeune Sage et le Vieux Fou* in the year of the Terror; and on French music the immediate effect of these tremendous days was the rise of a new type of sentimental opera concerning the hair-breadth escapes and sufferings of the political prisoner rescued by the heroic wife. Hence Cherubini's *Les Deux Journées* (*The Water-Carrier*) and Beethoven's *Fidelio*. Genius is the wind that bloweth where it listeth. In Bach's day Beethoven would have been musical interpreter of the Apocalypse; and in this 20th century Bach would be something like Dr. Schweitzer.

When we contemplate the impassable gulf that separates Bach's art not only from Haydn's and Mozart's but from the apparently more kindred spirit of Beethoven, we find it hard to realize that contemporaries were unaware of any catastrophic development.

In the case of choral music a little study shows us that its forms and language remained Neapolitan. Haydn's and Mozart's masses are flamboyant Neapolitan music; and Michael Haydn, who was merely decorative as an instrumental composer, was rightly thought by his brother to be the better man at church music. Again we regard Philipp Emmanuel Bach as bridging the gulf between his father's and the new art; but Philipp Emmanuel was writing quite mature sonatas in the year of his father's B minor Mass and his last set of sonatas was produced in the year of Mozart's *Don Giovanni*. Clementi, born in the year after Bach's death, was an infant prodigy of eight when Handel died; he had developed an extraordinarily massive and genuine pianoforte technique (more powerful than beautiful) when he encountered Mozart in a musical tournament, and he survived Weber, Beethoven and Schubert. Nothing can be gained by a further attempt to summarize this "Viennese" period. We may call it the period of the sonata and of Mozartean comic and French romantic opera. More particular information is given in the following technical and categorical articles: *HARMONY* (on Key-relations); *INSTRUMENTATION*; *MELODY*; *OPERA*: *ORATORIO*; *OVERTURE*; *RONDO*; *SCHERZO*; *SONATA FORMS*; *SYMPHONY*; *VARIATIONS*, and the biographies *ABEL* (K. F.); *BACH* (C. P. E.); *BEETHOVEN*; *BENDA*; *BOCCHERINI*; *CHERUBINI*; *CLEMENTI*; *DITTERSDORF*; *DUSSEK*; *GLUCK*; *HAYDN* (J. and M.); *MOZART*; *PUCCINI*; *SCHUBERT*; *SPOHR*; *WEBER*.

8. THE ROMANTIC PERIOD

Romance brings us to the composers who developed lyric music in the forms of songs and short pianoforte pieces. Schubert, Weber, Spohr, Mendelssohn and Schumann would be the romantic composers in this sense, and many contemporaries would have added Cherubini to the list, for they thought of him not as the martinet who directed the Paris Conservatoire but as the composer of *Les Deux Journées*.

But this list traverses another sense of the term which opposes the romantic to the classical. The classical is in this connection identified with both formalism and mastery. Mendelssohn and Spohr chose romantic subjects to no purpose; their mastery was unromantically slick (there is no other word for it) and Spohr's forms were more thoroughly ascertained than anybody else's except those of Mozart's brilliant pupil, J. N. Hummel. Mendelssohn's forms were free; but he never got into difficulties, so how could anybody recognise his freedom? Philipp Emmanuel Bach's vein of sentimental rhetoric was not only typically romantic but enabled him to write some genuinely lyrical songs. Schubert was another romantic writer who influenced Mozart at an impressionable time of his boyhood. Every thrilling modulation in Beethoven's music was romantic, and so were the double-bass passages at the beginning of Cherubini's overture to *Les Deux Journées*.

The romantic period is more interesting than this generalization. There is a real line of cleavage, other than mastery, which ranges Spohr and Mendelssohn on one side and Schubert, Schumann and Chopin on the other. Beethoven's vast enlargement of the art of tonality and the concentration of his later polyphony had made music ready for lyric forms which he himself adumbrated in a few of his bagatelles for pianoforte and some sporadic good things in his songs. Mendelssohn and Spohr took up song-writing and produced in that line masterpieces for the drawing-room. We ought not to despise the drawing-room. Schubert became the supreme master of song, and Schumann achieved greatness there as in his pianoforte lyrics; but you might as well think of Keats and Shelley as writers for the drawing-room.

Another line of cleavage separates Schubert from Schumann and Chopin as fundamentally as it separates him from Mendelssohn and Spohr. When Schumann and Chopin handle the large classical forms they show obvious weaknesses. Schumann makes an effective new artificial sonata form out of his stiff antithetic epigrammatic style, as a man might construct a landscape in mosaic. Chopin merely shows that he has taken the sonata forms uncritically from Hummel, though the first two movements of the B flat minor sonata are almost as happy in their classical form as the Ballades are in Chopin's unique way. But Schubert's large

forms have only the weaknesses of youth, and their positive qualities and tendencies set him above all schools and indicate that if he had lived we should not so readily have closed a historic chapter with Beethoven. The mastery that Schubert lacks is not anything that Spohr could have supplied. Younger composers with new worlds to conquer could with some truth accuse Spohr of playing with classical forms as one might play chess; but they could never have so accused the Schubert that died young or the Schubert that might have reached old age.

We do not know what Mendelssohn might have achieved if he had lived longer. His influence on the musicians he knew personally was wholly stimulating and good. But he too, seemed able to play chess with symphonies, oratorios and songs with and without words, while other composers were grappling in their music with real life, perhaps confined to one narrow art-medium like Chopin, or, like Schumann, deserting lyrics for larger forms or some artificial hypothesis, or, like young Berlioz, kicking right and left against all teaching and all criticism while dreaming new wonders of orchestral sound, and correctly dreaming the practical means to them also.

Meanwhile a greater than Berlioz was arising, a dreamer of new sense as well as of sound. Mendelssohn and Schumann saw only the beginning of Wagner's development, and could not feel very sure that this voluble and stormy reformer of music-drama was really likely to achieve anything better than the tinsel of the astute Meyerbeer who dominated the world of cosmopolitan opera. The early style of Wagner is indeed an alloy of many metals besides iron and potter's clay; but even in the 'forties his work marks the eclipse of the first romantic period and the dawn of another and greater epoch.

The art-forms peculiar to the Romantic period have no definite names, though composers began to use many literary titles, such as Ballade, Romance (already used by Mozart for slow movements in sonata-form), Nocturne and the like. Dance-rhythms, especially those of Poland, were brought into prominence in the pianoforte music of Chopin. Mendelssohn's invention of the song without words was very successful, but the notion is too facile to lead far, or always, even in Mendelssohn's hands, to justify its existence. Fantastic titles, used in the 18th century by the French clavecinists, assumed great prominence in the pianoforte works of Schumann who created a new type of long connected cycles of epigrammatic little pieces. The articles PROGRAMME MUSIC and SONG concern this period vitally. Relevant biographical articles are CHOPIN, MENDELSSOHN, SCHUBERT, SCHUMANN, SPOHR, WEBER; while the crowd of pianoforte composers whose brilliance on that instrument obstructed all wider musical prospects, include the respectable HUMMEL, the less respectable STEIBELT, the flimsy WOELFL and the Irish writer of beautiful pre-Chopin nocturnes, FIELD (John).

9. THE WAGNERIAN DEVELOPMENT AND THE RENASCENCE OF CLASSICAL FORM

Wagner formulated his principles of music-drama long before he matured his musical style. It is impossible to understand the musical history of the second half of the 19th century until we frankly admit that the composers of instrumental music saw in Wagner not only the subversive operatic theorist and erotic dramatist but the composer who was popular because of the salvation-army religiosity of the end of the *Tannhäuser* overture and the downright vulgarity of the entr'acte before Act III in *Lohengrin*. His theories and methods might be controversial, but these lapses never were.

Strange to say, Wagner received something like recognition from the doyen of classical champions, Spohr, whose attitude to Beethoven had been merely condescending, but who saw in *Der Fliegende Holländer* and *Tannhäuser* interesting, if faulty, works which well deserved painstaking production at his theatre at Cassel. Schumann too, after joining in the general hostility towards *Tannhäuser*, frankly recanted and praised its many noble features. Personally he and Wagner did not get on so well; he found Wagner too talkative and Wagner found that Schumann had nothing to say. Later on when Wagner was in exile, *Lohengrin*

found a powerful champion in Liszt at Weimar.

Liszt presented another problem to sober musicians. Wagner himself at first saw nothing in Liszt but the virtuoso who, when asked for music, would give you a fantasia on *Robert le Diable*. On the other hand, persons who became bitterly hostile to all the musical tendencies that Liszt fostered went out of their way to declare that no such wonderful interpretations and technique as Liszt's pianoforte playing had ever before been heard on any instrument or orchestra. All Liszt's gestures were superb, from his monumental immobility at the pianoforte to his princely and often really self-sacrificing generosity to other musicians. And at the age of 37 he made the most superb of all his gestures in giving up playing in public. And so the one incontrovertible power of his art became a legend and his actual activity became the championship of unorthodox artists. He took to composing on a more ambitious scale than that of the marvellous pianoforte virtuoso; and became himself the leader of a new development of romantic music. Although he took little pleasure in counterpoint he had none of Berlioz's clumsiness in harmonic texture; and his orchestration, in which his first efforts had the secret assistance of Raff, was always brilliant and novel, though it never caught the Berliozian fire or plumbed the Wagnerian depths. Liszt realised no more than Berlioz the true musical purport of the new ideas which his symphonic poems and Berlioz's symphonic-dramatic phantasmagorias were putting forward under all kinds of literary and pictorial names. While the new romantic composers purported to be devoting instrumental music to the illustration of literature (see PROGRAMME MUSIC) they were really struggling with a new musical time-scale.

As we have already seen in the present article and in the discussion of HARMONY, musical history may be traced in terms of the time-limit over which the listener's memory is brought into play. In the 16th century that limit is from accent to accent; by the end of the 17th century it ran from phrase to phrase. The great architectural forms of Bach could stretch it easily to six minutes, and, in extreme cases to ten. The rise of the dramatic sonata style did not greatly enlarge the time-scale; for there are few well-constructed sonata-movements that exceed a quarter of an hour, though on no smaller scale could Beethoven have prepared the famous harmonic collision that gave such offence in the first movement of the Eroica symphony. Now this ten-minute time-scale obviously compelled musicians to handle the action of an opera by means of conventions. (See OPERA.) It is less obvious that it also produced a similarly conventional artifice in the relation of sonata-forms to their emotional content. A design may complete itself in ten minutes while raising emotional issues that cannot be dealt with in less than forty. And so the sonata-forms are grouped in from two to four (rarely more) movements as artificially as the musical sections of classical operas. Wagner's enormous achievement in music-drama consisted essentially in giving music the same time-scale as that of the drama. As with all first solutions of an art-problem he achieved an extreme case, for his drama became cosmically slow. But from *Das Rheingold* onwards every Wagnerian opening instantly, and without any introductory gestures, lays down the lines of its vast time-scale, to the utter bewilderment of his contemporaries who continued to expect *Das Rheingold* to show its pattern on Beethoven's time-scale, just as Beethoven's contemporaries had heard seven *pianissimo* bars on the chord of E flat, not as that vaulted vacancy appears in the middle of the andante of the C minor symphony, but as it would have sounded if it were intruded into an andante by Mozart.

Nobody else before Richard Strauss achieved Wagner's mastery of his new time-scale; and few, if any, of his contemporaries, whether hostile or friendly to him, realised its existence. Liszt was trying, in his symphonic poems, to make a music that filled its half-hour or forty minutes continuously; but his first effort of the kind, *Ce qu'on entend sur la montagne*, spends the first twenty of its forty minutes in a series of introductions, and the remaining twenty in retracing the series backwards. And his more successful efforts, such as *Orpheus* and *Les Préludes*, are either essentially lyric or not on the new time-scale at all. He never achieved so

effective a symphonic poem as Schubert had already long ago unwittingly produced in the "Wanderer" fantasia. Musicians who might not have been repelled by new doctrines of musical form found Liszt's style even more demi-mondaine than that of the early works of Wagner; nor did Liszt show any tendency to purify it. Moreover he rivalled Meyerbeer in the efficiency of his press-bureau by which he made propaganda, often in his own fluent French, more generously for others than for himself.

Meanwhile another musical development was arising, conscious of its continuity with the past, and, like Judaism as defined by Mathew Arnold, tinged with emotion in the morality of its aesthetic principles. Joachim, as great an interpreter on the violin as Liszt on the pianoforte, at first found in Liszt a congenial friend, until he saw his compositions. These horrified him, and the horror completed an estrangement already begun by his dislike of the atmosphere of Liszt's press-bureau. He and his younger friend Brahms were united not only in general musical taste but in personal devotion to the heroic widow of Schumann, who, after her husband's tragic and lingering death, was bringing up a large family on the proceeds of her concerts. These three artists soon came to regard the musical atmosphere of Weimar, where the *Lisztianer* gathered around their master, as unhealthy. In the correspondence and mutual criticism of Brahms and Joachim the word *Lisztisch* became synonymous with "devilish"; and indeed it is true that any characteristic Lisztian and many Wagnerian idioms would have a disgusting effect if intruded into Brahms's music. To-day we can be wise after the event and find matter for regret in the drastic out-spokenness of Joachim and Brahms which elevated matters of taste into questions of artistic honour. If Liszt could have been contented with *sachlich* criticism on definable issues of technique without requiring attestations of sympathy and enjoyment, and if Joachim could have resolved matters of taste into questions of artistic proportion, the neo-classical and neo-romantic musicians would have joined forces instead of condemning each other. Similar economies might be effected in nature if lions could be converted to vegetarianism.

The controversy was unequal, in two compensating ways. Wagner had a tremendous, if acrid, fluency in prose and did not care where his vitriol might alight. Moreover, Wagnerian and Lisztian music was much easier to write about, whether in attack or defence, than music which had no literary aspect. Brahms, like Wagner, needed and found friends who adored his music, but he hated the idea of a press-bureau and snubbed anybody whose compliments aroused the least suspicion of flattery. These drawbacks had their own compensation. It might be difficult to write as interestingly about Brahms as about Wagner; but Wagner, whether in exile or enthroned at Bayreuth, had Wagnerian music-drama as his whole province, while Brahms reigned over the whole of the rest of music, instrumental, choral and lyric. If criticism came to persecution, on the whole the neo-classics had the worst of it; for Brahms had no equals since Joachim gave up composition, and the position of a champion of classical forms was easily confused with that of a persecutor of the prophets of progress. As a matter of fact, Brahms was no anti-Wagnerian and was annoyed when his friends bracketed Wagner with Liszt.

But, apart from the clash of flying inkpots, the recognition of Brahms was assured by two facts; first the propaganda of his work not by words but by consummate and authoritative performance, and second, the very fact that his music required an experienced love of music for its understanding. A man might become an enthusiastic Wagnerian or even a well-equipped conductor of Wagner's music and be as the brutes that perish about symphonic orchestration, choral music, chamber-music, songs and all pianoforte music except Chopin. But it was long before any musician could venture to tackle Brahms's music on any basis except that of the most comprehensive musical culture and technique. Brahms lived long enough to become worshipped unintelligently; and after his death (in 1897) the reaction was more evident than the fashionable worship had been. There are signs that the reaction is over by now.

The Wagnerians felt deeply that their propaganda was incomplete for lack of a master of purely symphonic music. This they

found in Bruckner (*q.v.*). Brahms was appalled by the clumsiness of Bruckner's forms, and the most official Wagnerians admitted the frequent lapses of their symphonic master. On the other hand Bruckner's Nibelungen-tetralogy openings to his symphonies obviously dwarfed the terse themes of Brahms. By the time Brahms and Bruckner had come into their own, the public had long lost all sense of form in its appetite for bleeding gobbets of musical butcher's-meat hacked from the living body of Wagnerian music-drama and served up in concert rooms as *Waldweben*, *Karfreitagszauber* and *Walkürenritt*. After this it was pectentry to quarrel with any symphonic composer's form so long as his openings were vast enough. Brahms was no pedant; obvious weakness of form and style did not deter him from being the first to recognize Dvořák (*q.v.*); and he was drastic in his rebuff of anybody who thought to flatter him by talking against Wagner.

The song-writer Hugo Wolf (1860-1903) became recognized too late to be made use of as a lyric-pawn in the Wagner-Bruckner party politics of music. As far as his theory of song can be summarized, it consists in the application of Wagnerian declamation to lyric poetry. If his practice were not better than this essentially prose theory of verse-rhythm (*see RHYTHM*) and the perky censorship of classical musical declamation that goes with it, Hugo Wolf's art would not have survived his short and ailing life. But it is deeper than the theories on which it is supposed to rest and its apparent revolt from lyric melody only partly conceals a powerfully organized lyric form, and does not at all conceal a great gift of characterisation.

10. NON-GERMAN MUSIC OF THE 19TH CENTURY

While these great issues were being debated in Germany, the music of other countries was awakening from long sleep or outgrowing infancy and provinciality. France had, since Rameau, been remarkably content to have its music dominated by foreigners. Before Rameau, French opera was established by the Italian Lully. After Rameau it was reformed by the Austrian Gluck. Early 19th century French classicism was dominated by the Italian Cherubini. Another Italian, Rossini, was in the prime of his life absorbed by Paris; and the result was *Guillaume Tell*, with its rich orchestration and grandiose forms. But the crown of French opera was imposed on it by the German Jew Meyerbeer. The pretensions of the native French composers were more modest, except for the volcanic eruptions of that typical Gascon Berlioz. The popularity of Gounod (1818-1893) rested on the same misunderstanding of the meaning of art as the vogue of Doré in the capacity of an illustrator of the Bible. *Faust* was a success. Another development, more improvisatorial, uncertain of its style, but fundamentally sincere, was initiated by the Belgian, César Franck (1822-1892) (*q.v.*). From him, and not from the more prolific and facile Saint-Saëns, originates the main stream of modern French music. His style has too much affinity with Liszt to please the musicians who continue to regard Liszt as the author of all modern musical evil; but he achieved mastery in a wide range of forms all his own and he never wrote for effect.

In Italy music since Rossini was long contented to imitate the things in which Rossini was imitable. These were the mechanical cultivation of *bel canto* and the use of a full orchestra to support the voice in a thick unison of the melodic instruments, with a brassy dance-rhythm in the rest, and the big drum and cymbals to mark the rhythm. The genuine melodic inventiveness of Bellini and Donizetti did little to improve the other categories of the art; but in Verdi (1813-1901) a new genius was arising together with the Risorgimento. In *Rigoletto*, *Il Trovatore* and *La Traviata* Verdi's dramatic sincerity triumphs over the defects of a musical texture which still clings to traditional squalor, though strokes of genius occur unpredictably in the orchestration of many passages. In *Aida* the style silences all cavi; and in *Otello* (written at the age of 74) and *Falstaff* (written at the age of 80) Verdi creates a new kind of opera, Wagnerian in its perfect continuity and dramatic movement, but utterly independent of Wagner's style and method.

Bold prophets in Beethoven's time had been heard to say that a great musical future was in store for Russia. The fulfilment of

this prophecy was long delayed, for when Rubinstein averred that Michael Glinka (1803-1857) was the equal or the superior of Haydn and Mozart he expressed an opinion which could have occurred only to a Russian, and then only as a patriotic paradox. Rubinstein himself achieved only a weak cosmopolitanism in his voluminous compositions, though his pianoforte playing remained, for all its waywardness, till near the end of the century, as the most monumental power of interpretation on that instrument since Liszt. The first composer to make a genuinely Russian music recognized over the whole civilized world was Tchaikovsky (1840-1893) whose symphonies were held by some critics to have eclipsed those of Brahms. This was the eclipse of drama by melodrama. The true merits of Tchaikovsky are now eclipsed by the rising reputation of his less immediately successful contemporaries. Moussorgsky (1835-1881) had the posthumous fortune to have his two great operas *Boris Godunov* and *Khorantschina* revised by Rimsky-Korsakov (1844-1908) the most brilliant contemporary master of pure orchestral colour and texture. This was unquestionably good fortune in so far as it speeded these unconventional works on their way into the wide world; but something like indignation has accompanied the more recent study of Moussorgsky's original scores, with the discovery that besides altering clumsinesses Rimsky-Korsakov constantly meddled with features in his friend's style that were far beyond his comprehension.

The 19th century was over before any musician on the continent could be persuaded that there were composers in England. Schumann had repeated St. Gregory's pun about Angels and angels when he hailed Sterndale Bennett as "ein englischer Komponist"; but the trials of English musical life dried Bennett up. All who knew and loved him denied hotly that his music reflected Mendelssohn's; and perhaps, to-day, a leisurely study of it might vindicate his independence. Macfarren (1813-1887), who succeeded Bennett in his educational offices, was a widely-cultured musician whose influence for good was frustrated by his violent conservatism which co-existed with a fatal readiness to be led by faddists. (See HARMONY.) The renaissance of English music began in the work of Parry (1848-1918) and Stanford (1852-1924). They put an end to the provincial absurdities of our British oratorio tradition, and consistently set great literature in a way that revealed to contemporary poets that the antithesis between musical and general culture was false. They also had wide and deep influence as teachers of composition.

Still, recognition of English music on the continent was rare and capricious. Englishmen wrote church music for the stage, stage music for the church, organ music for the orchestra, and, as far as we had any orchestral ideas at all, orchestral music for the organ. The one famous English composer who could be understood on the continent as saying intelligible things in fit terms, was Sullivan, with his Savoy operas. And his serious colleagues and critics urged him "with owl's solemnity to produce no more light masterpieces but to go on with his serious and luscious Golden Legends and Martyrs of Antioch and generally to consummate the final merging of English music into "The Lost Chord." We may thankfully hope that that chord is now lost for ever; but the Savoy operas live, and might, without delay to their popularity, have risen to the position of great music if Sullivan had had enough steadfast love of music to finish those parts of his work to which the public did not listen; if for example, he had provided his operas with better orchestral introductions than the perfunctory pot-pourris of their favourite tunes which he calls overtures and which are quite as long as artistically-decent overtures would have been.

It is customary to explain the failure of all but the most recent British music by saying that the native art was crushed by the ponderous genius of Handel. It is a great pity that the united ponderosity of Handel and the middle-weight Mendelssohn could not avail to dam the output of oratorios by composers who might have become good song-writers or even acquired some knowledge of orchestration beyond that of choral accompaniment. The complaint of foreign domination is nonsense. No nation has had its music so long and so completely dominated by foreigners as

France; and French music has always remained exclusively French and has made thoroughly French artists of the foreigners who dominated it. The traces of foreign influence on English music have always been the echoes of individual phrases or mannerisms. While we have echoed, as the fashions change, Mendelssohn, Brahms and Debussy, we have learnt no technical lessons from them. Such mechanical echoes show no foreign domination, but are the best proof of an inveterate provincialism and the kind of ignorant and irritable independence that goes with it. Since music ceased to be an integral part of an Englishman's culture (about the time of William and Mary) our musicians, as a rule, began its serious study far too late. The language of music cannot be begun at the age of 19 like courses in law or medicine. Our universities have played a considerable part in shaping British musical destinies; but mighty Oxford treads on the tongue of the encyclopaedist who would pursue this topic.

11. MUSIC OF THE 20TH CENTURY

The 20th century inherited the last development of the 19th in the symphonic poems and operas of Richard Strauss (*q.v.*). Much acrid controversy at first raged around the details of his style which dashed through all the traffic regulations of classical part-writing. And nothing was easier than to identify all carping critics with Beckmesser and to accept humbly Strauss's own self-portrait as the hero of *Ein Heldenleben*. The elements that were sensational in Strauss's symphonic poems have become so familiar that we are in some danger of underestimating the importance of these works as real achievements of the problem in which Liszt failed; not the trivial problem of programme-music, but the vital problem of writing purely instrumental music on the Wagnerian time-scale. The power of composition in these works is unquestionable and remains eminent in their facile aftermath, the *Alpen-Sinfonie*, which, designed before the World War, appeared in 1915. But Strauss had eclipsed the fame of his symphonic works by his operas, which began to be important with *Salome* (1905), a setting of Oscar Wilde's play. Then came the long and fruitful partnership with Hugo von Hofmannsthal which is still in being, and has enabled poet and musician to prove the possibility of many different kinds of modern opera, Wagnerian and non-Wagnerian. The purity of the Straussian metal has been strongly alloyed with worldly wisdom in every phase of Strauss's career; in the period of the good boy of the conservatoire; in the romantic symphonic poet of *Tod und Verklärung*; in the timely musical adaptation of Wilde while he was still a new discovery on the German stage; in the seizing of the opportunity presented by Hofmannsthal's *Elektra* after its triumph as a play; and not least in the present phase of naïve melodiousness. Nevertheless *Die Frau ohne Schatten* is perhaps the most noble gesture in music since the World War. From the twilight of *fin-de-siècle* and recent erotic art and from its always selfish and sometimes abnormal sexual preoccupations, *Die Frau ohne Schatten* breaks away with a heroic plea for normal love and life, unassailable by any cavil that does not write itself down as ignoble, musically, Strauss's grandest and most grandly realised opportunity for beauty. As a theatrical spectacle it is a gorgeous pantomime, no more disturbed by its allegorical meaning than *Die Zauberflöte*, which it in some ways intentionally resembles. *Die ägyptische Helena* (1928) descends from this high level into all manner of cleverness in its stage-technique and of facility in its music.

Whatever has been gained in the 20th century music, Strauss presents an almost solitary example of mastery of movement. Elsewhere, neither in academic teaching nor in new musical developments does any sense of movement seem to be cultivated. The vast cosmic movement of Wagner is attempted in Bruckner's fashion, by composers who seem to think that huge dimensions can impress us as huge without any reference to human measurements. The best work of Sibelius shows a true sense of cosmic movement and a real freedom and economy in the forms by which this is expressed. With other modern composers the most curious musical inhibition is that which makes them continue to write

sonata works in the four classical movements with a rigidity unknown to Mozart, Haydn and Beethoven, though the modern matter has no more connection with sonata form than Wagnerian music-drama has with the da capo aria.

This lack of necessity in form is nowhere more conspicuous than in the whole work of Max Reger who is usually regarded as the Brahms of the 20th century. His untimely death happened when he was evidently about to change his style. He was a pupil of the most mechanically-systematized musical scholar of recent times, Hugo Riemann; and anyone who has groaned in spirit at the sight of one of Riemann's instructive editions of a piece of classical music may easily recognise in Reger the traces of Riemann's teaching. Every external feature of the classical art-forms is present without any trace of the classical reasons for it. Everything has been worked out from one detail to the next as if it had been plotted on squared paper ready marked by someone else with points of reference.

Whatever is to be learnt from Reger, it is not the meaning of classical art-forms. And much is to be learnt from Reger. His texture is inevitably thick, for its systematic completeness vetoes the suggestiveness of the highest art. But it is astonishingly sonorous, and its numerous notes are the fewest and most effective for its ponderous purpose. Every instrument is treated according to its natural technique; and while the player who claims that he can read Reger at sight is probably mendacious, he will enjoy his instrument the better for playing Reger well. The fundamental reality of Reger's is that he is not only a sincere artist but a consummate rhetorician. But this age must be very ill-informed as to the foundations of music if it elects Reger as its Brahms.

There is at present no Brahms; the 20th century must enlarge its musical experience before another renaissance of classical form can either be expected or recognized when it comes. It might be as likely to come from Russia as anywhere; the gigantic geniality of Glazounov is still with us, active in the composition of brilliant classical and symphonic polyphony, and generously stimulating to younger composers; and the efforts of young artists to find out things for themselves may lead to something more fundamental than revolt against academicism or than the still narrower academicisms that young revolutionaries are apt to set up among themselves.

Scriabin's later harmonic system has been touched upon in the article HARMONY, Section 7. At this point we may sum up the lessons of three harmonic revolutions distributed over five centuries of musical history in the generalization that whenever a composer becomes permanently pre-occupied with harmonic ideas his power of composition is in great danger of paralysis. The reason for this lies deeper than the nature of music itself. Similar tendencies in literature reduce the power of sentence-building to that of the first Ollendorffian exercises. Scriabin's Chopinesque but stiff style of composition was fortunately well mastered by him before he doomed himself to discover that the harping on any chord however strange and novel in the long run only produces the effect of a sophisticated dominant seventh. Before his style receded into its theosophical fastnesses Scriabin had achieved in his fifth sonata and in his orchestral *Poème d'Extase* (both inspired by a literary poem from his own pen) works of powerful impulse that could not have been written on earlier harmonic and rhythmic resources.

The chances of producing permanently living work are heavily weighted against the composer who confines his art to things which he alone can understand. The Russian Ballet gives abundant vital occasion for music as long as it deals intelligently with drama, fairy-tale, fable and life; and the young Stravinsky found in it inspiration for music that remains intelligible apart from the spectacle. In *Petrouchka* he still produces rhythms and tones that enhance the moods of a fascinating pantomime; but the concert-goers who profess to enjoy it without ever seeing the ballet show themselves to be of the tribe who will gaze "as ducks that die in tempests" at anything they are told to admire.

Self-deception and dry-rot set in when the designers as well as the composers of the ballet retire into the arbitrary kingdom

of abstractions which they call symbolic and which common sense calls nonsense. Opinions will never unite as to where the line should be drawn; but the 20th century will differ from all other periods of human history if a large percentage of its most precious nonsense does not vanish into the limbo of mere nonsense before its generation becomes middle-aged.

The art of Debussy made its mark without any such artifices. Some aspects of it are discussed in HARMONY, Section 8; but Debussy would have indignantly repudiated the resolving of his whole-tone scale as a six-part polyphonic chord, though he himself cannot resist the impulse to resolve it on to a pentatonic scale which is itself constructable as a chord. Debussy's propagandists believed him to be more closely confined to his special system than was the case. Eclecticism was always breaking in without any damage to the aesthetic coherence of the style. It is probable that Debussy's art, discreetly anthologized will remain vital when the work of the more voluminous and hard-headed Ravel will have become no more distinguishable from an echo than Sterndale Bennett is from the echo of Mendelssohn. Independent origin does not settle such questions. Cyril Scott has been called the English Debussy, but he began to form his style before Debussy was known.

One of the eternal questions in aesthetics is the proportion of means to ends. The World War has tragically dictated to all artists a preference of the study of reduced rather than of increased resources; yet performances on the scale of our own Handel Festivals in the Crystal Palace still continue to take place, though the music for an organization of even half that size has never yet been composed. Here, then, is material for a real and strenuous aesthetic discipline; and the zeal of Mengelberg has created in Holland a great vogue for the vast works in which Mahler, while writing for existing conditions, sets himself the task of pioneer-work in the aesthetic and technical principles of music designed for 1,000 performers and upwards. Taste is of secondary importance in such an enterprise, and Mahler is likely to be underrated in countries where naïve sentimentality and boyish grandiosity encounter the inhibitions of a musical culture that thinks itself wiser. Mahler was one of the greatest orchestral and opera conductors that ever lived. On the total value of his compositions tastes may agree to differ, but this century has seen no more strenuous idealist. The main stream of music still flows within the Wagner-Strauss limits and seldom requires 150 instrumental players. Arnold Schönberg's "Gurrelieder" (a large song-cycle for chorus and soli, the great success of which is held to be a hindrance to the spread of his later and more revolutionary gospel) requires an extraordinary orchestra; but the polyphony that requires 50 staves for its notation implies detail rather than mass.

The performance of Elgar's *Dream of Gerontius* at Düsseldorf in 1902, its enthusiastic reception there, and finally the generous speech of Richard Strauss then delivered in its honour, inaugurated the recognition of modern English music on the continent and gave English critics and audiences a not unneeded lesson after their lukewarm reception of it at its inadequate first performance at Birmingham. Elgar's rich and subtle orchestration is not more remarkable than the wealth of his invention of themes. His contemporary, Bantock, is a prolific composer in a style far easier but not less personal and sincere, in which the influence of Strauss and the schematic purity of Rimsky-Korsakov's orchestration may be traced by their technical results but not by mannerisms. Nowhere in Europe is there a more radiant source of musical health.

In Italy the masterful personality of Boito (1842-1918) developed in the 19th century but his musical ideas anticipate the 20th. He wrote brilliant libretti to Verdi's last works and those of younger composers and achieved extraordinary musical fame by two operas, *Mefistofele* and the posthumous *Nerone*. These have taken their place among the historic documents of musical Italy on the strength of less actual musical content than any other operas in existence. Their aristocratic refinement and *flair* for atmosphere is unquestionable. Very different is the full-blooded efficiency of Puccini (1858-1924) in whose hands Italian

opera advanced in the estimation of a public that was in all countries becoming too experienced in music to be satisfied with perfunctory orchestration and histrionic convention. The razor-edge intellect of the great pianoforte artist Busoni (1866-1924) achieved important results in compositions for the pianoforte, the orchestra and the stage, in spite of the energy he spent in demonstrating how much more cleverly the classics would have been written if they had possessed his advantages. If Casals (*q.v.*) gets his way, the musical awakening of Spain will soon be a leading feature in the history of the modern art.

In England there are encouraging signs that musicians are beginning to think for themselves without confusing between independence of academic tradition and independence of truth. Gustav Holst's interest in oriental subjects is (like Bantock's) no whim for *chinoiserie*s but a true expression of the nostalgia of the West for the East. His *Hymn of Jesus* is worthy of its awe-inspiring Byzantine eucharistic text. Vaughan Williams, with less of Holst's wide and clear-sighted exploration of pre-harmonic regions, composes with consistent nobility on a large scale and in a style that it would be an impertinence to try to trace to its various historic origins.

Thus the work of doctrinaires is not all that is happening in modern music; and, in any case, music is in the happy position of existing, like architecture, on practical terms which forbid mere lunacy to flourish unchecked. A large proportion of modern musical developments have been tested by enthusiastic and capable public performers almost before the ink of the manuscript was dry. Immediately before the World War, Rutland Boughton's small-scale Glastonbury festivals of music-drama were a stimulus of incalculable importance in the history of modern British opera; and at the present day on the continent the younger composers of chamber-music have the help of knight-errants in the masterly Amar Quartet which, with Paul Hindemith as viola and his brother as violoncello, spare no pains to secure for the most difficult experiments (such as the quarter-tone works of Haba) a perfect performance. Hindemith himself is one of the boldest and most masterly experimenters, if indeed, he is not the master of them all. It is very significant that his vocal writing, which seems to contradict all previous orthodoxies, stays uncommonly firmly in the vocal memory once it is mastered; whereas many otiose modulations in the Lisztian music of the seventies, such as the part-songs of Cornelius, sink in pitch however much choirs may practice them. The young masters who sternly renounce romance make a romantic gesture in the very act.

Much has been said as to the fructifying or deleterious influence of jazz. The highest class of jazz-band is undoubtedly composed of sensitive artists; but the conductor of a symphony orchestra in a musically not metropolitan town will, if he engages for a symphony concert the gentleman who handles the percussion apparatus of the best local jazz-band, discover that that artist's methods are entirely extemporaneous, and that, except with a drumstick, he has never clashed the cymbals otherwise than flat on to the top of the big drum, and never counted rests in his life. Ordinary jazz-music distributes its rhythmic surprises over the most imperturbable eight-bar ambling trot that ever lulled the rhythmic sense to sleep. Most drugs that begin with a stimulating action end as narcotics.

12. PROBLEMS OF THE FUTURE

The explorers of new musical intervals are hampered by having to deal with classical keyboards and other practical limitations. Perhaps they would do well to investigate Miss Schlesinger's pianoforte-tuning, already mentioned in connection with Greek music; for, whether it be Greek or not, it is scientific and therefore more natural than most of the experiments that composers have yet tried in the way of quarter-tones. But new instruments cannot be so readily produced as in the 18th century. Harpsichords and early pianofortes were *made*; but pianofortes are now *manufactured*. Emmanuel Moór's duplex-coupler pianoforte enormously extends the resources of the instrument without compelling the player to unlearn the classical technique. But its progress is impeded by the commercial difficulty of promoting an

improvement that cannot be added as an extra apparatus to existing and standardized pianofortes, and its reputation is damaged by the tendency to expound it as a device that makes existing feats of technique nugatory, a policy that infuriates the pianoforte virtuoso and ignores the great new possibilities of the invention.

Resonators have been invented for many instruments. The claim that by such devices one violin can sound like sixteen ignores the real effect of the choral multiplication of instruments, which consists far more essentially of a change in quality of tone than of a mere increase of volume. No resonators, phonograph discs or loud speakers for wireless transmitters will ever replace the quality of sounds that combine in the ear from the various directions of their dispersed orchestral sources. The listener need only put his hands around his ears while listening to an orchestra in a concert-room, and he will realise that a "gramophone effect" is little more than the result of cutting off the waves that reach the ear from other than the frontal direction.

The main importance of "wireless" lies in the fact that it appeals *viva voce* to millions without producing the phenomena of crowd psychology. Here and there it leads to a revived interest in intimate early pianoforte music that would never satisfy modern ears in the concert-room, and a new fact in musical aesthetics is the beauty of microphonically-magnified tones of very faint instruments such as the clavichord. Wireless is undoubtedly increasing the number of fireside music-lovers; but it needs careful administration to prevent it from a tendency to cut off orchestral music at the source; for many of the new music-lovers prefer tinned music at the fireside to live music in the concert-room. It is urgently necessary that the wealthy supporters of music should be made to see the folly of the notion that good music should be expected to pay its way commercially.

Wireless music may prove less subversive than another revolution by means of the microscopic study of phonographic records. There is nothing to prevent the eventual production of music directly in terms of the track of the phonograph-needle. That is to say, the composer, untrammelled by the technique of instruments, will prescribe all producible timbres in whatever pitches and rhythms he pleases, and will have no more direct co-operation with the craftsman who models the phonographic wave-lines than the violinist may with Stradivarius. The crudest beginnings of this new method of composition will be enormously important; but its highest development will still leave the handling of human voices and instruments supreme as the infinite source of inspired music. (D. F. T.)

THE UNITED STATES

The musical history of America does not begin, properly speaking, until the 19th century. To be sure, songs were sung and instruments played upon during the 17th and 18th centuries; but such performances were the casual pastime of the Southern and Middle Atlantic gentry, rather than the expression of a national art. New England, rigidly Puritan, sang psalm tunes, and but few of those. In 1737 Francis Hopkinson, of Philadelphia, published his first song, "My Days Have Been So Wondrous Free"—the first American secular composition.

Colonists, being recruited from the ranks of adventurers, farmers, traders and refugees, had neither the time nor the inclination to cultivate the arts. They were too completely preoccupied with life's exigencies to bother about its adornments. It is hardly surprising, therefore, that music played a negligible rôle in American civilization until such time as the pioneers had conquered their natural and political enemies, and the 13 Colonies, finally emancipated and achieving a measure of peace and economic security, had settled down to the business of becoming a nation. Repeating summarily the musical history of Europe, America's early musical contributions were religious and popular; the former through the hymns of Lowell Mason (1792–1872); the latter through the now-forgotten but once ubiquitous salon pieces of Louis Moreau Gottschalk (1829–69), and the songs of Stephen Foster (1826–64).

To realize what a recent growth American music is, it is necessary only to reflect that such living musicians as Arthur Foote (b. 1853), George W. Chadwick (b. 1854), Elgar Stillman Kelley (b. 1857) and Frank Van der Stucken (b. 1858) were virtually pioneers in musical composition in their native land, their only predecessors of any considerable note being Benjamin J. Lang (1837–1909), John Knowles Paine (1839–1906) and Dudley Buck (1839–1909). Other members of this group were Ethelbert Nevin (1862–1901), Horatio Parker (1863–1919) and Edward MacDowell (1861–1908), the latter being the most gifted composer that America has yet produced. To the same epoch belong also Reginald de Koven (1859–1920) and Victor Herbert (b. Dublin, 1859; came to America 1886; d. 1924), both of whom achieved international fame as composers of light opera.

All these composers, Foote alone excepted, were German-trained, the lack of adequate instruction at home rendering European study almost imperative. The virtual impossibility of obtaining a thorough musical training in America, thus obliging the student to spend his formative artistic years in a foreign country, has been a great handicap to the American composer. Coupled with the want of any authentic background of native folk music, it has been the cause of the slowness of American music to exhibit any distinctive national characteristics. One suggested solution has been to turn for musical inspiration to the American Indian. Of this method Charles Wakefield Cadman (b. 1881) and Arthur Farwell (b. 1872) are enthusiastic champions. Another, of which Henry F. Gilbert (1868–1928) was the best-known advocate, was the exploitation of American negro spirituals and slave songs. In recent years, the popularity of American jazz has suggested this as a third possible foundation for a national musical idiom. In this field George Gershwin (b. 1898) has been most successful.

Other contemporary American composers, whose work follows no definite nationalistic programme, are Howard Brockway (b. 1870), Frederick Converse (b. 1871), Edward Burlingame Hill (b. 1872), Daniel Gregory Mason (b. 1873), Henry Hadley (b. 1874), John Alden Carpenter (b. 1876), John Powell (b. 1882), Emerson Whithorne (b. 1884) and Deems Taylor (b. 1885). The untimely death of Charles T. Griffes (1884–1920) cost America a brilliant talent. To the present-day group belong also Charles Martin Loeffler (b. 1867) and Ernest Bloch (b. 1880), who, though born respectively in Alsace and Switzerland, should be considered American composers.

In the interpretative field of music America has been particularly prolific in famous opera singers. These include—to name a few—Minnie Hauk, David Bispham, Sybil Sanderson, Lillian Nordica, Edyth Walker, Emma Eames, Clarence Whitehill and

Geraldine Farrar. Opera itself, on the other hand, has never been a successful form of American musical expression, principally because the scarcity of permanent companies made it impossible for the would-be operatic composer to gain practical experience.

The growth of symphony orchestras has been extraordinarily rapid. Beginning with the Philharmonic Society of New York (founded in 1842), they have increased in number until in 1927 the country contained nearly 50 of them, the more important being, as a group, without a peer in the world. Pioneers in this work were Leopold Damrosch (1832-85) and Theodore Thomas (1835-1905). The custom of giving concerts especially for children is universal among the larger orchestras, and has had much to do with the rapid growth of musical appreciation in America. An extension of this movement, inaugurated in 1928 by Walter Johannes Damrosch (b. 1862), was the broadcasting of an entire series of educational concerts to schools and colleges throughout the country as far west as the Rocky mountains. Walter Damrosch's greatest services to American music were rendered in connection with the New York Symphony Orchestra and as a conductor of opera, but he was himself a distinguished composer.

In 1928 the future of music in America looked bright. Largely on account of the World War, which drove scores of Europe's finest interpretative artists to migrate to America, the concert centre of the world was then in New York. The country's wealth has made possible the expenditure of lavish sums upon the development of musical resources. American orchestras are the finest to be heard. The Metropolitan Opera Company of New York, and the Chicago Civic Opera Company, offer productions that, in scenic elaborateness and vocal resources, challenge comparison. American conservatories have vastly increased in number and immeasurably improved in quality. Two of them, the Curtis Institute of Music in Philadelphia and the Juilliard Musical Foundation in New York, are richly endowed and offer instruction at the hands of world-famous masters.

Interest in music is wide-spread, its growth augmented by such factors as the broadcasting of symphony concerts, the excellent orchestras of the larger motion picture theatres, and the extensive use of mechanical reproducing devices. The American musician can at last approximate the opportunities for technical training, practical experience and intelligent appreciation that have so long been enjoyed by his European colleagues. A corresponding growth in his self-respect, individuality and artistic stature is virtually inevitable.

MUSIC, TEACHING OF. As there are three possible parties to any musical transaction, the composer or maker of the music, the performer or reproducer of it, and the listener or appraiser of it, it follows that the art of teaching, as applied to music, naturally falls into three categories: (1) the teaching of the nature of music itself; (2) the teaching of singing or playing some instrument or of conducting; and (3) the teaching of the appreciation of music. This last manifestly should be the same thing as (1) but without the creative incentive.

The teacher and the self-taught in all three categories have obviously one supreme obligation in common, namely, to train the ear with a serviceable exactitude to detect musical tones and to relate them instantaneously with each other into sensible and delightful order, whether together as chords, or in succession as melody, or in a succession of chords, or a combination of melodies, as in harmony and counterpoint.

Teachers of singing, and of playing, have the added task of inducing their pupils to hear the whole, of which what they are singing or playing is a contributory part—to see the whole building of which they themselves are an essential brick. Consideration of the art of teaching as applied to the act of singing and playing lies beyond the present purpose. But it may be noted with satis-

faction that in the present day a steadily increasing attention is being given to the crucial matter of ear training. Aural exercises and ear tests are now common in practical examinations, but have yet to become adequate and universal. It is astonishing that they have been so neglected that to-day Doctors of Music can still probably be found who cannot with ease give an instant and accurate account of even a few simple chords as they are played, but would "rather see that done on paper."

Incidentally the teaching of the art of reading music offers problems and interests of its own to teacher and taught alike. It is with some quite good musicians a life-long problem to learn to correlate the efforts of eye and ear and voice (in singing) or fingers (in playing) into one well-synchronised act. In the study of a field of literature, or poetry, through the medium of reading it would be a heavy handicap to any lover of fine thought to have to struggle with the mere problems of reading as he went along, and in music there is no reasonable hope of an effectual national culture without a recognition of the proved need and possibility of teaching small children to read music before they leave school.

At the present day it seems quite exceptional, either in a school or in a place of worship where singing is expected, to find even the melody of the tune supplied to the scholars or the congregations. Indeed it seems probable that if by some magic wand all the "Words only" editions of hymn books and song books in the whole country could be transformed into "Melody editions" for twenty years, a standing, but apparently needless, difficulty would be automatically removed. The present writer met a young airman during the recent war, who, being driven to find relief from war in trying to make melody for himself, had actually to invent a queer and original notation of his own by the use of numerals in which to write down his melodies.

It is interesting here to note that the thousand-year-old Sol-Fa syllables, by which notes are still to this day set down and learnt, were originally the result of an effort by Guido, a monk of Arezzo, to teach music-reading by associating the first syllable of each line of a certain hymn to St. John the Baptist with one of the six degrees of the hexachord. Just as the monastic schools of Europe contributed to the teaching of music much that was based on immediate experience, so also have our own choir schools, attached to the cathedrals, collegiate chapels, and to some churches. Nevertheless, it seems clear that the great hope of a broad basis of music teaching and of general musical culture lies in the ordinary schools of the country, and to some extent also in that choral singing which is so wholesomely associated with the act of worship.

Apart altogether from teaching performance, or mere reading, the art of teaching as applied to music itself seems to have lingered, up to the present, in what are naturally first stages. Just as the first stage of teaching a small child its mother-tongue is naturally that of imitative repetition, so in music the communication of the art from mind to mind has, broadly speaking, continued to dwell, up to the present, in that region where imitation of the practice of admirable composers is urged upon the learner, or where, at the best, the composer's customs and ways are reduced to certain bye-laws (necessarily with many exceptions) treated as laws, or even as high principles, and invested with an authority often pathetically falsified by events. To take a notorious example, the excellent bye-law against the writing of so-called consecutive fifths in similar motion between any two parts (say a tenor and a bass part) is laid down in almost all text-books, and yet it is cautiously set aside by many, and by others freely flouted, obviously not for caprice, but faithfully.

MODERN OUTLOOK

Still, in spite of the conspicuous absence of an accepted way of teaching music on any logical and generally comprehensible basis—an absence, that is, of any *corpus* of teaching based on broad principles which commend themselves to the common sense of all men—good sectional teaching has been evolved, either by following the general course of musical history, or by following merely the particular practice of one period (such as that of the 16th century, for so-called Strict Counterpoint) and sometimes

even of one towering, dominating mind (such as that of Bach, for Fugal Counterpoint). There has consequently been a voluminous and careful output of useful treatises which have done much to help the student, if also often to puzzle him as to the why and wherefore of their inhibitions. These treatises usually still divide musical study into what seem to be arbitrary partitions.

Our leading colleges and academies of music, as well as our university musical faculties, have, up to the present, prescribed courses, both of teaching and of examination in music, broadly under the following six sectional heads:—harmony; counterpoint; fugue and fugal counterpoint; musical form; musical history; composition. The gaps, the overlappings, and the confusions of such a system are glaring, and increasingly disconcerting to teachers and students alike.

To name but one gap, it will be noticed that melody is not itself a fixed subject of tuition at all, though a moment's thought would probably cause 999 out of any 1,000 teachers to admit gladly that if their pupils in all the other sections came to them after a special course in melody, and in the mastery of melodic sense, construction and analysis, their powers to cope with and co-ordinate the rest of their musical studies—including Harmony, Counterpoint, Fugue, Form, and the whole range of Composition—would be measurelessly enhanced.

Again, to name but one of the many overlappings, harmony and counterpoint are practically and admittedly inseparable. It is as impossible to detach harmony from counterpoint as it is impossible to do the simplest cross-word puzzle without thinking both vertically and horizontally. Yet they are definitely divorced for study, though all good teachers help their pupils to the habit of unified thinking.

Finally, to name but one confusion, counterpoint may still be taught by one good teacher (following perhaps Rockstro and R. O. Morris) as a method of acquiring understanding of sixteenth-century musical style, and by another equally good teacher (following perhaps Albrechtsberger via Macfarren) as a mere artificial method of restricted mental exercises under temporary by-laws. As a result, perhaps in the same music school or university, a student may be counselled in his counterpoint exercises to write gracious melody, mostly consisting of steps of a second and leaps of a perfect fourth or fifth (not because they accord with musical principles, but because Palestrina wrote in that way), and in another room he may be told mainly to restrict himself to one chord in a bar and to write a given number of notes to that chord in each exercise, and he may be allowed to leap diminished fifths and major sixths in the process as he pleases, so long as the one chord is maintained.

Obvious as are all three kinds of drawbacks, present-day teachers of music can at least claim the merit of sending students to consult and emulate the personal perfections of the composers who seem most trustworthy and admirable. But it is clear that we await a new and simpler teaching, more impersonal, more tolerant yet more precise, based on high common-sense.

Three notable factors in to-day's position (1928) as to the general teaching of music throughout the country may here be briefly noted, one of which is new. The first is that the mere technical difficulties of performing music (whether vocally or instrumentally) seem to musical aspirants so numerous and formidable as perpetually to side-track the essential work of the teacher. When a mother says "I wish my daughter to learn music" she naturally means her to learn to play or sing, and to that both time and cost are constantly devoted.

A second formidable factor in the position is the mere technical difficulty, still felt, of teaching music-reading and script. Curwen's excellent adaptation of the ancient solmization and the ingenious French Chev  method of using numerals have helped to ease the situation in schools. But until the books are in the schools and the acts of reading from, and writing on a music-stave can be taken by the children in their stride while they are daily making melody together and enjoying it with disciplined zest, it is hard to see improvement ahead.

The third and hopefully new factor, which may render the present article speedily obsolete, is the sudden vast increase in avail-

ability of every kind of good music, and consequently of musical stimulus and enjoyment, by means of wireless and the gramophone. (H. W. D.)

THE UNITED STATES

Music received slight attention in the days of the American colonists. For the improvement of church music, manuals of instruction in singing were prepared early in the 18th century by two Massachusetts ministers, the Rev. John Tufts and the Rev. Thomas Walter. These books and their successors provided the text material for the "singing schools" and "musical convocations" which for years represented the chief activity in music study.

The first well organized effort to provide a more complete musical education was the Boston Academy of Music founded by Lowell Mason in 1833. From about 1840 a considerable number of Americans went abroad to study music, chiefly in Germany. These pioneers, reinforced by many foreigners, were leaders in the marked advance of their profession, especially after the Civil War. Music education was recognized by instructors in music at Oberlin college from 1838 and at Harvard from 1862. The college music department and the independent music school were first exemplified by the foundation of Oberlin conservatory (1865) and the New England conservatory (Boston, 1867). Then followed the Cincinnati Conservatory of Music (1867), Chicago Musical college (1867), Peabody conservatory (1868), College of Music in Cincinnati (1878) and the American conservatory (Chicago, 1886).

The most important music schools have developed along two general lines, either as independent music schools or as college or university departments. In the former the graduate receives a degree or diploma; in the latter music study is credited toward an academic or musical degree. Further additions to the list include the Yale School of Music, University of Kansas, University of Michigan, Vassar, Wellesley and Smith colleges, Combs conservatory (Philadelphia), Northwestern university, Syracuse university, Columbia School of Music (Chicago), Bush conservatory (Chicago), Newcomb college, Detroit Conservatory of Music, MacPhail School of Music (Minneapolis), Cornish school (Seattle), Louisville conservatory, Pittsburgh Musical Institute, Horner Institute (Kansas City, Mo.) and Cleveland Institute.

Four music schools have special endowments. The oldest was founded in 1904 as the Institute of Musical Art of New York; since 1926 it has been called The Institute of Musical Art of the Juilliard School of Music. The bequest of Augustus D. Juilliard (1919) left some millions of dollars for the promotion of musical education and culture, and led to the founding of a music school in New York city (1924). It is now a graduate school for students of unusual talent, with the Institute of Musical Art and an extension department as under-graduate provisions. The Eastman School of Music (1919) at Rochester, N.Y., a department of the University of Rochester, has been endowed with \$12,000,000 by George Eastman. The Curtis Institute of Music in Philadelphia (1924) has been endowed with more than \$12,000,000 by Mrs. Edward W. Bok.

In 1908 Arthur L. Manchester prepared a report on music education in the United States for the Bureau of Education, dealing with schools and departments of music, not with public schools. The widely varying curricula quoted led the compiler to the conclusion that undue exaltation of the vocational aspects of music had led to the separation of music from general educational thought. An improved condition is shown by the 1928 report of the National Research Council of Music Education, which shows that 85% of colleges and universities now allow entrance credit for music, and 77.5% offer courses in music for credit toward a degree. The organization (1924) of the National Association of Schools of Music is also promoting a more satisfactory state of curricula and credits. Efforts have been made in some States to demand certain standards of attainment for the work of the private music teachers, who flourish in abundance, but State regulation is not yet common. Chief among the teachers' organizations is the Music Teachers National Association, founded in 1876 by Theodore Presser. Many State associations of music

teachers have functioned along similar lines.

Public school music implies the recognition of music education for everyone, as contrasted with its study as a speciality. It began with Lowell Mason's work in the Boston public schools in 1837, an example followed promptly in Buffalo, Pittsburgh, Louisville, Cincinnati, San Francisco and other communities. The textbooks were derived from those of the "singing schools." The first provided for public school use were by Lowell Mason and Charles Aiken. *The National Music Course* (Luther Whiting Mason, 1879) was the first of numerous courses providing systematically arranged vocal material for all public school grades. In 1885 the Bureau of Education reported 90 special music teachers in 247 communities. By 1914 the number of communities had risen to 622, of which only 15 had no special supervisor of music. This report indicates decided advances in the education of the music supervisor; the existence of 238 high school orchestras (evidently beginning at Richmond, Ind., under the direction of Will Earhart); the teaching of harmony, music history or appreciation in school; the accrediting of private music lessons outside school; and a higher standard of choral music. The Music Supervisors National Conference was organized in 1907; in 1928 its membership exceeded 5,000.

The literature of musical education has received important contributions in theory from George W. Chadwick, Hugh A. Clarke, Benjamin Cutter, Arthur Foote, Percy Goetschius, Walter R. Spalding, Adolf Weidig and Bernhard Ziehn; in history from Edward Dickinson, Louis C. Elson, Waldo S. Pratt and O. G. Sonneck; in aesthetics and appreciation by Charles H. Farnsworth, Clarence G. Hamilton and Daniel Gregory Mason; in musical education by Frank Damrosch, Carl E. Seashore and Archibald T. Davison; in public school music by Karl W. Gehrkens, T. P. Giddings, P. W. Dykema and Edward B. Birge.

Scholarship is evidenced by *The Musical Quarterly*. Of the magazines devoted to music teaching *The Etude*, *The Musician*, *The Musical Observer* and *Singing* are among the most popular. Regular publications of various associations provide a valuable aggregate of educational ideas. Reproducing instruments of player-piano and gramophone types have had considerable place in school-music teaching and offer large supplies of educational material. Organizations deserving mention are the American Guild of Organists (1896), The American Academy of Teachers of Singing (1922), the Associated Glee Clubs of America, the Intercollegiate Musical Council and the National Federation of Music Clubs. The Carnegie Foundation has financially encouraged educational efforts in music, including the church music school at Northwestern university.

The trend of organized music instruction is toward a curriculum which balances performance and general music learning. There is abundant interest in music study and great activity in all its departments. This reflects public as well as professional concern.

(C. N. B.)

MUSICAL-BOX. The modern musical-box is an elaboration of the elegant toy musical snuff-box in vogue during the 18th century. The notes or musical sounds are produced by the vibration of steel teeth or springs cut in a comb or flat plate of steel, reinforced by the harmonics generated in the solid steel back of the comb. The teeth are acted upon and musical vibrations produced by the revolution of a brass cylinder studded with projecting pins, which, as they move round, raise and release the proper teeth at due intervals according to the nature of the music. The revolving motion of the cylinder is effected by a spring and clockwork, and the rate is governed by a fly regulator.

MUSICAL COMEDY, a popular form of theatrical entertainment, developed almost exclusively by the English-speaking peoples.

Clearly it bears little relation to the classical *opera buffa* of Italy. For that had no spoken dialogue, its place being taken by *recitativo secco*, a formal and rhetorical delivery of the words, supported by the lightest accompaniment. Mozart's *Figaro* and Rossini's *Il Barbiere* are good examples of *opera buffa*. Nor has musical comedy any real connection with the German *Singspiel* although in this case spoken dialogue is used instead of *recitativo*

secco. In France the *Singspiel* developed into *opéra comique*. But the French comic opera was not necessarily comic, being so called merely to differentiate it from grand opera. But one may look to the *vaudeville*, which dates its popularity from the time of the French Revolution, as being a more direct ancestor of modern musical comedy. But the *vaudeville* was written in verse, and musical comedy employs lyrics only for musical setting, the play itself being carried on by spoken dialogue.

A much closer analogy is to be found in the French *opéra bouffe*, which it may be noted is not to be identified with the Italian *opera buffa*. In the former, spoken dialogue alternates with light music, and in the play itself there are generally topical or satirical allusions. From the *opéra bouffe* and *vaudeville* sprang the operetta; at first, as its name implies, a short opera of one act which was employed to lengthen the evening's entertainment. Gilbert and Sullivan practically founded their operas on the operetta and *opéra bouffe*, but, except at first, they cast them into two acts of sufficient length to fill the bill. On its formal side, the English ballad opera may be considered one of the models for musical comedy. The English ballad operas came into being as a protest against the Italian operas of the 18th century. The English works were even composed in the Italian manner, recitative taking the place of dialogue. But they did not have much success until Gay wrote *The Beggar's Opera*.

The genre of musical comedy, then, is in direct descent from the *opéra bouffe* and the *vaudeville* of the French, combined with our own ballad operas, and, as it is known in London and New York, is an expression of a love of boisterous and farcical humour rather than of the high comedy of the operetta. Its humour is broader, more farcical and more eccentric than anything to be found in light French or Viennese opera, and the student will find curious evidence of this in the change which French or Viennese light operas undergo when adapted to the British or American stage as musical comedies. André Messager's *Véronique*, for instance, was first performed in London by a French company (1903) as a light opera. When it was produced, shortly afterwards, in an English version, the comedy part of the florist was developed by Mr. George Graves into that of an eccentric low comedian. The same procedure has been followed in the case of the many Viennese operas by Oscar Straus, Leo Fall, Franz Lehár and others which in more recent years have enjoyed such popularity in England and America. The farce of musical comedy was added, this element being a relic of the old-fashioned Gaiety burlesque. Those burlesques were in themselves more in the nature of what afterwards came to be known as *revue* in London and New York than of the musical comedy of to-day, with its definite plot and sentimental scenes. But it was from the Gaiety burlesque that the Gaiety musical comedy developed, with its music written by Lionel Monckton, Howard Talbot, Ivan Caryll and others.

During recent years the popularity of musical comedy of the older kind has been rivalled by that of the more go-as-you-please type of entertainment known as *revue*. In Paris, where it had its origin, the *revue* had a special character of social satire and topical interest. As adapted to the requirements of English-speaking audiences the *revue* has been a much more miscellaneous affair, a mere *mélange* of songs, sketches, low comedy, ballets and pageants strung together haphazard, although frequently including a strong infusion of the satirical and topical elements and thus recalling its French ancestry. So far as the London stage was concerned George Grossmith, who had taken such a large part in the Gaiety musical comedies, was the first to adapt the *revue* from France.

Revue became more and more spectacular, and gradually the best of these entertainments included ballets and pageants of great beauty. In a sense, that type of *revue* was a throw-back to the masque. With the popularity of *revue*, "syncopated" or "jazz" music found its way to the stage from the variety halls. From *revue* it gradually crept into musical comedy, and the long continuance of the World War, which automatically put an end to the domination of the Viennese school of musical comedy or light opera, gave this newer musical fashion full scope.

In the United States there is a College Musical Comedy League, founded in 1927 and consisting of various university bodies, one of which, the Hasty Pudding Club, of Harvard university, dates back as far as 1795; others being the Mask and Wig Club of the University of Pennsylvania (1889), the Triangle Club of Princeton university (1893), the Haresfoot Club of the University of Wisconsin (1898), the Blackfriars of the University of Chicago (1904), and the Mimes of the University of Michigan Union (1906).

MUSICAL INSTRUMENTS, MECHANICAL. (See BARREL ORGAN; MUSICAL BOX; GRAMOPHONE; PLAYER PIANO; MUSIC FROM ELECTRIC OSCILLATIONS.)

MUSICAL NOTATION, a graphic method of representing sounds to the ear through the medium of the eye. It is probable that the earliest attempts at notation were made by the Hindus and Chinese, from whom the principle was transferred to Greece. The exact nature of the Greek notation is a subject of dispute, different explanations assigning 1680, 1620, 990, or 138 signs to their alphabetical method of delineation. To Boethius we owe the certainty that the Greek notation was not adopted by the Latins, although it is not certain whether he was the first to apply the 15 letters of the Roman alphabet to the scale of sounds included within the two octaves, or whether he was only the first to make record of that application.

Indications of a scheme of notation based, not on the alphabet, but on the use of dashes, hooks, curves, dots and strokes are found to exist as early as the 6th century, while specimens in illustration of this different method do not appear until the 8th. The origin of these signs, known as neumes (*neuma*, or nodes) (*q.v.*) is the full stop (*punctus*), the comma (*virga*), and the mound or undulating line (*clivus*), the first indicating a short sound, the second a long sound, and the third a group of two notes. The musical intervals were suggested by the distance of these signs from the words of the text. The variety of neumes employed at different times, and the fluctuations due to handwriting, have made them extremely difficult to decipher. In the 10th century a marked advance is shown by the use of a red line traced horizontally above the text to give the singer a fixed note (F=fa), thus helping him to approximate the intervals. To this was added a second line in yellow (for C=ut), and finally a staff arose from the further addition of two black lines over these.

A variety of experiments resulted in the assignment of the four-lined staff to sacred music and of the five-lined staff to secular music. The yellow and red colours were replaced by the use of the letters F and C (fa and ut) on the lines. This use of letters to indicate clef (*q.v.*) is forestalled in a manuscript of Guido of Arezzo's *Micrologus*, dating from the 12th century, in which is the famous hymn to St. John, printed with neumes on a staff of three lines (see GUIDO OF AREZZO and HEXACHORD). The use of letters for indicating clefs has survived to the present day, our clef signatures being modified forms of the letters C, F and G, which have passed through a multitude of shapes.

Before the 12th century there is no trace of a measured notation (*i.e.*, of a numerical time division separating the component parts of a piece of music). It was at the time of Franco of Cologne that measured music took its rise, together with the black notation in place of neumes, which disappeared altogether by the end of the 14th century. In the black notation, which led to the modern system, the square note with a tail (■) is the long sound; the square note without a tail (■) is the *breve*; and the lozenge shape (◆) is the *semibreve*. In a later development there were added the *double long* (■) and the minium (●). The *breve*, according to Franco of Cologne, was the unit of measure.

The development of a fixed time division was further continued by Philippe de Vitry. It has been noted with well-founded astonishment that at this period double time (*i.e.*, two to the bar) was unknown, but only triple time which was regarded as "perfect"—"because it hath its name from the Blessed Trinity which is pure and true perfection." Vitry championed the rights of imperfect time and invented signs to distinguish the two. The perfect circle ○ represented the perfect or triple time; the half circle (the

imperfect or double-time. This C has survived in modern notation to indicate four-time, which is twice double-time; when crossed C it means double-time. The method of dividing into perfect and imperfect was described as *prolation*. The addition of a point to the circle or semi-circle (⊙ ⊙) indicated major prolation; its absence, minor prolation. The substitution of white for black notation began with the first year of the 14th century and was fully established in the 15th century.

It has already been shown how the earlier form of alphabetical notation was gradually superseded by one based on the attempt to represent the relative height and depth of sounds graphically. The alphabetical nomenclature, however, became inextricably associated with the graphic system. The two conceptions reinforced each other; and from the hexachordal scale, endowed with the solmization of *ut, re, mi, fa, sol, la*—which was a device for identifying notes by their names when talked of, rather than by their positions when seen on a page of music—arose the use of what are now known as accidentals (*q.v.*).

Of these it may here be said that the flat had originated from the necessity of sinking the B of the scale in order to form a hexachord on the note F in such a way as to cause the semitone to fall in the right place—which in the case of all hexachords was between the third and fourth notes. This softened B was written in a rounded form thus: b (*rotundum*), while the original B remained square thus: B (*quadratum*). The original conception of the sharp (*q.v.*) was to cross or lattice the square B, by which it was shown that it was neither to be softened nor to remain unchanged. The flat, which originated in the 10th century, appears to have been of far earlier date than the sharp, the invention of which has been ascribed to Josquin Des Prés (1450–1521). The B-sharp was called B *cancellatum*, the cross being formed thus: ✕.

The use of key signatures constructed out of these signs of sharp and flat was of comparatively late introduction. The key signature states at the beginning of a piece of music the sharps and flats which it contains within the scale in which it is written. It is a device to avoid repeating the sign of sharp and flat with every fresh occasion of their occurring. The double bb and the double sharp x' are conventions of a much later date, called into existence by the demands of modern music, while the sign of the natural (b) is the outcome of the original B quadrature or square B. (See TONIC SOL-FA and CHEVÉ notations.)

PROPOSED NEW SYSTEMS OF NOTATION

As regards the many new systems of notation which have been proposed during recent times, it must be remembered that although the staff notation (as we call the system of two separate staves of five lines each) was originally invented at a time when the unequal temperament system of tuning prevailed (see TEMPERAMENT), yet this old notation developed and is now employed in conjunction with equal temperament, from which it can never really be dissociated. Hence, for practical purposes, and theoretical implications apart, the result is the same, whether we write G sharp or A flat, for instance. For while some musicians still refuse to accept equal temperament save as an unavoidable compromise and you find such declaring that they "never think of the keyboard" when composing, yet the notation which they are compelled to use has no means of showing any finer divisions than equal temperament affords. The existing notation is not capable, for instance, of showing the difference between the real natural major third of the horn and the major third of the tempered keyboard.

It is possible that a means of doing this may be devised in time. If so, it may perhaps follow the system adopted by Anselme Vinée in his *Principes du Système Musical et de l'Harmonie* (Hamellet, Paris, 1909), in which he applies various marks (tiny curves, dashes and crosses) to the notes of the staff notation to indicate these extremely small variations in pitch.

As music became more and more chromatic, the complexities of notation increased tremendously by the multiplication of signs for what was practically the same sound. Thus C sharp, D flat

and B double-sharp have three different signs, but, in equal temperament, only one sound. Hence, during the last quarter of a century or so, many attempts at a simplified form of notation have been made either by improving the old staff system or by the invention of an entirely new system.

H. Orsmund Anderton, a London composer, proposed, in his *Simplified Notation*, a new method of representing the chromatic signs called "accidentals" by substituting a line through the head of the note for the sharp or flat sign; thus D sharp and D flat

A Spanish pianist and composer, Manuel Guervós (1863-1902), invented a system by writing the two staves (pentagrams) now called treble and bass into one "decagrama." He replaced the F and G clef (see CLEF) by a C clef resting on his 6th line. A German musical theorist, Hermann Stephani, went further in the reduction of lines. In 1905 he invented a system of notation which was entirely confined to the treble stave, all the higher and lower sounds being indicated by various octave signs. This system he called *Einheitspartitur* (unit-score) and he published in it the overture to Schumann's *Manfred*.

The acceptance of atonal music naturally makes for a system which shall ignore the difference between C sharp and D flat, D sharp and E flat, etc., and one of the chief apostles of that music, Josef Matthias Hauer, has published works with a special kind of atonal notation (Goll, Vienna).

Walter Hampton Thelwall, a London civil engineer, from 1893 onwards gradually evolved a system known as the Thelwall system, which uses two staves of seven lines each, the two staves reading alike, and the system involving a complete acceptance of the dodecuple principle, which divides the octave into 12 equal parts. Thelwall adopted for these the Roman numerals I. to XII. and his thick middle line is always the note VII., i.e., middle C. In order still more to destroy that back-lying feeling of C major, he calls F sharp I. He repeats his seven-line stave for every octave, dotting in the upper staves as required, the octaves all being numbered—the bass octave 4, the tenor octave 5, the treble octave 6, and so on.

An Argentine musical theorist, Angelo Menchaca, invented a new system, an exposition of which was published in 1904 under the title of *Nuevo Sistema teorico grafico de la Musica*, by Pleyel, Lyon & Co., Buenos Aires. In this system the staff is dispensed with altogether and the sign  represents the sound *Sol*. This note sign is written (or printed) in various positions for the various notes; and short and long stems represent the high or low octaves. The length of a note is shown by a point. (A full explanation of the system may be seen in Dent's *Dictionary of Modern Music and Musicians*, 1924, p. 352.)

Ferruccio Busoni (1866-1924) invented a new notation and published Bach's *Chromatic Fantasia* in it (Breitkopf and Härtel). Jean Hautstont, a Belgian composer and theorist (b. Brussels, Dec. 13, 1867), devoted himself to the reform of musical notation, and invented his *Notation Autonome* (Paris, 1907), which he applied in his *Solfège* (Paris, 1913). The system is based on the classification of sounds according to their vibration numbers, taken in conjunction with the physiological development of the human ear. In 1921 a society for publishing music in this notation was formed in Brussels.

In 1915, the Russian composer, Nicolas Obukof (b. Moscow, 1892), produced a work published in a new notation which abolishes the sharp and the flat and thus avoids duplication of signs. He ascribes new names to the notes represented by the black keys of the keyboard, viz., *Lo, To, Ra, Tu, Bi*. These were also derived from the ancient hymn from which the other syllables were derived by Guido of Arezzo. His scale reads *Do, Lo* (C sharp), *Re, Te* (D sharp), *Mi, Fa, Ra* (F sharp), *Sol, Tu* (G sharp), *La, Bi* (A sharp), *Si*. For the ordinary diatonic notes he uses the usual signs. For the sharp he uses the sign X or .

The English composer, John H. Foulds, has used *tertia-tones* in his orchestral *Music-Pictures*, op. 33 (1913), and in parts of his

World Requiem, op. 60 (1923). He marks his two-thirds sharp-ened tone \sharp , and his two-thirds flattened tone \flat .

Ivan Wischegradsky, a Russian composer, who has written much music on the quarter-tone system, has used the following signs:

Ascending, one quarter-tone sharp, \sharp ; two quarter-tones sharp, $\sharp\sharp$; three quarter-tones sharp, $\sharp\sharp\sharp$; descending, one-quarter-tone flat, \flat ; two quarter-tones flat, $\flat\flat$; three quarter-tones flat, $\flat\flat\flat$.

Alois Haba, a Czech composer, who has quarter-tone pianos made for him by the firm of Foerster, at Georgswalde, in Bohemia, has written pianoforte pieces and also string quartets on the quarter-tone system. He uses the existing notation for the ordinary tones and semitones, and adds new signs like "accidentals" for the new quarter-tone notes. Thus C raised a quarter-tone is represented by \flat and C raised three quarter-tones by $\sharp\sharp$, D flattened a quarter-tone by \flat and D flattened three quarter-tones by $\flat\flat$.

But the best quarter-tone notation will not be one that is founded on the existing notation, which is already too complicated and over-burdened with signs; it will be one much simpler than the old. For our semitonal system we have 39 signs for but 12 sounds. A well-designed quarter-tone system will only need 24 signs for 24 sounds. According to Haba, the new system will give no fewer than 288 new intervals; and 253 new three-note chords, with an infinite number of 4-, 5-, and 6-note chords.

Reform must certainly take the way of simplification, and a new notation is long overdue. The great obstacle is, of course, the cost of replacing the immense amount of music already published in the existing notation.

MUSIC FROM ELECTRIC OSCILLATIONS. The mathematical theory of electric oscillations was given by Lord Kelvin so long ago as 1853, in a famous Paper in *The Philosophical Magazine* called "Transient Currents." Helmholtz had already shown that the conservation of energy required an electric discharge under certain conditions, even a flash of lightning, to be oscillatory. And the fact that the discharge from a leyden-jar or other condenser consisted of an alternating current was subsequently verified by Feddersen, who photographed the spark in a revolving mirror, and saw that the band to which it was spread out was beaded. The merit of Lord Kelvin's paper was that it recognized the two chief causes of the oscillation, the electrostatic capacity of the condenser, on the one hand, which may be likened to the storage of energy in a spring with elastic recoil, and what he called the electrodynamic capacity of the discharger, on the other, which may be likened to the momentum of a stream of water or other material. These two properties are essential to oscillations. They may be called elasticity and inertia or momentum.

Whatever may be the reason, electricity exhibits these two properties. An electric charge displays the one, an electric current the other. Every detail of the oscillations was worked out by Kelvin, considered as the free and dying out oscillations resulting from the running down of stored energy, on the analogy of a tuning-fork. But whereas the oscillations of matter are to be estimated at the rate of a hundred, or at most a few thousand, per second, the rate of electric oscillation, which is concerned not with matter but with the ether, is to be reckoned in millions a second. Consequently electric oscillations are far too rapid to affect the ear, unless they are rectified and made tractable by some

such device as Fleming's vacuum valve.

Of late it has become possible, by means of valves, to maintain the oscillations continuously, from any convenient source of power, and such oscillations are in common use for wireless telegraphy. When two such circuits are operating in the same neighbourhood, though independently, they produce interference phenomena or beats, corresponding to the difference in their rate of vibration; and then, if the circuits are not too different or far apart in their rate of vibration, the beats may be of audible frequency when they are rectified, and communicated to a telephone or loud-speaker. For instance if one oscillated at 1,000,000 a second, and the other at 999,000, the beats would be 1,000 a second, which corresponds to a note, say C₄, above the treble clef. Any variation in the capacity of one of the circuits, modifying its rate of vibration so as to bring the two nearer together, would lower the pitch of the beat-note, and might abolish it altogether if the two circuits were exactly in tune. The pitch of the beats can in fact be raised or lowered at will. The process of extracting beat-notes is often called "heterodyning," and is well known to wireless operators.

A young Russian, M. Leo Theremin, by constructing the circuits so that the condenser of one of them has an exposed part whose capacity can be varied by bringing the hand near it, found that he could control the pitch of the beat-note in a satisfactory manner by alternately approaching and withdrawing his hand, and that by another device he could vary the loudness by similarly moving the other hand. He thus had what might be called a musical instrument, in which electric oscillations were controlled both in pitch and in loudness by the movement of the two hands, and thus, after a good deal of practice, by skilfully waving his hands, he was able to perform serious music. The surprising thing about his achievement was, not the control of electric oscillations for sound production over an extensive range, but the accuracy with which many of the tones of instruments such as a violoncello or a cornet could be imitated, and the skill with which an essentially continuous series of vibrations could be so managed—by sliding along the scale quietly and then swelling out—as to give the impression of the discontinuous notes required for melody. Eminent musicians did not disdain to express admiration of the performance, and even to consider the possibilities of the instrument for orchestral purposes. (O. J. L.)

MUSIC PRINTING. Printed music originated soon after the invention of typography and the year 1465 is given as the earliest date of any record of its existence. At first the method was only used for printing the staves in red ink from a woodcut, the notes being written in by hand. Later the staves and notes were engraved separately on wood blocks and printed respectively in red and black. Then followed the practice of cutting both the staves and notes on one block for printing in black. There are no records of music being printed from separate characters before 1473 when a theological work by a German printer named Gerson was issued containing five notes of music evidently so printed. This may be regarded as the foundation of music printing.

In 1482 William Caxton, the first English printer, published a work entitled *Polychronicon*, in which there are a few notes of music, though apparently filled in to the printed stave lines by hand. Wynkyn de Worde, who succeeded Caxton, reprinted this work in 1495, introducing both the notes and stave lines by type characters, so that he must be given the credit of being the first English printer of music from moveable type. The *Mains Psalter* of 1490 contained type-printed music. In 1500 Ottaviano Petrucci, in Venice, produced music with the staves and notes printed from type by separate operations.

Thenceforward the system of printing the stave lines separately fell into disuse. Pierre Attaignat, in Paris (1529), was the first to print the words of songs under the notes. In 1530 music began to be printed in England with type similar to that used by Petrucci, and it was done in two printings, but in 1539 a London printer named Gough issued music from type characters with the staves and notes printed at one impression. In 1550 Richard Grafton printed in London the *Booke of Common Praier noted*, the musical part being executed in type with red stave lines.

From that time printing from type became general and by 1500 it had assumed the appearance of present day music.

Music printed from plates dates from 1525, when Pierre Hautin, a French engraver, cut punches for the notes and stamped them into metal plates, which were finished by engraving. This style of work became general in England and continued to hold the field until about 1710, when music printed from punched plates began to appear.

Lithographic music printing dates from 1799, being first applied by Senefelder, the inventor of lithography, who drew the music direct on stone, or on transfer paper.

FROM THE "POLYCHRONICON,"
PRINTED BY WYNKYN DE WORDE
SPECIMEN OF THE EARLI-
EST EXAMPLE OF TYPE-
PRINTED MUSIC

Typographical music printing recovered its position with the production of better music type by the English letter-founders and came largely into use for hymnals, song books, and other musical works for which large editions in a cheap form are required. The work of setting-up music type is however very tedious as the staves and notes have to be built up from a large number of small pieces. A fount may contain from 400 to 500 characters.

At the present day the bulk of music printing, at least for sheet music, orchestral parts, etc., is done by lithographic printing, the original plates being made partly by punching and partly by engraving on pewter.

The method of engraving starts with ruling the staves on the plate with a five-pointed rake-like tool, called a "score"; then the spacing between the notes (previously determined by marking-off the manuscript) is set out by a method called "pointing," which is done with a small compass. The character of the notes and their position on the stave are roughly indicated on the plate with a blunt steel point called a "marking pin." During the punching the plate is laid on a stone slab and the punches are held in contact with the plate whilst a smart blow is given with a steel mallet. A set of punches usually consists of 50 to 53 pieces as a rule. Only the heads of the notes are punched, the hooks, ties, etc., being finished by gravers and other engraving tools. All the usual signs are punched and the words of songs are filled in with letter punches. Photo-lithography has been largely used for reproducing out-of-print music, the plates of which have been destroyed. Collotype has been found very effective in reproducing old music in facsimile.

MUSK, the name originally given to a perfume obtained from the strong-smelling substance secreted in a gland by the musk-deer (*q.v.*), and hence applied to other animals, and also to plants, possessing a similar odour. The variety which appears in commerce is a secretion of the musk-deer; but the odour is also emitted by the musk-ox and musk-rat of India and Europe, by the musk-duck (*Biziura lobata*) of West Australia, the musk-shrew, the musk-beetle (*Calichroma moschata*), the alligator of Central America, and by several other animals.

To obtain the perfume from the musk-deer the animal is killed and the gland completely removed, and dried, either in the sun, on a hot stone, or by immersion in hot oil. It appears in commerce as "musk in pod," i.e., the glands are entire, or as "musk in grain," in which the perfume has been extracted from its receptacle. Three kinds are recognized: (1) Tongking, Chinese or Tibetan, imported from China, the most valued; (2) Assam or Nepal, less valuable; and (3) Karbardin or Russian (Siberian), imported from Central Asia by way of Russia, the least valuable and hardly admitting of adulteration. The Tongking musk is exported in small, gaudily decorated caddies with tin or lead linings, wherein the perfume is sealed down; it is usually sent to the merchant by parcel post.

Good musk is of a dark purplish colour, dry, smooth and unctu-

ous to the touch, and bitter in taste. It dissolves in boiling water to the extent of about one-half; alcohol takes up one-third of the substance, and ether and chloroform dissolve still less. A grain of musk will distinctly scent millions of cubic feet of air without any appreciable loss of weight, and its scent is not only more penetrating but more persistent than that of any other known substance. In addition to its odoriferous principle, it contains ammonia, cholesterin, fatty matter, a bitter resinous substance, and other animal principles. As a material in perfumery it is of the first importance, its powerful and enduring odour giving strength and permanency to the vegetable essences, so that it is an ingredient in many compounded perfumes.

Artificial musk is a synthetic product, having a similar odour to natural musk. It was obtained by Baur in 1888 by condensing toluene with isobutyl bromide in the presence of aluminium chloride, and nitrating the product. It is a symtrinitro- Ψ -butyl toluene. Many preparations have been made, and the odour seems to depend upon the symmetry of the three nitro groups.

Musk in botanical terminology is *Mimulus moschatus*. (See *MIMULUS*.) The musk-orchis is *Herminium Monorchis*; the musk-mallow, *Malva moschata*; the musk-melon, *Cucumis melo*; the musk-thistle, *Carduus nutans*.

MUSK-DEER (*Moschus moschiferus*), an aberrant deer, presenting many peculiar characteristics (see *DEER*). There are no antlers, but in lieu of such weapons the upper canine teeth of the male form projecting tusks. About 20 in. high at the shoulder, the musk-deer possesses long limbs, and there is a great development of the lateral pair of hoofs. The ears are large and the tail rudimentary. The greyish-brown hair is long, coarse, and brittle. This animal inhabits the forests of the Himalayas as far west as Gilgit, always at great elevations and preferring thickets of birch, juniper, and rhododendrons. It extends into Tibet, Siberia, and north-western China. In habits the musk-deer is solitary, shy, and nocturnal, but very active; it feeds on moss, grass, and leaves. The deer takes its name from the secretion of a sac, about the size of an orange, beneath the skin of the abdomen, opening in front of the preputial aperture. This contains a dark brown substance of the consistency of "moist gingerbread." It is only present in the male (see *MUSK*). There is an allied species (*M. sifanicus*) inhabiting Kansu, distinguished by its longer, black ears.

MUSKEGON (mŭs-kē'gŏn), a city of western Michigan, U.S.A., on Lake Michigan, at the mouth of the Muskegon river, which expands here into a lake (5 m. long by 1.5 m. wide); a port of entry and the county seat of Muskegon county. It is on Federal highway 31, and is served by the Grand Trunk, the Pennsylvania, the Pere Marquette and electric railways, and lake steamers. The population was 36,570 in 1920 (81% native white) and was estimated locally at over 46,000 in 1928. The 1928 estimate for Greater Muskegon (including Muskegon Heights, an industrial city of 9,514 in 1920, North Muskegon, a residential village, and other adjacent suburbs) was 64,000. Muskegon has a fine land-locked harbour, with traffic amounting to 389,132 tons in 1925, valued at \$26,930,550. It is the centre of a summer-resort region; the metropolis of a fine dairying, farming and fruit-growing district; and above all a modern industrial city, with over 200 manufacturing establishments, employing 16,000 workers, and producing an annual output valued at \$80,000,000. Among the leading products are automobile motors and castings, phonographs, bowling and billiard equipment, window-shade rollers, piston rings and laboratory-table equipment. The city's public parks cover 1,500 ac. and include 7 m. of lake front. The public schools have an endowment of \$3,000,000, given by Charles H. Hackley (1837-1905), a lumber king, and his wife. The assessed valuation of property for 1927 was \$62,220,631. Bank clearings for 1927 aggregated \$60,154,697. The city operates under a commissioner-manager form of government. A trading post was established here in 1812, and permanent settlement began in 1834. The first saw-mill was built in 1837. The town was laid out in 1849, was incorporated as a village in 1861, and chartered as a city in 1869. In 1870 the population was 6,002. The lumber industry reached its peak in 1887, with a cut of 700,000,000 bd.ft., and the population at that time was about 24,000. With the depletion of the forests,

the population dwindled. The renewed prosperity began about 1900. The name Muskegon is probably derived from a Chippewa word meaning "grassy bog."

MUSKET, the term generally applied to the fire-arm of the infantry soldier from about 1550 up to and even beyond the universal adoption of rifled small-arms about 1850-60. The word originally signified a male sparrowhawk (Italian *moschetto*, derived perhaps ultimately from Latin *musca*, a fly) and its application to the weapon may be explained by the practice of naming fire-arms after birds and beasts (cf. falcon, basilisk). The "musket" proper, introduced into the Spanish army by the duke of Alva, was much heavier and more powerful than the arquebus. Its bullet retained sufficient energy to stop a horse at 500 and 600 yards from the muzzle. A writer in 1598 (quoted *s.v.* in the *Oxford English Dictionary*) goes so far as to say that "One good musket may be accounted for two callivers." Unlike the arquebus, it was fired from a rest, which the "musketeer" stuck into the ground in front of him. But during the 17th century the musket in use was so far improved that the rest could be dispensed with (see *GUN*). The musket was a matchlock, weapons with other forms of lock being distinguished as wheel-locks, fire-locks, snaphances, etc., and soldiers were similarly distinguished as musketeers and fusiliers. On the disuse, about 1690-95, of this form of firing mechanism, the term "musket" was, in France at least, for a time discontinued in favour of "fusil," or flint-lock, which thenceforward reigned supreme up to the introduction of a practicable percussion lock about 1830-40. But the term "musket" survived the thing it originally represented, and was currently used for the fire-lock (and afterwards for the percussion weapon). To-day it is generally used for military fire-arms anterior to the modern rifle. The original meaning of the word *musketry* has remained almost unaltered since 1600; it signifies the fire of infantry small-arms (though for this "rifle-fire" is now a far more usual term), and in particular the technique of using them (see *INFANTRY* and *SMALL-ARMS*). A *musketoon* was a short, large-bore musket somewhat of the blunderbuss type, originally designed for the use of cavalry, but afterwards, in the 18th century, chiefly a domestic or coachman's weapon.

MUSKMELOON: see *MELON*.

MUSKOGEE (mŭs-kō'gē), a city of eastern Oklahoma, U.S.A., 130 m. E.N.E. of Oklahoma City, near the confluence of the Verdigris, the Grand, and the Arkansas rivers; county seat of Muskogee county. It is on Federal highways 64 and 73; has a well equipped airport (Hat Box Field) controlled by the United States Air Service; and is served by the Frisco, the Kansas, Oklahoma and Gulf, the Midland Valley, and the Missouri-Kansas-Texas railways. Pop. (1920) 30,277 (73% native white and 24% negroes), estimated locally at 40,000 in 1928. It is the seat of United States Veterans Bureau Hospital 90 and the Oklahoma School for the Blind, headquarters of the Indian Agency for the Five Civilized Tribes, and the home of the Oklahoma Free State Fair. At Bacone, 2 m. N.E., is Indian University (Baptist; 1884). Muskogee is the metropolis of a rich agricultural and oil-producing territory. It has large railway shops, yards, and offices; wholesale and jobbing houses; oil refineries, cotton gins and compresses, cottonseed-oil mills, etc. The factory output in 1925 was valued at \$8,414,715. Bank debits to individual accounts aggregated \$145,441,000 in 1926. The assessed valuation of property for 1927 was \$29,999,656. Muskogee was founded about 1870, and became the chief town of the Creek Nation and the administrative centre of the former Indian Territory. The first railway (the "Katy") reached it in 1872. In 1893 the Dawes Commission began to transform the tribal allotments into individual holdings. The city was chartered in 1898, and in 1900 it had a population of 4,154. By 1910 the population was 25,278, a sixfold increase in the decade. The managerial form of government was adopted in 1920.

MUSKOGIAN INDIANS. This group constituted one of the larger speech stocks of native North America, and was typical of and dominant in the South-eastern area of aboriginal culture, comprising the region from the Gulf of Mexico to Tennessee, and from the Carolinas to Louisiana. The Muskogian family com-

prised a series of divisions: 1, Apalachee; 2, Hitchiti, Apalachi-cola, etc.; 3, Alabama, Koasati, etc.; 4, Choctaw, Chickasaw, Mobile, Pensacola, etc.; 5, Tuskegee; 6, Cusabo, Yamasee and other tribes of the Georgia coast; 7, Miskogi proper. The latter formed the bulk of what was later the Creek confederacy, in which the Hitchiti and other groups were included. The Natchez and Taensa of the lower Mississippi seem to be a remote Muskogian off-shoot; the Calusa and other south Floridian tribes may be. Since the middle of the eighteenth century the historically important tribes have been the Choctaw, Chickasaw and Creek, plus a branch of the latter, the Seminole. With the non-Muskogian Cherokee, these make up the "five civilized tribes," which for three quarters of a century, until 1906, maintained quasi-autonomous governments in Indian territory (Oklahoma), where they had removed under the pressure of American settlement.

Ethnographically the Muskogian or South-eastern culture province included, besides the groups listed, the Chitimacha and Tunica of the lower Mississippi, the Iroquoian Cherokee, the Timucua of central Florida and, in the lower region of Georgia and Carolina, the Yuchi, the Algonkin Shawnee and various eastern Siouan tribes. All these groups were agricultural, planting maize, pumpkins, beans, cane-millet, tobacco, sometimes Jerusalem artichokes, and sunflowers. They gathered hickory nuts and wild fruits, hunted deer and, in the west, bison, and stored nut oil and bear fat. The settlements were straggling; the "town" contained a square, on which were public and religious buildings; "villages" were often outlying. The towns were autonomous and essentially constituted tribes. They united into confederacies, directed by councils; such confederacies might break up and recombine. The most successful, like those of the Creek and Choctaw, grew in population during the colonial period, largely through absorption of smaller or shattered groups. The tribes were divided into matrilineal, totemic clans; chieftainship and office were hereditary, probably in the lineage within the clan. The Natchez and some other groups had superimposed a peculiar class or caste system. Chiefs in these cases were carried in litters, enthroned on raised seats or in arbours, and accompanied in death by sacrificial followers. All the tribes were warlike and in chronic but shifting embroilment with others. They took scalps and slowly tortured prisoners to death in a frame or tied to a post in the town square. Often there was a distinction between civil and military chiefs; the towns entitled to offices of one or the other kind in a confederacy were known as peace and war, that is, white or red.

Economic life was undeveloped as compared with the fairly well organized socio-political institutions. Houses were of logs or poles, wattled, chinked or plastered with mud, the roof of thatch. Bark or thatch houses were also built. Exposed settlements were palisaded, or log forts erected. Pottery was unpainted, basketry of cane splints; simple weaving was done in bark fibres and bison hair, but the principal clothing besides mantles was breech clouts for men and apron skirts for women. Many tribes deformed their heads. There was little property, almost no treasure, and limited trade before the coming of the whites. Ritual was also simple. The most important ceremony was the busk or green-corn festival, a first-fruits and new-fire rite. Purification by emetics was one of the commonest religious observances. There was little that could be called art. Most tribes had a migration legend.

The Muskogian-South-eastern culture extended with variations north into the Ohio valley to the prehistoric Moundbuilders, and north-east to the tribes of Iroquois lineage; it was represented in pallid form among many of the Algonkin groups as far as New England and the Great lakes. The total Muskogian population was about 50,000. At the time of discovery, there may have been 7,000 Creeks (increased to 20,000 by 1832), 3,500 Chickasaw, 15,000 Choctaw, 5,000 Apalachee, perhaps 5,000 Mobile. The first three of these tribes survive in increased numbers, but much mixed with white and negro blood.

See J. Adair, *History of the American Indians*, 1775; W. Bartram, *Travels*, 1791; J. Swanton, *Bur. Am. Ethn. Bull.* 43, 1911; 73, 1922. (A. L. K.)

MUSK-OX, an Arctic American ruminant of the family Bovidae (*q.v.*), representing a genus and sub-family by itself.

The musk-ox (*Ovibos moschatus*) is in some respects intermediate between the sheep and goats on the one hand and the oxen on the other, but is probably more nearly allied to the former than to the latter. The musky odour from which the animal takes its name is not due to the secretion of a gland.

In height a bull musk-ox stands about 5ft. at the shoulder. The head is large and broad. The horns in old males have broad

BY COURTESY OF THE NEW YORK ZOOLOGICAL SOCIETY

THE MUSK-OX OF ARCTIC AMERICA

bases, meeting in the middle line, and covering the brow and crown of the head. They are directed at first downwards by the side of the face, and then turn upwards and forwards, ending in the same plane as the eye. In females and young males the horns are smaller, and their bases separated by a space. The ears are small, and nearly concealed in the hair. The space between the nostrils and the upper lip is covered with short hair; the rest of the animal is covered with long brown hair, thick, matted and curly on the shoulders, but elsewhere straight and hanging down, concealing the short tail. There is also a thick woolly under-fur, shed in summer in blanket-like masses. The limbs are stout and short, terminating in unsymmetrical hoofs, the external being rounded, the internal pointed, and the sole in part hairy.

Musk-oxen are confined to the northern parts of North America; they range over the "barren grounds" between lat. 64° and the shores of the Arctic sea. Northwards and eastwards they extend through the Parry islands and Grinnell Land to north Greenland. The Greenland animal is distinguished by white hair on the forehead. Musk-oxen ranged during the Pleistocene period over northern Siberia and the plains of Germany and France. They have also been found in Pleistocene gravels in England. They are gregarious, assembling in herds of 20 or 30 head, in which there are seldom more than two or three full-grown males; they run with considerable speed, but when attacked normally form a circle with the younger animals in the centre. Musk-oxen feed chiefly on grass. The female brings forth one young in the end of May or beginning of June, after a gestation of nine months. The peculiar musky odour can be perceived from a distance of 100 yards. According to Stefánsson (*The Friendly Arctic*, 1921), they are admirably suited for domestication. The flesh is excellent, the milk equal to that of the domestic cow and the wool of considerable value.

MUSK-RAT or MUSQUASH, large North American rat-like rodent *Fiber zibethicus*, belonging to the mouse-tribe (*Muridae*). Aquatic in habits, this animal is related to the English water-rat and therefore included in the sub-family *Microtinae*. (See *VOLE*.) It is, however, of larger size, the head and body being about 12

MUSK-RAT (FIBER ZIBETHICUS)

in. in length and the tail but little less. It is a heavily-built animal, with a broad head and short limbs, the eyes are small, and the ears project little beyond the fur. The fore-limbs have four toes and a rudimentary thumb, all with claws; the hind limbs are larger, with five distinct toes, united by webs at their bases. The tail is laterally compressed, nearly naked, and scaly. The hair consists of a thick soft underfur, interspersed with longer stiff, glistening hairs, which overlie and conceal the former, on the upper surface and sides of the body. The colour is dark umber-brown, almost black on the back and grey below. The tail and naked parts of the feet are black. The musky odour from which it derives its name is due to the secretion of a large gland situated in the inguinal region, and present in both sexes.

The ordinary musk-rat is one of several species of a genus peculiar to North America. It lives on the shores of lakes and rivers, swimming and diving with facility, feeding on the roots, stems and leaves of water-plants, or on fruits and vegetables which

grow near the margin of the streams. Musk-rats are most active at night, spending the day concealed in their burrows in the bank, which consist of a chamber with numerous passages, all of which open under the surface of the water. For winter quarters they build more elaborate houses of conical or dome-like form, composed of sedges, grasses and similar materials plastered together with mud. Their fur is valuable. (See RODENTIA.)

MUSK-SHREW, a name for any species of the genus *Crocidura* of the family *Soricidae* (see INSECTIVORA), but generally used of the common grey musk-shrew (*C. coerulea*) of India which commonly frequents human habitations. The head and body, blue-grey in colour, measure about 6 in., and the tail is rather more than half that length.

MUSLIM: see ISLAM.

MUSLIN, a light cotton cloth said to have been first made at Mosul, a city of Mesopotamia. Muslins have been largely made in various parts of India, whence they were imported to England towards the end of the 17th century. Some of these Indian muslins were very fine and costly. Among the specialties are *Arni muslin*, made in the Madras presidency, and *Dacca muslin*, made at Dacca in Bengal. Muslins of many kinds are now made in Europe and America, and the name is applied to both plain and fancy cloths, and to printed calicoes of light texture. *Swiss muslin* is a light variety, woven in stripes or figures, originally made in Switzerland. *Book muslin* is made in Scotland from very fine yarns. Mulls, jaconets, lenos, and other cloths exported to the East and elsewhere are sometimes described as muslins.

MUSPRATT, JAMES (1793–1886), British chemical manufacturer, was born in Dublin on Aug. 12, 1793. At the age of 14 he was apprenticed to a wholesale druggist, but after a quarrel with his master he went to Spain to take part in the Peninsular War. Returning to Dublin about 1814, he began the manufacture of chemical products, such as hydrochloric and acetic acids and turpentine, adding prussiate of potash a few years later. In 1822 he went to Liverpool and at first he confined himself to the latter product, but in 1823, when the tax on salt was reduced from 7s. to 2s. a bushel, he erected plant for the manufacture of soda from salt by the Leblanc process. In 1828 he built works at St. Helen's and in 1850 he started new works at Widnes and Flint. In 1834–35, in conjunction with Charles Tennant, he purchased sulphur mines in Sicily, to provide the raw material for his sulphuric acid; but on the imposition of the Neapolitan government of a prohibitive duty on sulphur, Muspratt found a substitute in iron pyrites, which was thus introduced as the raw material for the manufacture of sulphuric acid. He died at Seaforth Hall, near Liverpool, on May 4, 1886.

His eldest son, **JAMES SHERIDAN MUSPRATT** (1821–1871), studied chemistry under Thomas Graham at Glasgow and London and under Liebig at Giessen, and in 1848 founded the Liverpool College of Chemistry, of which he acted as director. From 1854 to 1860 he was occupied in preparing a dictionary of *Chemistry . . . as applied and relating to the Arts and Manufactures*, which was translated into German and Russian; a new supplement to the German edition, under the title of *Muspratt's Encyklopädisches Handbuch technischer Chemie*, was completed in 1927.

MUSQUASH: see MUSK-RAT.

MUSSEL, the name given to certain aquatic bivalve molluscs of the class Lamellibranchia. In its most regular usage it is applied to the marine Mytilidae, of which the edible mussel, *Mytilus edulis*, is the most familiar example, and to the fresh-water genus *Anodonta*. The members of the large fresh-water genus *Unio* are sometimes called mussels.

The marine mussels (*Mytilus*, *Modiolaria*, *Modiola*) belong to the sub-order Mytilacea of the order Filibranchia. The edible mussel, *Mytilus edulis*, has a wide distribution. It is found on both sides of the Atlantic and in the Mediterranean, and on the eastern Atlantic seaboard its range extends as far south as Rio de Oro in Morocco. Its habitat is towards low-tide mark, where it lives attached to rocks or on consolidated shingle or sand-banks. It is usually found in large numbers, such mussel-beds sometimes covering several acres and containing millions of individuals.

The Mytilidae have an inequilateral shell, the apex or umbo ap-

pearing to be displaced to one end when compared with that of a cockle, for example. This is due to the imperfect development of the anterior end of the shell. The foot is provided with a byssus, a bunch of hairs secreted in a glandular cavity of the foot. From this cavity the hairs are extruded and harden on contact with the sea-water, forming a means of attaching the mussel to a rock or stone. This fixation is not, however, permanent; the animal can discard the byssus and anchor itself afresh in a new situation. Such a means of anchorage and the faculty of occasionally changing position are highly important in animals which live, as the Mytilidae do, in the tidal zone where gales tend to shift the sand or shingle on which they live, and where the animal is liable to be swept away from its feeding-ground or buried beneath the debris of the shore.

The edible mussel, *Mytilus edulis*, is of considerable economic importance as human food and as bait for edible fishes. In 1922, 1,888 tons of mussels were delivered at Billingsgate market in London. It is very little eaten in the United States. *M. edulis* is considered of fair size for eating when it is 2 in. long, a size attained in three years after the young mussel has settled down. Under favourable conditions it will attain a much greater size. The degree of salinity of the water has a considerable effect on the size of the shell. For example, those mussels which live in the comparatively fresh water of the Baltic sea are often a quarter or one-fifth the size of the North sea forms. Nevertheless, it seems to thrive best in water having a salinity lower than that of normal sea-water. In Great Britain the chief mussel beds are in Morecambe bay (Lancs.) and in the Wash.

There are many genera in the family Mytilidae, which has a wide distribution. They include *Modiolaria*, *Lithodomus* (the date mussel), which bores into rock, *Modiola* and *Myrina*.

The fresh-water mussels are members of the family Unionidae (order Eulamellibranchia) and include the genera *Anodonta*, *Unio*, *Quadrula*, etc. They are mainly found in rivers and lakes. They burrow in the soft mud of the bottom and, living thus in more tranquil conditions than the sea-mussels, have only a weakly developed byssus. The developmental history of these mussels is unique among molluscs, as the young larva (*glochidium*) undergoes part of its development as a parasite on fish. The members of the genus *Unio* and its near allies are of considerable economic importance in the United States, where they are cultivated for their pearly shell, which is used in button-making. At one time the pearls obtained from these animals were widely sought in Europe; but this industry has decayed owing to the introduction of the Orient pearls of Ceylon, etc.

MUSSELBURGH, burgh of regality, Midlothian, Scotland, 5½ m. E. of Edinburgh by the L.N.E.R. Pop. (1921), 17,110. The burgh, which lies on the south shore of the Firth of Forth, is intersected by the Esk and embraces the village of Fisherrow on the left bank of the river. While preserving most of the ancient features of its High Street, the town, with its fine beach and golf course, has tended to become a suburb of the capital. Loretto School, one of the foremost public schools in Scotland, occupies the site of the chapel of Our Lady of Loretto, which was founded in 1534 by Thomas Duthie, a hermit from Mt. Sinai, and was the favourite shrine of Mary of Guise. The 1st earl of Hertford destroyed it in 1544, and after it was rebuilt the Reformers demolished it again, some of its stones being used in erecting the tolbooth. In the west end of the town is Pinkie House, a Jacobean mansion, with a fine fountain, formerly a seat of the abbot of Dunfermline, but transformed in 1613 by Lord Seton. The painted gallery, with an elaborate ceiling, was utilized as a hospital after the battle of Pinkie in 1547, and Prince Charles Edward slept in it after the fight at Prestonpans (1745). Near the tolbooth stands the market cross. At the west end of High Street is a statue of David Macbeth Moir ("Delta," 1798–1851), born in Mussel-

burgh. A bridge of Roman origin crosses the Esk, and Roman remains have been found near it. The chief bridge, which carries the high road from Edinburgh to Berwick, was built by John Rennie in 1807. The principal industries include paper-making, brewing, the making of nets and wire, confectionery, mats, boat-building, pottery, besides saltworks and seed-crushing works. The fishery is confined to Fisherrow, where there is a good harbour. Race meetings and archery contests are held on the links. About 1 m. south-east is the site of the battle of Pinkie, and 2½ m. south-east, on the verge of Haddingtonshire, is Carberry Hill, where Mary surrendered to the lords of the Congregation in 1567, the spot being still known as Queen Mary's Mount. Musselburgh returns one of the five Edinburgh members to parliament.

MUSSET, ALFRED DE [LOUIS CHARLES ALFRED] (1810–1857), French poet, play-writer and novelist, was born on Dec. 11, 1810 in a house in the middle of old Paris, near the Hôtel Cluny. In the summer of 1827 he won the second prize (at the Collège Henri IV.) by an essay on "The Origin of our Feelings." He took up law and medicine but could endure no profession. He was taken by Paul Foucher to Victor Hugo's house, where he met Alfred de Vigny, Prosper Mérimée, Charles Nodier, Sainte-Beuve, and others. His first original volume, *Contes d'Espagne et d'Italie* (1829), had an immediate success, provoked bitter opposition, and produced many unworthy imitations. This volume contained a fantastic parody in verse on certain productions of the romantic school. This was the famous "Ballade à la lune" with its recurring comparison of the moon shining above a steeple to the dot over an *i*. It was, to Musset's delight, taken seriously.

In December 1830 Musset was just twenty years old, and was already conscious of that curious double existence within him so frequently symbolized in his plays—in Octave and Célilo for instance (in *Les Caprices de Marianne*), who also stand for the two camps, the men of matter and the men of feeling—which he has elsewhere described as characteristic of his generation. At this date his *Nuit vénitienne* was produced by Harel, manager of the Odéon. It failed and Musset was disgusted with the theatre.

Musset now belonged, in a not very whole-hearted fashion, to the "Cénacle," but the connection came to an end in 1832. In 1833 he published the volume called *Un Spectacle dans un fauteuil*, and was asked to contribute to the *Revue des deux mondes*. In this he published, in April 1833, *André del Sarto*, and he followed this six weeks later with *Les Caprices de Marianne*. The latter play has perhaps more of the Shakespearian quality—the quality of artfully mingling the terrible, the grotesque, and the high comedy tones—which exists more or less in all Musset's long and more serious plays, than is found in any other of these. Its brilliant dialogue and swiftness of action give it superficially the character of comedy, but throughout there runs the sense of fate.

In 1833 the *Revue* published *Rolla*, a symptom of the *maladie du siècle*. *Rolla*, for all the strain which is not to be denied of Wertherism, has yet a decided individuality. The poem was written at the beginning of Musset's *liaison* with George Sand, and in December 1833 Musset started on the unfortunate journey to Italy. It is well known that the rupture of what was for a time a most passionate attachment had a disastrous effect upon Musset, who was absolutely and completely struck down by the blow. But it was not so well known until Paul de Musset pointed it out that the passion expressed in the *Nuit de décembre*, written about twelve months after the journey to Italy, referred not to George Sand but to another and quite a different woman. As fiction, the story is told in the two volumes called respectively *Elle et lui* by George Sand, and *Lui et elle* by Paul de Musset.

During Musset's absence in Italy *Fantasio* was published in the *Revue*, *Lorenzaccio* is said to have been written at Venice, and not long after his return *On ne badine pas avec l'amour* was written and published in the *Revue*. In 1835 he produced *Lucie*, *La Nuit de mai*, *La Quenouille de Barberine*, *Le Chandelier*, *La Loi sur la presse*, *La Nuit de décembre*, and *La Confession d'un enfant du siècle*, wherein is contained what is probably a true account of Musset's relations with George Sand. To 1836 belong the *Nuit d'août*, the *Lettre à Lamartine*, the *Stances à la Malibran*, the comedy *Il ne faut jurer de rien*, and the beginning of the bril-

liant letters of Dupuis and Cotonet on romanticism. *Il ne faut jurer de rien* is as typical of Musset's comedy work as is *Les Caprices de Marianne* of the work in which a terrible fatality underlies the brilliant dialogue and keen polished characterization. In 1837 was published *Un Caprice*, which afterwards found its way to the Paris stage by a curious road. Mme. Allan-Despreaux, the actress, heard of it in St. Petersburg as a Russian piece. On asking for a French translation of the play she received the volume *Comédies et proverbes* reprinted from the *Revue des deux mondes*. In 1837 appeared also some of the *Nouvelles*. In 1839 Musset began a romance called *Le Poète déchu*, of which the existing fragments are full of passion and insight.

In 1840 Musset passed through a period of feeling that the public did not recognize his genius—as, indeed, they did not—and wrote a very short but very striking series of reflections headed with the words "À trente ans," which Paul de Musset published in his *Life*. In 1841 there came out in the *Revue de Paris* Musset's "Le Rhin allemand," an answer to Becker's poem which appeared in the *Revue des deux mondes*. This fine war-song made a great deal of noise, and brought to the poet quantities of challenges from German officers. Between this date and 1845 he wrote comparatively little. In the last named year the charming "proverb" *Il faut qu'une porte soit ouverte ou fermée* appeared. In 1847 *Un Caprice* was produced at the Théâtre Français. The word "rebonsoir" shocked some of the old school. But the success of the piece was immediate. In 1848 *Il ne faut jurer de rien* was played at the Théâtre Français and the *Chandelier* at the Théâtre Historique. Between this date and 1851 *Bettine* was produced and *Carmosine* written. The poet died on May 2, 1857.

Alfred de Musset now holds the place which Sainte-Beuve first accorded, then denied, and then again accorded to him—as a poet of the first rank. He had genius, though not genius of that strongest kind which its possessor can always keep in check. His own character worked both for and against his success as a writer. He inspired a strong personal affection in his contemporaries. His very weakness and his own consciousness of it produced such beautiful work as, to take one instance, the *Nuit d'octobre*. His *Nouvelles* are extraordinarily brilliant; his poems are charged with passion, fancy and fine satiric power; in his plays he hit upon a method of his own, in which no one has dared or availed to follow him with any closeness. He was one of the first, most original, and in the end most successful of the first-rate writers included in the phrase "the 1830 period." The wilder side of his life has probably been exaggerated; and his brother Paul de Musset has given in his *Biographie* a striking testimony to the finer side of his character. In the later years of his life Musset was elected, not without opposition, a member of the French Academy. Besides the works above referred to, the *Nouvelles et contes* and the *Oeuvres posthumes*, in which there is much of interest concerning the great tragic actress Rachel, should be specially mentioned. (W. H. Po.; X.)

The biography of Alfred de Musset by his brother Paul, partial as it naturally is, is of great value. Alfred de Musset has afforded matter for many appreciations, and among these in English may be mentioned the sketch (1890) of C. F. Oliphant and the essay (1855) of F. T. Palgrave. See also the monograph by Arède Barine (Madame Vincens) in the "Grands écrivains français" series. Musset's correspondence with George Sand was published intact for the first time in 1904.

See M. Donnay, *Alfred de Musset* (1914); C. Maurras, *Les Amants de Venise: George Sand et Musset* (1916), pp. 316; E. Moroncini, *A. de Musset e l'Italia* (Milan, 1921), pp. 228.

MUSSOLINI, BENITO (1883–), Italian statesman and journalist, was born July 29, 1883, at Dovia, in the commune of Predappio (province of Forlì). His father, Alessandro Mussolini, was a blacksmith of internationalist revolutionary and anti-religious opinions, and played an active part in the local Socialist movement, while his mother, Rosa Maltoni, was a school teacher of deep religious convictions; the views of both parents affected young Mussolini in different ways at different stages of his career. He was sent to the Salesian college of Faenza, where he showed considerable intelligence but a passionate, insubordinate spirit. Later he went to the normal school at Forlìmpopoli, and eventually qualified as a school teacher at the age of 18, obtaining an appointment at Gualtieri (province of Reggio Emilia). As a youth he

developed a love of literature and read widely, and soon became interested in the Italian Socialist movement. But he tired of teaching, and determined to go to Switzerland to improve his education. There he earned a precarious livelihood by manual labour of various kinds, but attended the courses at the universities of Lausanne and Geneva, and secured a diploma as teacher of French. He lived mostly among the working classes, and, born organizer as he was, he founded trade unions and even promoted strikes, with the result that he was expelled from one canton after another, and finally from the Confederation. After performing his military service in the Bersaglieri, he returned to teaching, but found time to improve his knowledge of the classics. In 1908 he was involved in the political agrarian conflicts in Romagna, was arrested, tried and condemned to 10 days' imprisonment, and afterwards was under police surveillance as a revolutionary.

At the end of 1908 he went to Trento, where he had been summoned by the local Chamber of Labour as secretary, and he also joined the staff of the local Socialist paper *L'Avvenire*. But when he realised that the Trentino Socialists, in their loathing for the national idea, took their cue from the Vienna Government, Mussolini went over to the *Popolo*, a paper edited and founded by Cesare Battisti, also a Socialist, but above all an Irredentist patriot who was afterwards to serve in the Italian Army during the War, until captured by the Austrians and hanged as a traitor. Here Mussolini took up the study of German literature, and became deeply interested in philosophy, especially in that of Nietzsche. His association with Battisti first inspired him with Irredentist ideas, and after publishing an article stating that "the Italian frontier does not end at Ala" he was arrested and expelled from Austria. On returning to Italy he published an essay of Irredentist tendencies on "The Trentino as seen by a Socialist" in *La Voce*, a periodical printed in Florence which gathered around it some of the most brilliant young *littérateurs* of the day.

The next period of Mussolini's life was wholly devoted to Socialist activity. In 1910 he founded and edited a paper at Forlì called *La lotta di classe*, but while he vigorously supported the ideals of Socialism, he deplored the materialism, as he considered it, of the bourgeois spirit into which the Italian Socialist party had degenerated. He drew further and further away from Marx and Lassalle, feeling more sympathy with the ideas of Baboeuf, Blanqui, Proudhon, and above all with the syndicalism of Sorel. An opponent of parliamentarianism, he reproved the Italian socialists for compounding with the bourgeois parties in order to secure seats in the Chamber and lucrative contracts for bogus co-operative societies; he not only advocated direct action, but also put it into practice whenever he saw a chance of securing real advantages for the proletariat thereby, and, unlike other Socialist leaders, he was ever ready to lead his followers and run risks.

The Tripoli Campaign.—When Giolitti's Government decided to send a military expedition to Tripoli, although not rejecting the idea of war in general, Mussolini opposed this policy because, as he said, unlike the Nationalists, who wanted a vast Italy, he preferred an Italy that should be well cultivated, rich and free. On Sept. 25-27, 1911 he therefore organized a popular movement at Forlì against the Tripoli expedition, inciting the mob to resist the authorities. He was in consequence arrested and condemned to five months' imprisonment. At the congress of Reggio Emilia in 1912, when Bissolati and Bonomi were expelled from the party for supporting the Government's African policy, Mussolini remained one of the die-hard revolutionaries, and in December of that year was made editor of the *Avanti*, the official organ of the party. Under his able editorship the circulation rose from 40,000 to 100,000, and his vigorous leaders gave the paper an entirely new character. He insisted particularly on the necessity for improving the economic and social conditions of the southern provinces, which other Socialist leaders neglected because their inhabitants gave few votes to the party. During the so-called "Red Week" in the Marche and Romagna (June 7-14, 1914), Mussolini was one of the most active leaders of the outbreak. It was on this occasion that he lost many illusions concerning his fellow Socialist leaders. He also realized that the masses were anything but ripe for revolution.

The World War.—The crisis of Mussolini's life came with the outbreak of the World War. From the first he strongly opposed Italy's intervention on behalf of the Central Powers. After Italy's declaration of neutrality he still hesitated, for the conflict was raging within him between the Socialist and the Italian; as a Socialist he favoured war in the belief that it would end war and re-establish the principles of right and justice, while as an Italian he doubted if his people were ready to enter the fray. In the autumn the tendency in favour of intervention had gained ground, and he wrote that Italian unity must be completed; later he approved the Government's military measures, as he realised the danger of keeping Italy alone unarmed amid the general conflagration. But he was ever less in harmony with the official creed of his party, and he expressed the hope that if Italy did intervene her international status would be raised and an economic and social revolution promoted. He resigned the editorship of the *Avanti*, and on Oct. 25 appeared before the Socialist assembly at Milan to justify his conduct. The audience howled at him, with imprecations of "traitor, hireling, assassin!"; but instead of defending himself he violently attacked the other Socialists for their *petit-bourgeois* spirit and insincerity. He ended by saying, "You hate me because you still love me."

He now founded a new paper of his own, *Il Popolo d'Italia*, and his enemies spread the rumour that Mussolini had received money from the French Embassy to support the Allied cause, whereas the sole capital of his new venture was 4,000 lire advanced by advertisers. The *Popolo d'Italia* first appeared on Nov. 15, 1914, and in the leading article Mussolini asked: "Do we wish to drag out a miserable existence under present conditions, content with the *status quo* of the monarchy and the bourgeoisie, or do we wish instead to break up this wretched combination of intrigue and cowardice?" He concluded with a stirring appeal in favour of war. The paper led a precarious existence in wretched premises, and was hardly able to pay the staff. But it gathered around it a number of brilliant young writers fired with enthusiasm for the national cause, although many were Republicans and Socialists.

Audacity was its keynote, and while the *Idea Nazionale* and D'Annunzio appealed to the older and more intellectual middle classes, Mussolini influenced the younger generation and the workers, and he reached the less educated masses through his friend the Syndicalist, Filippo Corridoni (afterwards killed in action), editor of the weekly *Battaglie sindacali*. But he still believed in revolution, and in April 1915 he was arrested for advocating his views at a public meeting; ten days later he was slightly wounded in a duel with the orthodox Socialist Claudio Treves. When on May 24 war was declared he wrote in the *Popolo d'Italia*: "From to-day onwards the nation is called to arms. From to-day onwards we are all of us Italians and only Italians. Now that steel has to meet steel, one single cry issues from our breasts, *Viva l'Italia!*"

In the Trenches.—In Sept. 1915, Mussolini, who had volunteered for active service (as editor of a paper he had a right to exemption), was called up, and served as a private in the Bersaglieri in the trenches along the Isonzo and on the Carso. He did his duty gallantly until he was seriously wounded by the explosion of a trench mortar on Feb. 23, 1917. He spent many months in hospital, and on recovery returned to his work on the *Popolo d'Italia*. He wrote a graphic account of his war experiences in his *Diario di Guerra*. As early as the beginning of 1917 he realised the gravity of the propaganda which the Socialists and neutralists were able to conduct owing to the feebleness of the Government, especially of the Minister of the Interior, Signor Orlando, and after resuming his editorial chair he uttered warnings which were disregarded, as were those of Gen. Cadorna. After Caporetto he was one of the few who never lost heart and in the columns of his paper he issued daily messages of encouragement.

After the armistice, Mussolini opened a campaign in favour of a dignified foreign policy at the Peace Conference, and of adequate recognition for the services of the ex-service men. In reply to the first manifestation of Bolshevism Mussolini founded the first *Fascio di Combattimento* on March 23, 1919, at Milan (see *FASCISM*); and although the first programme of the new group

contained many demagogic demands, the patriotic note was predominant, and Mussolini continued to combat Bolshevik doctrines. With regard to Fiume, he insisted that its Italian character must be secured. When D'Annunzio occupied Fiume the *Popolo d'Italia* lent him its full support.

Mussolini was now bitterly hated by the Socialists, and when at the elections of 1919 he stood as a candidate for Milan, he secured only a few votes and was described by the *Avanti* as "a corpse to be buried in a ditch." A few days later Nitti had him arrested on a charge of "armed plotting against the security of the State" (in connection with his support of D'Annunzio), but did not dare to maintain the arrest, and he was soon liberated. Mussolini now worked harder than ever at his paper, whose circulation increased rapidly; his relaxations were writing plays and playing the violin, and he also took to motoring and aviation, in which sports he showed his usual disregard of danger.

Fascist Discipline.—The seizure of the factories by the workmen in the autumn of 1920 did not meet with Mussolini's disapproval, as one would have expected; he regarded their action as a form of practical syndicalism breaking away from the pusillanimous policy of the official Socialist party. But when the Communists proceeded to organize political murders at Bologna, Modena and Ferrara, Mussolini and his Fascists became the nuclei of the national anti-Bolshevik reaction; it is due to him that the whole Communist-Socialist domination eventually collapsed, first in the Po valley and then throughout Italy. But Mussolini was now coming to the conclusion that it was not enough to defeat and disperse the Reds. The Italian people, he argued, must be made free to recover, to work and produce undisturbed, to fulfil their higher destinies; the incompetent governing caste, ready to compromise on everything, must be swept away and its place taken by the virile youth of the country who had won the War. Fascism was spreading rapidly, and in Nov. 1921 it was organized into a political party, but its discipline still left much to be desired. Mussolini now proceeded to reorganize it and establish it on a strictly hierarchical basis, until its discipline surpassed that of any other organisation in Italy. All ranks of society he regarded as necessary, for he did not wish to repudiate the past. He was, moreover, becoming ever more keenly interested in foreign politics. "I hold that, having broken the pride of Bolshevism, Fascism should become the watchful guardian of our foreign policy." But the movement was extending to every sphere of national life—internal affairs, finance, labour, industry, agriculture. At the elections of May 1921 Mussolini and 35 other Fascist candidates were returned, and together with their allies the 10 Nationalists played an active part in the debates.

During the next 12 months Fascist influence consolidated itself throughout Italy, and the obvious breakdown of the old political parties convinced Mussolini that the time for bold action was fast approaching. At first he thought only of the possibility of a coalition Government comprising Fascist elements, but by the summer of 1922 he felt that a predominantly Fascist Government was conceivable and indeed necessary. The strike of Aug. 1, 1922, promoted by the revolutionary *Alleanza del Lavoro*, was broken by the Fascists, and this fact showed the increasing weakness of Signor Facta's Government, which was no longer able to resist any really energetic action from the right or from the left. In the meanwhile, Mussolini had been shedding the last traces of demagogic ideas, and at a Fascist gathering at Udine on Sept. 29 he openly pronounced himself an upholder of the Monarchy, thereby securing the sympathy of many non-Fascists and of the army. He now made no secret of his intention of seizing power, and said so openly at the Fascist meeting in Naples in October. The march on Rome (see ITALY: History) was organized and directed by Mussolini, and indeed it shows the Mussolini touch in every phase. When the Facta Cabinet resigned the king first sent for Signor Salandra, who tried to form a coalition Government, but Mussolini refused to lend the scheme his support, and Salandra threw up his mandate, whereupon the task was entrusted to Mussolini himself. He formed his Ministry within seven hours, a record for Italy, where, especially during the post-war years, every cabinet crisis had lasted for many days and even weeks. He chose

several non-Fascists as Ministers, but refused to contract an alliance with the parties to which they belonged.

His Reforms.—From the moment he assumed office he set to work with his accustomed energy to overhaul and reform the whole administration, to eliminate inveterate abuses, and infuse a new spirit into the State. He himself assumed the portfolios of Foreign Affairs and the Interior, although the work of the latter he left largely to the under-secretary Aldo Finzi. In June 1924, after the Matteotti affair, he appointed Signor Federzoni Minister of the Interior, but in the following spring, on the resignations of Gen. Di Giorgio and Adml. Thaon di Revel (April 3 and May 5, 1925), he assumed the portfolios of War and Marine, and also that of the new Air Ministry; while leaving great latitude to the under-secretaries, he gradually welded the three ministries into a single department of National Defence.

As a Socialist Mussolini was an anti-Parliamentarian, and even later did not regard the Parliament as the sole organ of national life. His object was to make Italy powerful, prosperous and efficient, in as short a time as possible. But in order to make these reforms lasting he determined that the whole body politic shall be imbued with the Fascist spirit—*fascistizzare la nazione*, as he described it—and he therefore inserted Fascism into every activity of the country (for the details of Mussolini's policy as head of the Government see ITALY: History).

As a Minister, Mussolini's activity was prodigious. Even when he was seriously ill in the spring of 1925, he surprised his friends and disconcerted his adversaries by continuing very largely to conduct his business of government from his bed, and by his quick recovery. While he was immensely popular with the great majority of the people who appreciated the far-reaching benefits of his rule, he had many enemies among the members of the old governing caste, the Socialists, Communists and Republicans and the anti-national freemasons, whose influence he destroyed. His opponents tried to exploit the Matteotti murder (June, 1924) to compromise and overthrow Fascism, but Mussolini's great political ability and his obvious honesty of purpose ward off the attempt.

Settlement of the Roman Question.—His unique contribution to the settlement of the 59 year old Roman Question added great lustre to his name as a statesman. On February 11th, 1929, at the palace of the Lateran in Rome, he was co-signatory with Cardinal Gasparri, Papal Secretary of State, of a treaty by which the Supreme Pontiff became sovereign of a newly created State, "The City of the Vatican." In an address two or three days later, the Pope paid a tribute to Mussolini's "exceptional statecraft," shown in the settlement.

Attempts on Mussolini's Life.—At the end of Oct. 1925, a plot to murder him was discovered by the police, and the would-be murderer, the Socialist ex-deputy Tito Zaniboni, was arrested in the very act; other persons were arrested in connection with the affair, notably Gen. Capello, a leading freemason. The news of the plot aroused general indignation, and Mussolini received a plebiscite of enthusiastic congratulations. On April 7, 1926, as he was leaving the Capitol, where he had inaugurated a surgical congress, an Irishwoman, the Hon. Violet Gibson, fired at him with a revolver, slightly wounding him in the nose. His assailant appeared to be demented. The wound did not prevent him from sailing for Tripoli the following day according to programme. On Sept. 11, 1926, the anarchist Lucetti threw a bomb at the premier's motorcar, but although it exploded and wounded several passers-by, Mussolini escaped unhurt. The would-be assassin was arrested and condemned to 30 years imprisonment. On Oct. 31, while he was returning from the inauguration of the scientific congress at Bologna a youth named Zamboni fired a revolver shot at him and narrowly missed him. Zamboni was instantly lynched by the crowd. This unsuccessful attempt was followed by demonstrations of enthusiasm all over Italy, and new measures were enacted for dealing severely with political crime.

Mussolini is not a finished orator in the classical sense. But every speech bristles with facts, and each phrase contributes to build up the idea which he wishes to assert. On innumerable occasions an apparently difficult, even insoluble, situation has been solved by one of his vigorous speeches. Besides innumerable arti-

cles in *Il Popolo d'Italia*, *Avanti*, *Gerarchia*, etc., he has published *Il mio Diario di Guerra 1915-17* (Milan, 1923), and his speeches have been collected in several volumes. A selection of them has been published in English edited by Baron Quaranta, *Mussolini as revealed in his political speeches, Nov. 1914 to Aug. 1923* (1923).

His biography was published in English by Margherita Sarfatti (Butterworth, 1925). See F. Gueterbock, *Mussolini und die Faschismus* (1923); A. Dressler, *Mussolini* (Leipzig, 1924); L. Roger, *Historie de Mussolini* (1926); Spencer Jones, *Benito Mussolini* (1927); Antonio Beltramelli, *L'uomo nuovo* (new edition, 1928), and Vittorio De Fiori, *Mussolini the Man of Destiny* (1928). See also his own account of his life (Eng. trans. *My Autobiography*, 1928). (L. V.)

MUSSOORIE or **MASURI**, a town and sanitarium of British India, in the Dehra Dun district of the United Provinces, about 6,600 ft. above the sea. Pop. (1921), 8,297, rising to 15,000 in the hot season. It stands on a ridge of one of the lower Himalayan ranges, amid beautiful mountain scenery, and is one of the chief summer resorts for European residents in the plains of the United Provinces. The view from Mussoorie over the valley of the Dun and across the Siwalik hills to the plains is very beautiful, as also is the view towards the north, which is bounded by the peaks of the snowy range. Mussoorie practically forms one station with Landaur, the convalescent depot for European troops, 7,362 ft. above the sea. Some distance off, on the road to Simla, is the cantonment of Chakrata, 7,300 ft. There are numerous schools for Europeans, including St. George's college, the Philander-Smith institute, the Oak Grove school of the East Indian railway, and several Church of England and Roman Catholic institutions, together with a cathedral of the latter faith. The first brewery in India was established here in 1850. The town has botanical gardens, and is the summer headquarters of the Trigonometrical Survey.

MUSSORGSKY, MODEST PETROVICH (1835-1881), Russian composer, was born at Karevo, Pskov, on March 28, 1835, and entered the army at an early age. He was a talented amateur, when his acquaintance with Balakirev and Dargomizsky led him to the serious study of music. In 1857 he left the army and devoted himself to music, though this step entailed earning his living as a government clerk and a prolonged period of poverty. He found an intimate friend in Rimsky-Korsakov. His greatest opera, *Boris Godunov*, based on Pushkin's drama, was produced in St. Petersburg in 1874. *Khovanshchina*, also based on the period of Peter the Great, was finished by Rimsky-Korsakov. Other unfinished works were based on Gogol's *Marriage Broker* and on Flaubert's *Salammbô*. He also wrote exquisite songs and orchestral works, of a realistic national type. Mussorgsky died in the military hospital at St. Petersburg on March 28, 1881. He had taken to drugs and was a mere shadow of his former self.

See M. D. Calvocoressi, *Mussorgsky* (1908, Eng. trans. 1913); M. Montagu-Nathan, *Moussorgsky* (1916); and the article by Rosa Newmarch in *Grove's Dictionary of Music and Musicians*.

MUSTAFA KEMAL (1880-), Turkish soldier and statesman, was born in comparatively modest circumstances in Salonika. His father was a customs officer who afterwards entered the timber trade and died when Mustafa was yet a small child. The boy was brought up and educated by his mother, a woman of character and ability. He completed his primary education in Salonika and entered a secondary school in the same place; but, having been maltreated by his Arabic teacher, he left school, against his family's wish, and secretly entered the military preparatory school. There he proved to be an exceptional student, especially in mathematics. His teacher in mathematics, who was also named "Mustafa," gave him the distinctive surname of "Kemal" (an Arabic word meaning "perfection"), as a tribute to his unusual ability. Such was his popularity at the military academy that, although he already took an active interest in politics and bitterly criticised the despotism of Abdul-Hamid, he was never denounced.

In 1904 he was gazetted lieutenant, but on the same day arrested, and after examination, banished to Damascus. Here, after observing the deplorable condition into which the civil and military organization of the empire had fallen, he founded in

1905 the secret political society "Vatan" ("Fatherland"). From Damascus he was transferred to Jaffa, whence he made his way secretly to Salonika to organize a similar political movement in the European provinces. The association which he founded at Salonika was afterwards affiliated to the Union and Progress Society. The Constantinople Government now again ordered his arrest; but he escaped, and the Government presently forgot him. In 1907 he was promoted and sent to Salonika, where he resumed his revolutionary activities.

When the revolution of 1908 re-established the constitution of 1876, Mustafa Kemal found himself in serious disagreement with the leaders of the victorious Union and Progress party. His political views were more radical than theirs and he protested, though in vain, against the participation of the army in politics. In consequence he abandoned politics for the time and turned his whole energy into his military career, in which he advanced rapidly. He was loved and respected by the younger officers, but some of his superiors mistrusted his uncompromising attitude. In 1911 he went to Tripoli *incognito* to take part in the war against the Italians. There he was promoted major. The first Balkan war was over before he could return; but in July 1913, during the second Balkan war, he was appointed chief of the staff to the newly-organized army corps on the Gallipoli peninsula, where he made a detailed first-hand study of the problem of defending the Dardanelles. After the restoration of peace, he was appointed military attaché at Sofia, with the rank of colonel, and held this post until after the intervention of Turkey in the World War in the autumn of 1914.

Mustafa Kemal believed that Turkey had entered the war prematurely and that Germany was doomed to eventual defeat. Possibly, for this reason, his desire to return to active service was not encouraged; but, on his insistence, he was appointed commander of the forces at Rodosto, and afterwards (in 1915) at the Dardanelles. He inspired the defence of the straits against the British attack—this, when the Turkish high command had lost hope. During the final British assault a splinter of shell right over the heart was intercepted by his watch and he thus escaped with his life.

Mustafa Kemal was then sent to the Caucasus, where he was promoted to the rank of pasha and recovered Bitlis and Mush from the Russians. In 1917 he was posted to the Hejâz. His proposal to recall all the forces in the Hejâz to reinforce the Syrian front was not adopted, but later in the same year he was appointed to the command of the VII. Army Corps in the force which the German general Von Falkenhayn was organizing with a view to the recovery of Baghdad. At this time Germany's intervention in the internal affairs of Turkey had reached its height, and Mustafa Kemal Pasha put himself at the head of the opposition to it. He sent in a succession of reports adverse to the Baghdad expedition, which he thought would end in another disaster, and when his advice was ignored he resigned. He was then transferred to the II. Army Corps, but abstained from taking up his command owing to disagreement on questions of principle with General Headquarters. Sent on a mission to the German G.H.Q. with the heir apparent Vahydu'd-Din Efendi, in the presence of Generals Hindenburg and Ludendorff, he expressed outspokenly his pessimistic views regarding the outcome of the war. In 1918 he yielded to the insistence of Vahydu'd-Din Efendi, who had now meanwhile succeeded to the throne as Sultan Mehmed VI., and accepted command of the VII. Army Corps in Palestine, but all chance of taking the offensive, or even averting disaster, had now disappeared. Mustafa Kemal again distinguished himself, however, in keeping together the remnants of his corps on the retreat which followed General Allenby's great victory, and before the end of September was appointed commander-in-chief of all the corps constituting the so-called Yildirim group.

When the Turkish Government negotiated the armistice of Mudros (Oct. 30, 1918), Mustafa Kemal was opposed to the policy of complete surrender, and after the signature of the armistice retired to Constantinople. The Greek landing at Smyrna on May 16, 1919, which reawakened the Turkish nation, and his appointment by the Ottoman Government in Constantinople as

inspector of the IX. Army Corps in north-eastern Anatolia gave him his chance. His mission, as conceived by the sultan and the grand vizier, was to execute the armistice terms by superintending the disarmament and demobilization of the Turkish army in this remote district. Mustafa Kemal meant to create a nucleus of national resistance against the partition of the country, and therefore accepted with alacrity the position offered him by the unsuspecting Government. As soon as he landed at Samsun he began to organize his new movement locally at Amasia, Tokat and Sivas, and to correspond secretly with other parts of the country. The sultan's government, awaking too late, recalled him to Constantinople, but he went on instead to Erzerum and sent in his resignation to Constantinople. He next convened two congresses, one at Erzerum in July, and the other at Sivas in Sept. 1919. Both congresses endorsed his programme of fighting for national existence to the bitter end, and appointed a standing executive committee under his chairmanship. Thereupon he was outlawed by the Constantinople Government, and relations between the capital and the interior of Anatolia were broken, but all the efforts of the Constantinople Government and the Allied Powers to frustrate Mustafa Kemal's activities simply strengthened his conviction that he had taken the right path.

The political and military history of the new Turkish Nationalist movement, commonly called the "Kemalist" movement, after its founder, is given elsewhere. (See GRAECO-TURKISH WAR; LAUSANNE, CONFERENCE OF; TURKEY.) Mustafa Kemal was in favour of the Nationalists participating in the general election at the close of 1920, but decidedly opposed to the meeting of the Assembly at Constantinople, and his judgment was borne out by the event. On April 23, 1920, Mustafa Kemal gathered together at Angora the Nationalist members of the late Parliament who had escaped from Constantinople, and was elected unanimously president of this new National Assembly.

During the two and one-half years which followed, Mustafa Kemal was the heart and soul of the Turkish national resistance. His exceptional military ability, his keen intellect and his persuasive oratory carried his countrymen through their ordeal. During the summer campaign of 1921, which was the supreme crisis of the Graeco-Turkish War, the Angora assembly appointed Mustafa Kemal generalissimo of the Turkish forces, with unlimited power, and he took personal charge at the front during the 22 days' and nights' fighting of the battle of the Sakaria. During the battle his horse was wounded and the general broke a rib in falling, but he never left the front. After this battle the assembly gave him the rank of field-marshal and the traditional title of "Ghazi" (the victorious).

The destruction of the Greek army, the peace settlement at Lausanne, the abolition of the sultanate, the declaration of the republic and the abolition of the caliphate—were the direct work of Mustafa Kemal. On Oct. 29, 1923, the date on which the Republic was proclaimed, the great national assembly unanimously elected Mustafa Kemal the first president of the republic. In fact, if not in theory, he became dictator. After the external menace had been removed, the internal unity of the nation began to relax. Kemal's repressive policy deprived Turkey of certain talents which she could ill afford to spare. Embitterment reached a climax in June 1926, with the conspiracy of the former Committee of Union and Progress against Kemal's life. He was left in authority, however, and on Nov. 1, 1927 was unanimously reelected. For the revolution in social organisation and the general policy of Westernization carried out by Mustafa Kemal see TURKEY, HISTORY.

(A. J. T.)

MUSTANG, the wild or semi-wild horse of the prairies of North America, the descendant of the horses imported by the Spaniards after the conquest in the 16th century (see HORSE).

MUSTARD. The varieties of mustard-seed of commerce are produced from several species of the genus *Brassica* (family Cruciferae). Of these the principal are the black mustard, *Brassica nigra* (*Sinapis nigra*), the white mustard, *Brassica alba*, and the Sarepta mustard, *B. juncea*. Both the white and black mustards are cultivated to some extent in various parts of England. The white is grown as a salad plant and has come into in-

creasing favour as a forage crop for sheep and as a green manure, for which purpose it is ploughed down when about to come into flower. The black mustard is grown solely for its seeds, which yield the condiment. When white mustard is cultivated for its herbage it is sown usually in July or August, after some early crop has been removed. In about six weeks it is ready either for

feeding off by sheep or for ploughing down as a preparative for wheat or barley.

Brassica nigra occurs as a weed in waste and cultivated ground throughout England and the south of Scotland, and widely in the United States and Canada. It is a large branching annual 2 to 3 ft. high with stiff, rather rough, stem and branches; dark green leaves ranging from lyrate below to lanceolate above, short racemes of small bright yellow flowers one-third of an inch in diameter and narrow smooth pods. *B. alba* is more restricted to cultivated ground in Great Britain and has only sparingly escaped from cultivation in the United States; it is distinguished from black mustard by its smaller size, larger flowers and seeds, and spreading rough hairy pods with a long curved beak.

BY COURTESY OF THE NATURAL HISTORY MUSEUM

WHITE MUSTARD (*SINAPIS ALBA*), SHOWING FLOWERS AND FRUITS (SILIQUEAS)

The pungency and odour to which mustard owes much of its value are due to an essential oil developed by the action of water on two chemical substances contained in the black seed. These bodies are a glucoside (see GLUCOSIDES) termed by its discoverers myronate of potassium, but since called sinigrin, $C_{10}H_{18}KNS_2O_{10}$, and an enzyme, myrosin. The latter substance in presence of water acts on sinigrin, splitting it up into the essential oil of mustard, a potassium salt, and sugar. It is worthy of remark that this reaction does not take place in presence of boiling water, and therefore it is not proper to use very hot water (above $120^{\circ} F$) in the preparation of mustard. Essential oil of mustard is in chemical constitution an isothiocyanate of allyl C_3H_5NCS . The seed of white mustard contains in place of sinigrin a peculiar glucoside called sinalbin, $C_{30}H_{44}N_2S_2O_{16}$, in several aspects analogous to sinigrin. In presence of water it is acted upon by myrosin, present also in white mustard, splitting it up into acrinyl isothiocyanate, sulphate of sinapin and glucose. The first of these is a powerful rubefacient, whence white mustard, although yielding no volatile oil, forms a valuable material for plasters.

Both as a table condiment and as a medicinal substance, mustard has been known from a very remote period. Under the name of *νᾰπν* it was used by Hippocrates in medicine. The form in which table mustard is now sold in the United Kingdom dates from 1720, about which time Mrs. Clements of Durham hit on the idea of grinding the seed in a mill and sifting the flour.

The volatile oil distilled from black mustard seeds after maceration with water is official in the British Pharmacopoeia under the title *Oleum sinapis volatile*. It is a yellowish or colourless pungent liquid, soluble only in about fifty parts of water, but readily so in ether and in alcohol. From it is prepared, with camphor, castor-oil and alcohol, the *linimentum sinapis*. Used internally as a condiment, mustard stimulates the salivary but not the gastric secretions. It increases the peristaltic movements of the stomach very markedly. One drachm to half an ounce of mustard in a tumblerful of warm water is an efficient emetic, acting directly upon the gastric sensory nerves, long before any of the drug could be absorbed so as to reach the emetic centre in the brain. The heart and respiration are reflexly stimulated, mustard being thus the only stimulant emetic.

MUSTARD GAS. The name given to dichlorodiethyl sulphide, by far the most devastating gas used in the World War. The fact that it was indestructible and gave off small quantities of vapour for a considerable period added to its potency. The inflammation of the respiratory passages which resulted either proved fatal or rendered the lungs subject to subsequent bacterial infection. (See RESPIRATION.)

MUSTARD OILS, a general term applied to compounds related to allyl mustard oil, the principal constituent of mustard oil obtained by distilling black mustard seeds (*Sinapis niger*). These seeds contain a glucoside (*q.v.*) termed potassium myronate which undergoes a fermentative change due to an enzyme (*q.v.*), myrosin, also present in the seeds. *Allyl mustard oil* (allyl isothiocyanate), $C_3H_5 \cdot N : C : S$, is a colourless liquid sparingly soluble in water and boiling at $151^\circ C$; it has a sharp pungent odour and produces blisters on the skin, whence the efficacy of the mustard poultice as a counter-irritant. It can be prepared synthetically by heating allyl sulphide ($C_3H_5)_2S$, with potassium thiocyanate. The odour and taste of mustard (*q.v.*) are due to this substance.

The analogues of allyl isothiocyanate are readily prepared by the action of carbon bisulphide on primary amines, when alkyl dithiocarbamates are formed which on distillation with mercuric chloride yield the corresponding mustard oils. These compounds are colourless liquids with pungent irritating odours. This general reaction proceeds so smoothly that it is employed as a distinctive test for primary amines. (See AMINES.) Methyl and ethyl mustard oils are thus obtained from methylamine and ethylamine respectively; the former, a solid, melts at $35^\circ C$ and boils at $119^\circ C$; the latter is liquid and boils at $134^\circ C$. Phenyl mustard oil from aniline is a colourless liquid boiling at $222^\circ C$.

MUSURUS, MARCUS (c. 1470–1517), Greek scholar, was born at Rhythymna (*Retimo*) in Crete, and was a pupil of John Lascaris at Venice. He was professor of Greek at Padua and Venice, and died in 1517. Since 1493 Musurus had been associated with Aldus Manutius, and belonged to the "Neacademia," a society founded by Manutius and other learned men for the promotion of Greek studies. Many of the Aldine classics were brought out under Musurus's supervision, and he is credited with the first editions of the scholia of Aristophanes (1498), Athenaeus (1514), Hesychius (1514), Pausanias (1516).

See R. Menge, *De M. Musuri vita studiis ingenio*, in vol. 5 of M. Schmidt's edition of Hesychius (1868).

MUTATION: see VARIATION: *Experimental*; HEREDITY; EVOLUTION.

MUTIAN, KONRAD (1471–1526), German humanist, was born in Homberg on Oct. 15, 1471 of well-to-do parents named Mut, and was subsequently known as Konrad Mutianus Rufus, from his red hair. At Deventer under Alexander Hegius he had Erasmus as schoolfellow; he took the master's degree at Erfurt in 1492. From 1495 he travelled in Italy, taking the doctor's degree in canon law at Bologna. Returning in 1502, the landgraf of Hesse promoted him to high office. The post was not congenial; he resigned it (1503) for a small salary as canonicus in Gotha. The circle which gathered round Mutian at Erfurt, known as the *Mutianischer Bund*, included Eoban Hess, Crotus Rubeanus, Justus Jonas and other leaders of independent thought. He wrote little himself, but inspired others. He desired the reform of the Church, but not schism. Like Erasmus, he was with Luther in his early stage, but deserted him in his later development. Though he had personally no hand in it, the *Epistolae obscurorum virorum* (due especially to Crotus Rubeanus) was the work of the Reuchlinists in his *Bund*. He died at Gotha on March 30, 1526.

See F. W. Kampschulte, *Die Universität Erfurt* (1858–1860); C. Krause, *Eobanus Hessus* (1879), and *Der Briefwechsel des Mutianus Rufus* (1885).

MUTILATIONS AND DEFORMATIONS. In every part of the world to-day, both in civilised as well as uncivilised communities some form of mutilation of the human body is found; but the widest variety of mutilations as well as the most severe occur among the more primitive peoples.

Early historians and writers, long before the Christian era, show that in those days such mutilations as tattooing and cir-

cumcision, as well as skull deformation, were well known. Some form of mutilation was probably practised from earliest prehistoric times. On the cave walls of France and Spain, where Aurignacian and Magdalenian man painted the mammoth, elephant and woolly rhinoceros during the closing phases of the last Ice Age (see *STONE AGE*), are painted hands which indicate the removal of one or more finger joints, a practice common to-day in South Africa, India and elsewhere. The reason for this mutilation on the part of prehistoric man can only be conjectured by analogy with these modern primitive peoples. In the Wellcome Historical Medical Museum in London, there is exhibited a skeleton of an early man from a prehistoric grave at Gebel Moya in the Sudan. Found close to the jaw is a stone stud exactly similar to the lip studs worn by Nilotic peoples today. Other evidence may be found in folk tales; early paintings and carvings, and by a careful interpretation of objects found in the graves. The motives behind mutilation may be classified as: Tribal Convention; Adornment; Initiation Ceremonial; Religion; Punishment and Health.

Skin.—Tattooing consists of puncturing the skin in the pattern desired and rubbing in colouring material so that the pattern is indelibly fixed. In New Zealand the Maoris brought tattooing to a very high art, and the intricate patterns with which they adorned their faces were executed with exquisite workmanship and taste. In China, Borneo, India and other parts of the Far East tattooing is prevalent, and thence has been introduced into Europe, chiefly by sailors. Arms, legs, body and face are all considered suitable surfaces for decoration. To-day tattooing saloons exist in London and in many of the bigger sea-ports. True tattooing, but of a less lasting nature, is occasionally found in parts of Africa, and must not be confused with scarification.

Scarification.—This consists of cutting deep marks into the skin and rubbing in charcoal and other irritant material to keep open the wound which eventually is allowed to heal but which leaves a deep scar. Sometimes the wound is so treated that a shiny "keloid" instead of a flat scar results. Scarification occurs all over Africa for reasons as numerous as they are different. Very frequently small scars are made on the face which serve as tribal and clan marks. Often elaborate patterns are worked out on the chest for purely personal adornment; these are especially good on the West Coast. Sometimes the object of the operation is semi-magical, women of many African tribes being scarified on the abdomen during pregnancy. At other times, scarification is merely the result of surgical treatment and is the consequence of rather crude cupping methods followed by the application of an irritant powder. In Australia the aborigines scarify their arms and chests, which often show great black keloids representing many years of patient work, the wound being opened up from time to time and fresh irritants applied.

Hair.—Depilation by some means or other, has been practised by primitive peoples for hundreds of years, while all modern civilised peoples still continue to remove unwanted hair by various methods. One of the commonest primitive methods of hair removal is by plucking out each individual hair by its root, every time it grows. By starting at an early age the time comes when the hair on the parts so treated could only be grown sparsely even if desired. This plucking is usually done with the aid of special tweezers some of which—as those in use among the Akamba in Kenya Colony—are beautifully made. Depilation by plucking is common all over Africa and in many parts of the East and Oceania, and the areas so treated are more especially the face and pubic regions, and chest and under the arms. Some individuals even go to the length of removing all body hair.

Shaving of the face, as well as of the scalp, is a common practice among primitive people, and may be carried out with such instruments as a piece of broken glass, or a special iron blade. It is usually done dry, without the use of water or lather. Depilation by singeing, as well as by the use of ointments occasionally occurs. Removal of the hair is usually due to tribal custom, as hairy people are despised and often unable to find a mate.

Head.—There are few if any parts of the world where some portions of the head and face entirely escape mutilation, but the

most commonly maltreated are the ears, nose, lips and teeth. Skull deformation may be the result of deliberate intention, or of chance. In some tribes, especially in America every individual was intentionally treated as a child with the direct view of reducing the skull to a certain shape. In other cases, as in parts of Africa, deformation is the unintentional result of the local methods of carrying water pots or loads on the head. Young children, especially girls, start such work long before the skull is properly developed and the result is a definite and fairly uniform deformation. Skull deformation occurs in nearly every part of the world, though commonest in the Americas and least common, if at all existent, in Australia. Intentional deformation is carried out from various motives, sometimes a long pointed head, sometimes a flat depressed head being the shape required. Various methods are employed, commonest of which are by bandaging, and by tying the child's head to a flat board fixed to the occipital region.

Ears.—These are pierced to carry earrings all the world over, indeed very few, primitive or civilised peoples, leave the ears totally un mutilated, though the Andamanese, Bushmen and true Baganda are reported as doing so. Both the ear lobes, as well as the cartilage round the top of the ear, are commonly pierced. This is usually done during childhood and a small piece of wood is inserted into the wound which is then left to heal. Later this plug is removed and a larger one inserted, the process being continued until the required size of hole is obtained by reason of this continual stretching. In many countries both sexes treat their ears in this way, while in others it is confined to one or other sex. The greatest distensions are to be found in Borneo and East Africa. In both these places lobes are often seen so stretched that they hang down to the shoulder, with holes so large that it would be possible to pass a closed fist through them. In all these ear mutilations adornment is the end in view. Large carved wooden plugs, carved stone ornaments, metal rings and fibre and paper rolls, all are used as earrings, while to-day even earthenware jam pots and circular cigarette tins are popular in some parts of Africa.

In some tribes such as the Kikuyu, a husband if displeased with his wife breaks the lobe of her ear with his hands.

Nose.—The nose is often mutilated for purposes of personal adornment especially in India, and the East, as well as in New Guinea and Polynesia, S. America, Australia and in parts of Africa. Nose ornaments also signify social rank. Sometimes it is the alae, and sometimes the septum which is perforated. Often only a small hole is made through the septum from which a gold ring or other jewel is suspended; at other times the hole in the septum is big enough for a finger to be passed through. Elsewhere one, and occasionally both, nostrils are pierced and distended to carry coloured studs, sometimes of unbelievable size, as among the Makonde of Portuguese East Africa. Nose ornaments are more common with women than men, but in New Guinea and especially among the Tugeri and the Solomon Islanders, the men wear great pointed sticks, or sometimes the tusks of wild pig through holes in the nose.

Lips.—In several parts of Africa, especially in the Congo, the south east Tanganyika Territory, and the upper reaches of the Nile, and among the Botocudo of S. America enormous plates and plugs are inserted in hugely distended holes, cut in the upper and lower lips. The lip studs and pins of the Nilotic peoples of Uganda, Kenya Colony and the Sudan are usually small and made of ivory, rock crystal or stone, and are inserted through the upper and lower lips or both. Other lip mutilations include pricking and rubbing with irritant to cause them to swell. This is done in parts of West Africa.

Teeth.—Over the greater part of Africa, as well as in Australia, New Guinea and elsewhere, it is a common practice to remove one or more front teeth in the upper or lower or both jaws. Sometimes the ceremonial knocking out of the teeth accompanies initiation and is a test of ability to bear excruciating pain unflinching; sometimes it is simply a matter of custom; sometimes it serves as a tribal mark, while yet another reason given is the fear of lock-jaw. The removal of the teeth is in this case a precaution which would enable the patient to be fed if

the disease were contracted.

Another common practice in Africa, found also in Southern India, is the filing or chipping of teeth to serve either as a tribal mark or as an initiation step, or for both purposes. The Akamba and certain Congo peoples file their incisors to sharp points, and for some unknown reason this was considered by early travellers as a sign of cannibalism—a most erroneous view. The Eskimo file the teeth to make them shorter and less like those of dogs and in south and central Africa the incisors are filed to all sorts of shapes and patterns as described by Dr. G. Turner in the *Transvaal Medical Journal* for 1911.

The Dyaks of Borneo and other people in the East, occasionally drilled holes in the teeth, into which plugs of gold were driven to serve as ornament. This method of adornment was also used in ancient Mexico, precious stones being inlaid in the teeth.

Tongue, Cheeks and Neck.—Among the Bateso of East Africa a hole is sometimes bored through the tongue and a brass ring bearing one or two beads is inserted. The cutting out of the tongue was once a legal penalty in Europe, and has only recently been forbidden in some parts of Africa.

The Aleutian Islanders bored a hole through each cheek through which seal's whiskers were stuck. Feathers are put through holes in the cheek in parts of S. America.

The *Padang* of the South Shan States deform the necks of their womenfolk by making them wear—from early childhood onwards—high metal collars whose length is gradually increased; this eventually produces such elongation and dislocation of the neck that if the collars were removed the wearers would not be able to hold up their heads.

Eyes and Body.—Putting out eyes as a punishment for various crimes has existed at different times all over the world—Europe included. Priests and worshippers of certain eastern cults still gash and cut themselves with knives as did the priests of Baal in olden times. In parts of Africa it was once a practice to cut off the breasts of an unfaithful wife.

Limbs.—In former times both in England, and Europe generally, amputation of one or more limbs was a common punishment for crime (see Pike's *History of Crime in England*, 1893), and this method has only been suppressed in parts of Africa, as in the Congo and Uganda, by the European governments.

For purposes other than punishment and medical necessity, amputation consists chiefly of cutting off the finger joints, especially the little finger. In South Africa this is either done as mourning, or as a magical preventative measure in the case of a child born to a mother whose last baby was still-born. In Southern India grandmothers used (in some castes) to have to cut off one joint for each grandson born to them. In the Tonga Islands the practice is also considered as of magical importance against disease. There is too the bandaging of girl children's feet to prevent their development. This Chinese practice is now prohibited.

MUTINY: see MILITARY LAW and COURT MARTIAL.

MUTIS, JOSÉ CELESTINO (1732–1808), Spanish naturalist, was born at Cadiz on April 6, 1732. He received his bachelor's degree at the University of Seville and afterwards studied medicine at Madrid where in the general hospital he became for a time a lecturer in anatomy. His preference, however, was for the study of mathematics and natural science, especially botany. He became one of the first disciples of the Swedish botanist, Linnaeus (*q.v.*), in Spain. Attracted by the wide and fruitful fields of study which South America then afforded he sailed in 1760 for New Granada (Colombia), accompanying the Spanish viceroy as physician. In New Granada he occupied himself collecting and describing plants both from the lowlands and from the higher Andean regions, but he did not neglect medicine as is shown by his appointment as king's physician in the viceroyship. He spent much time on sanitary problems such as the establishment of proper cemeteries, the prevention of small-pox and the reduction of malaria. He put into general use many American herbs, the properties of which he had studied, among them *ipeacuanda*, guaco and Peruvian balsam. Some of these, such as the cinnamon laurel of the Andes, he made known in Europe. His

favorite study, however, was quinine, which he studied from every angle from the distribution of the different species of cinchona down to experiments in the curative properties of the drug. His *El Arcano de la Quina* was published in 1793. Later studies were published in the *Papel Periodico* and after his death by his nephew, Sinforoso Mutis, who completed and arranged his notes on the subject. His work probably had much to do with making possible the colonization of malaria-infested regions. His work attracted the attention of the king who created the Royal Botanical Expedition of New Granada and placed Mutis at its head. With 18 of his best students, Mutis carried out a systematic survey in which material was collected for the monumental *Flora de Bogotá ó de Nueva Granada* which he planned in 13 folio volumes. Because of his immense activity in other lines only the first volumes of this intended work were arranged at his death. For the remaining volumes he left manuscripts, notes, illustrations and sketches in such profusion that only some one knowing his schemes of arrangement could have finished the work. Among these botanical riches were 6,480 illustrations, admirable in precision and colour, which were intended for an atlas volume. This material, amounting to over 4,000 folios of loose manuscripts, and his collection of over 20,000 plants were sent after his death to the Botanical Garden at Madrid, where they are preserved. Mutis was instrumental in bringing Alexander von Humboldt to New Granada at the beginning of the 19th century and aided him in his work. Humboldt formed a high opinion of Mutis, whose work had completely surprised him. His work *Plantas Equinocciales* and later *Ms Geografía de las Plantas* were both dedicated to Mutis. For 18 years Mutis carried on a correspondence with Linnaeus, much of which was published in *A Selection of the Correspondence of Linnaeus* (1821). He furnished many specimens of plants which the Swedish naturalist described. Linnaeus named in his honour the beautiful genus *Mutisia*, of the family Compositae, comprising some 50 species of plants found in South America. He died at Bogotá on Sept. 11, 1808.

See A. F. Gredilla, *Biografía de José Celestino Mutis* (1911); F. González Suárez, *Memoria histórica sobre Mutis y la expedición botánica de Bogotá* (2nd ed., 1905); Diego Mendoza, *Expedición botánica de José Celestino Mutis* (1909).

MUTRACHA: see CASTE.

MUTSU, MUNEMITSU, COUNT (1842-1896), Japanese statesman, was born in 1842 in Wakayama. A vehement opponent of "clan government"—that is, usurpation of administrative posts by men of two or three fiefs, an abuse which threatened to follow the overthrow of the Tokugawa *shogunate*—he conspired to assist Saigo's rebellion and was imprisoned from 1878 until 1883. While in prison he translated Bentham's *Utilitarianism*. In 1886, after a visit to Europe, he received a diplomatic appointment, and held the portfolio of foreign affairs during the China-Japan War (1894-95), being associated with Prince (then Count) Ito as peace plenipotentiary. He negotiated the first of the revised treaties (that with Great Britain), and for these various services he received the title of count. He died in Tōkyō in 1896.

MUTSUHITO: see MEIJI TENNO.

MUTTON. Next to beef and pork, mutton is the most popular form of meat among carnivorous peoples, but its consumption is relatively small except in Great Britain. The total number of sheep in the world, according to the statistics published by the International Agricultural Institute, is rather larger than that of cattle (601 as compared with 547 millions), but every head of cattle means 12 times as much meat as a sheep.

There was a serious depletion of the world's stock of sheep, as of cattle (see MEAT), during the war, but the loss was replaced.

NUMBER OF SHEEP (in thousands)

	1913	1926
Europe	191,671	194,916
N. and Central America	55,083	48,052
S. America	100,392	81,144
Asia	57,987	66,340
Africa	74,260	82,288
Oceania	109,331	128,507
Total (in thousands)	588,724	601,247

Of the number credited to Oceania about four-fifths are in Australia and the remainder in New Zealand. In other words, the sheep of Australia are about 100 millions and of New Zealand about 25 millions. But New Zealand now (1928) exports over five times as much mutton and lamb as Australia. The chief reason for this is that from the earliest days sheep were bred and kept in Australia for wool production and the carcass was regarded as having practically no commercial value. The Merino breed was kept almost exclusively and as recently as 1891 over 97% of the sheep kept in New South Wales were of that type.

In New Zealand sheep-breeding was in the first instance adopted, as in Australia, for the production of wool.

International Mutton Trade.—Attempts were made, especially in Australia, to export some of the surplus mutton by tinning or canning it. The same course was adopted in the case of beef and an overseas trade was established. Australian tinned meat was exhibited at the Great Exhibition in London in 1851. In the course of the next few years it became well-known and widely used. The introduction of refrigeration provided a better means of dealing with meat for export, although tinned meat still finds an extensive market for special purposes. The supply is likely to be maintained by meat-exporting countries because canning, or tinning, provides an outlet for the "trimmings" of carcasses.

The total quantity of mutton and lamb shipped from all exporting countries in 1927 was 300,000 tons. All of this was frozen, i.e., it was subject, before shipment, to a temperature of from 10° to 15° F and kept at, or about, that temperature until it was deposited in cold storage at the port of destination.

The quantity in tons exported from each of the main sources of supply in 1927 was:—

Argentina	71,468
Australia	25,586
Chile (Patagonia)	27,760
New Zealand	139,000
Uruguay	27,146

The total quantity which reached the United Kingdom in that year was 276,163 tons.

British Consumption.—The improvement of sheep for mutton began in England in the latter part of the 18th century, and since then mutton and lamb have gradually come to be recognised as a regular part of the dietary of English households. It appears, however, from the calculations made by the Ministry of Agriculture and Fisheries that there was a substantial reduction in the consumption of mutton and lamb during the war and that this has not been since recovered. It is estimated that the average annual pre-war production in England and Wales was 194,000 tons, and that in the quinquennium ending in 1927 it was not more than 130,000 tons although in the latter year it had risen to 156,000 tons. This reduction was attributable to the serious depletion of the flocks of the country at the end of the war. Imports were also greatly reduced under war conditions and in 1918 amounted to no more than 112,000 tons. By 1923 the imports had reached 339,000 tons, which was much in excess of the pre-war quantity, but the total supply was reduced.

United States.—The relative proportion of mutton consumption in the United States is less than one-fifth that of England, and in comparison with that of beef and pork it is of minor significance. There is no recordable surplus for export and imports are negligible. The production which reached a peak of 389,500 tons in 1912 declined rapidly to 237,500 tons in 1918, but after 1922 a steady gain increased the total for 1927 to 327,000 tons. The curve for consumption followed closely that of production, except that since 1922 it has shown but a slight rise and the gap between the two has widened. Consumption in 1927 was but 270,000 tons. (R. H. R.)

Braxy Mutton.—The flesh of sheep that have died of "braxy," a Scotch name including several disorders of sheep, of which the chief are (1) an intestinal disorder accompanied by diarrhoea and (2) a general infection associated with acute gastro-enteritis. Formerly, braxy mutton was eaten to a considerable extent but modern views as to the necessity of complete healthiness in animals used for food have restricted its consumption.

MUTTON-BIRD: see SHEARWATER.

MUTTRA or **MATHURA**, a city and district of British India in the Agra division of the United Provinces. The city is on the right bank of the Jumna, 30 m. above Agra; pop. (1921), 52,840. It is an ancient town, mentioned by Fa Hien as a centre of Buddhism about A.D. 400; his successor Hsüan Tsang, about 650, states that it then contained twenty Buddhist monasteries and five Brahmanical temples. It was sacked by Mahmud of Ghazni in 1017-18; about 1500 Sultan Sikandar Lodi utterly destroyed all the Hindu shrines, temples and images; and in 1636 Shah Jahan appointed a governor expressly to "stamp out idolatry." In 1669-70 Aurangzeb visited the city and continued the work of destruction. Muttra was again captured and plundered by Ahmad Shah with 25,000 Afghan cavalry in 1756. The town still forms a great centre of Hindu devotion, and large numbers of Vaishnavite pilgrims flock annually to the festivals. Temples and bathing-stairs line the river bank. The majority are modern, but the mosque of Aurangzeb, on a lofty site, dates from 1669. Most of the public buildings are of white stone, handsomely carved. There are an American mission, a Roman Catholic church, a museum of antiquities and a cantonment for a British cavalry regiment. Cotton, paper and pilgrims' charms are the chief articles of manufacture.

The DISTRICT OF MUTTRA has an area of 1,450 sq.m. It consists of an irregular strip of territory lying on both sides of the Jumna. The general level is only broken at the south-western angle by low ranges of limestone hills. The eastern half consists for the most part of a rich upland plain, abundantly irrigated by wells, rivers and canals, while the western portion, though rich in mythological association and antiquarian remains, is comparatively unfavoured by nature. The population in 1921 was 619,138. The principal crops are millets, pulse, cotton, wheat, barley and sugar cane. The eastern half of the district is watered by the Agra canal, which is navigable, and the western half by branches of the Ganges canal. The district is served by the Rajputana and other railways.

The central portion of Muttra district forms one of the most sacred spots in Hindu mythology. A circuit of 84 kos around Gokul and Brindaban bears the name of the Braj-Mandal, and carries with it many associations of earliest Aryan times. Here Krishna and his brother Balarama fed their cattle upon the plain; and numerous relics of antiquity in the towns of Muttra, Gobardhan, Gokul, Mahaban and Brindaban still attest the sanctity with which this holy tract was invested. During the Buddhist period Muttra became a centre of the new faith. After the invasion of Mahmud of Ghazni the city fell into insignificance till the reign of Akbar; and thenceforward its history merges in that of the Jats of Bharatpur, until it again acquired separate individuality under Suraj Mal in the middle of the 18th century. The whole of Muttra passed under British rule in 1804.

MUTULE, in architecture, a rectangular block, beneath the soffit, or under side of the projecting portion of the cornice of the Doric order. (*See ORDER*.) It is usually decorated on the under side with guttae (*q.v.*), or little cylindrical projecting blocks. In Greek work its lower side is inclined, following approximately the roof slope; in Roman and Renaissance work it is generally level and is crowned with a cap moulding. In origin it is probably a stone representation of an original projecting wooden rafter end.

MUZAFFAR-ED-DIN, shah of Persia (1853-1907), the second son of Shah Nasr-ed-Din, was born on March 25, 1853. He was in due course declared *vali ahd*, or heir-apparent, and invested with the governorship of Azerbaijan, but on the assassination of his father in 1896 it was feared that his elder brother, Zill-es-Sultan, the governor of Isfahan, might prove a dangerous rival, especially when it was remembered that Muzaffar-ed-Din had been recalled to Teheran by his father upon his failure to suppress a Kurd rising in his province. Muzaffar-ed-Din was duly enthroned, with the support of the British and Russian governments, on June 8, 1896, the Russian general Kosakowsky, commander of the Persian Cossacks, presiding with drawn sword.

Towards the end of 1896 the Amin-es-Sultan, who had been grand vizier during the last years of Nasr-ed-Din's reign, was disgraced, and Muzaffar-ed-Din announced his intention of being

in future his own grand vizier. The Amin-ad-Dowla, a less masterful servant, took office with the lower title of prime minister. The financial difficulties of the Government, enhanced by the shah's colossal extravagance, gave a great opportunity to the Russians, who provided a Persian loan, and extended their influence in Persia. At the beginning of 1900 a fresh gold loan was negotiated with Russia, and a few months later Muzaffar-ed-Din started on a tour in Europe by way of St. Petersburg (Leningrad), where he was received with great state. He visited the Exhibition of 1900, and while there an attempt on his life was made by a madman named François Salson. By the end of 1901 his treasury was again empty; but a fresh Russian loan replenished it and in 1902 he again came to Europe, paying on this occasion a State visit to England. On his way back he stopped at St. Petersburg, and at a banquet given in his honour by the tsar toasts were exchanged of unmistakable significance. None the less, during his visit to King Edward VII. the shah had been profuse in his expressions of friendship for Great Britain, and in 1903 a mission went to Teheran to invest him with the Garter.

The shah's misguided policy had created widespread disaffection in the country, and the brunt of popular disfavour fell on the atabeg (the title by which the Amin-es-Sultan was now known), who was once more disgraced in Sept. 1903. The war with Japan now relaxed the Russian pressure on Teheran, and at the same time dried up the source of supplies; and the clergy, giving voice to the general misery and discontent, grew more and more outspoken in their denunciations of the shah's misrule. Muzaffar-ed-Din made another journey to Europe in 1905; but he failed to obtain further supplies at St. Petersburg. In the summer of 1906 popular discontent culminated in extraordinary demonstrations at Teheran, which practically amounted to a general strike. The shah proclaimed a liberal constitution, the first parliament being opened by him on Oct. 12, 1906. Muzaffar-ed-Din died on Jan. 8, 1907, being succeeded by his son Mohammed Ali Mirza.

MUZAFFARGARH, a town and district of British India, in the Punjab. The town is near the right bank of the river Chenal, with a railway station. (Pop.) (1921), 5,386. Its fort and a mosque were built by Nawab Muzaffar Khan in 1794-1796.

The District of Muzaffargarh occupies the lower end of the Sind-Sagar Doab. Area, 6,052 sq.m. In the northern half of the district is the wild *thal* or central desert, an arid elevated tract with a width of 40 m. in the extreme north, which gradually contracts until it disappears about 10 m. south of Muzaffargarh town. In cold weather large herds of camels, owned by the povindah merchants of Afghanistan, graze upon the sandy waste. The district forms part of Multan (*q.v.*). The population in 1921 was 568,478. The principal crops are wheat, pulse, rice and indigo. The boundary rivers are navigable, besides furnishing irrigation channels, originally constructed under native rule.

MUZAFFARPUR, a town and district of British India, in the Tirhut division of Behar and Orissa. The town is on the right bank of the Little Gandak river, and has a railway station. Pop. (1921), 32,755. The town is well laid out along two lakes, which originally formed part of the river bed, and is an important centre of trade, being on the direct route from Patna to Nepal. It is the headquarters of the commissioner of the Tirhut division, also of the Behar Light Horse, first raised as a volunteer corps in 1862.

The DISTRICT OF MUZAFFARPUR has an area of 3,036 sq.m. and a population (1921) of 2,754,945. It is a fertile, alluvial plain watered by the Great Gandak, Baghmati and Little Gandak, and by their tributaries. The level plain is dotted with groves of mangoes and clusters of bamboo. It is closely cultivated and densely populated, the average density being 907 per sq.m. Rice is the chief grain crop. The indigo industry, almost extinguished by the synthetic dye, has been largely replaced by sugr. The village of Basarh north-west of Hajipur is identified with the ancient Vaisali, the scene of the second great Buddhist Council. Excavations have laid bare the remains of buildings dating back to about A.D. 300; hundreds of seals of the 4th or 5th century A.D. were also unearthed. At Kolhua, 3 miles to the N.W., is a stone pillar crowned by a lion, set up by the emperor Asoka to mark a stage of his journey to Nepal in 249 B.C.

MUZIANO, GIROLAMO (1528–1592), Italian painter, was born at Acquafredda, near Brescia, in 1528. He died in Rome, and was buried in the church of Santa Maria Maggiore. He came to Rome about 1550, where his pictures gained him the name of *Il Giovane de' paesi* (the young man of the landscapes). His great picture of the "Resurrection of Lazarus" established his fame. As superintendent at the Vatican, he developed mosaic as a perfect imitation of painting. He helped to found the Academy of St. Luke in Rome.

Many of Muziano's works are in the churches and palaces of Rome; he also worked in Orvieto and Loreto. In Santa Maria degli Angeli, Rome, is one of his chief works, "St. Jerome preaching to Monks in the Desert"; his "Circumcision" is in the church of the Gesù, his "Ascension" in the Araceli, and his "St. Francis receiving the Stigmata" in the church of the Conception. A picture by him representing Christ washing the feet of His disciples, is in the cathedral of Reims.

MWERU (or **MOERU**), a large lake of eastern central Africa. It lies 3,000 ft. above the sea, in a western branch of the great Tanganyika rift-valley. The lake is about 68 m. long by some 25 in breadth, and is roughly rectangular. It is cut a little south of its centre by 9° S. Mweru, first visited in 1798 by Dr. Lacerda, was reached by Livingstone in 1867, but its western shore was first explored in 1890 by Sir Alfred Sharpe, who two years later circumnavigated the lake. The eastern shores belong to Northern Rhodesia, the western to the Belgian Congo. The district is a game preserve and shooting is prohibited.

MYCENAE, one of the most ancient cities of Greece. The citadel on the summit is triangular with sides facing north, south-east and south-west. Part of the south-eastern wall and the palace within have been undermined by the torrent which bounds the lower town on the east. For the artistic significance of the various graves and building remains scattered among the groups of houses forming the lower town, see **AEGEAN CIVILIZATION**. Mycenae is a natural rock citadel standing in the north corner of the Argive plain flanked to north and south by deep ravines. It watched the hills, controlled the plain, and was the key to the road from the Gulf of Argos to the Gulf of Corinth which afforded the shortest route from Crete to central Greece.

The hill is roughly triangular with the apex pointing south and is defended by massive cyclopean walls. At the northwest angle is the Lion Gate surmounted by the famous limestone relief of two confronted lions ten feet high. The gate itself is about ten feet square and with its approaches is built of ashlar masonry in hard conglomerate. In the north wall is a smaller but similar gate and near it lies a secret underground cistern fed by the Perseian spring and approached by a subterranean passage from inside the walls. The extreme northeast angle is a later addition to strengthen this important point and to provide a sally port. Within the Lion Gate lies the Grave Circle enclosing the Royal Graves found by Schliemann and by it are ruined houses and storehouses. From the gate an inclined roadway leads to the summit crowned by the palace. This was built at different periods, but the ruins now visible belong in the main to the last great age of Mycenae. At the northwest angle was a columned entrance porch, and a throne room, a shrine, a bathroom, and a room with store jars have been found. On the south a wide staircase with two flights ascends to a spacious court. To the east a porch and vestibule open into the great hall (*megaron*) in the centre of which is a large circular hearth covered with painted stucco and surrounded by four column bases. The walls and floors of the *megaron*, court and vestibule were covered with painted stucco and there are plentiful remains of frescoes which adorned other rooms at different periods. West of the court a staircase led to the upper stories and to its north ran two parallel corridors giving access to other rooms at higher levels.

From the citadel a narrow ridge runs westwards so that its backbone forms the natural approach to the Lion Gate. Here are three of the beehive tombs (the Tomb of Aegisthus, the Lion Tomb, and the Tomb of Clytemnestra) and also the north wall of the Hellenistic lower town and the ruins of its gymnasium and theatre. At its west end a wider and longer ridge runs due south. Its northern

end was included in the Hellenistic lower town and somewhere along it must have run the prehistoric road. On its east side stands the Treasury of Atreus, the largest beehive tomb, and on its west another, and all about are rock cut chamber tombs. Below its southern extremity the ravine which runs from the south side of the citadel was spanned by a prehistoric bridge on the road leading southeast towards the Argive Heraeum and Tiryns. Sub-

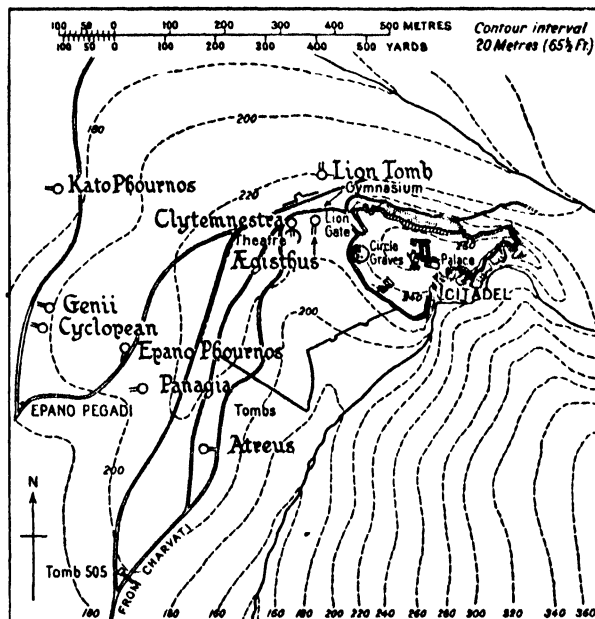

FIG. 1.—PLAN OF THE CITADEL OF MYCENAE

siidary ridges running westwards to the plain are also honey-combed with tombs among which are four more beehive tombs. On one ridge, Kalkani, traces of early Bronze Age occupation have come to light, and in the hollows are two ancient wells. On the peak of Hagios Elias which overlooks Mycenae to the north stands a small fort of the later part of the Third Bronze Age which clearly served as a signal station, for thence the whole plain can be surveyed from Asine to Argos with the passes towards Arcadia, Nemea and Cleonae and the Acrocorinth itself can be seen. A system of built roads radiates through the hills from Mycenae and they and the signal station emphasize its strategic and political importance.

Argolis was inhabited in the Neolithic age by a branch of the race that occupied central and northern Greece. No settlement of this period has yet been found at Mycenae, whose history begins with the Bronze Age. Then the citadel was occupied by the bronze using folk of the Early Aegean period who seem to have come into Greece from the islands and southwest Asia Minor. There is no clue to the language of the neolithic race, but the Bronze Age people probably spoke a non-Hellenic tongue and brought into Greece the place names which end in -nthos, -assos, or -ene. Among these is Mykene, a heroine mentioned by Homer whose name is to Mykenai as Athene is to Athenai. It is hard to estimate either the date of the Bronze Age settlement, which probably existed before the third millennium B.C., or its size, for ceramic remains, though frequent, are much disturbed by later buildings. With the beginning of the Middle Aegean period soon after 2200 B.C. a new racial element of unknown origin entered Greece. Its presence is marked by a class of pottery called Minyan Ware which has several varieties. The plentifulness of this and of a matt painted fabric, developed from the Early Bronze Age pottery at Mycenae, shows that the city prospered under this new impulse. As Minyan ware is practically unknown in Crete, though common in the islands, relations between Crete and Mycenae cannot have been intimate, and so the latter's expansion would have been mainly independent of Crete. Through-

out the Middle Bronze Age, on the hillside where the Grave Circle and Lion Gate were afterwards built, a cemetery had been in use, as this was the nearest spot where the rock was soft enough for simple cist graves of the type usual at the period. Among them in one special area larger and deeper graves were hewn out to contain the remains of the princes, the famous Shaft Graves, the treasures of which, excavated by Schliemann, first revealed the great prehistoric civilisation of Greece. The earliest, the Sixth, contains some objects from Crete, but the bulk of its pottery is unmistakably indigenous.

This Shaft Grave Dynasty rose to power about 1600 B.C. almost coinciding with the establishment of the 18th Dynasty in Egypt and the renaissance of Knossos after its destruction towards the end of the Middle Bronze Age. Slight signs of Cretan influence appear shortly before, but now at the beginning of the Late Bronze Age Cretan fashions and art were largely adopted at Mycenae. Three explanations are possible: (1) that Cretans now conquered the mainland and displacing the native population colonized a large portion; (2) that Mycenaean kings, strong on land and sea, successfully raided Crete, bringing home rich treasures and craftsmen as slaves; (3) that the kings of Mycenae grew powerful and rich, entered into relations with Crete and absorbed its culture. The first view seems least probable because for one reason Cretan pottery of the date of the alleged conquest is extremely rare at Mycenae where local fabrics still continued. Which of the other two is more correct time alone can show. The "Crétoiserie" of the Shaft Grave kings can be compared to the European *Chinoiserie* of the early 18th century, which was not the result of a Chinese conquest of Europe. These kings undoubtedly resided on the summit of the citadel where there are traces of a "palace" underlying the later palace. No signs of a circuit wall have yet been found and in any case it would not have had the area of the later enceinte. Still the richness of the royal graves and of private tombs of the period shows that a high standard of civilisation had been reached. This was not due entirely to the adoption of the Cretan culture, but to the fact that the newcomers of the Middle Bronze Age, who may well have spoken Greek, were themselves keen, energetic, and well advanced in things material, and needed only the contact with Crete to develop artistically as well.

Towards the close of the 16th century B.C. a change in royal burials indicates a new dynasty, which laid its princes in stone built beehive tombs from 25 to 50 feet in height and diameter. Nine such tombs exist at Mycenae. Their architecture displays gradual advance in technical matters, the use and cutting of materials and the handling of the problems of stresses and weights, so that they fall by progressive development into three groups of three tombs each. The first group belongs to the later 16th and to the early 15th century B.C. and the second group to the later 15th century. The earlier tombs were smaller, the construction primitive, the material inferior, the stone unshaped, and stresses not understood. The second group is larger and better built, the stone was hewn but not sawn, and a relieving triangle over the lintel was employed. In the two first groups the finest are the Tomb of Aegisthus and the Lion Tomb which last was closed with a door and threshold instead of rude stone walling. The first Beehive Tomb kings must have lived in the citadel but, apart from signs of their activity in the palace area, no other building can be definitely assigned to this date. The standard of culture was the same and there was intercourse with the islands, Crete and Egypt. The private tombs show that comfort was extending and the rather simple rock cut tombs of the 16th century now developed into spacious chambers with wide entrances.

After 1400 B.C. when Knossos fell and Egypt decayed under the last Amenhoteps, Mycenae, which had been rapidly developing since the end of the Middle Bronze Age, now took first place. Greek traditions, Homer's picture of Agamemnon as suzerain of the princes who sailed against Troy, and its mighty ruins, all bear witness to its greatness. Under the aegis of Mycenae ruled by the later kings of the Beehive Tomb Dynasty the Minoan-Mycenaean culture spread throughout the Eastern Mediterranean, and echoes of this are found in Homer. To this great age the

majority of the amazing buildings at Mycenae belong. The palace was reconstructed on a large and sumptuous scale, the cyclopean walls of the citadel were built with the Lion Gate. Within the walls rose storehouses and residences for the civil and military officers of the court, and for their guards and servants. The royal Shaft Graves with part of the old cemetery were enclosed within the enceinte and the space round them was levelled, ringed with standing slabs, and made into a sacred area for the worship of the dead princes.

These later kings of the Beehive Tomb Dynasty to whose energy and ability the greatness of Mycenae seems so largely due, were buried in the last group of Beehive Tombs, the Treasury of Atreus, the Tomb of Clytemnestra, and the Tomb of Genii. These are naturally the best in construction, plan and size, and are built throughout of hard stone, mainly sawn. Each had a door, and a threshold constructed on a wedge principle. The understanding of stresses and of the means to counteract them shows that their architects profiting by earlier experiments perfected their methods and materials, so that two of these tombs still stand almost intact. The Treasury of Atreus is structurally so like the Lion Gate and the palace that it is possible that the royal builder of the two latter prepared the former as his tomb. The same style occurs in the walls and palace at Tiryns which are contemporary. The civilian population of Mycenae must have lived in undefended settlements on the neighbouring hills and the many cemeteries of this date divide into local groups suggesting separate communities. The tombs are carefully hewn in the rock with long narrow entrance passages and were furnished with objects in pottery, bronze, glass, ivory and gold, which show that the culture of Mycenae at its zenith even if less artistic displays wonderful technical ability. During the 14th and 13th centuries B.C. at Mycenae not only were crafts such as the potter's intensively and skilfully practised, but also professions such as those of engineers and architects, for the cyclopean walls and great domes like the Treasury of Atreus imply structural genius.

Troy according to tradition was taken early in the 12th century. Then, as the use of iron spread, the Iron Age began and as the contemporary Egyptian records say "the Isles were restless." This was the age of the Dorian Migration. Then Mycenae fell and the palace and houses were burnt. The walls, however, were not destroyed and as such a stronghold could not be left untenanted Mycenae was inhabited during the early Iron Age, but was of small importance as Dorian Argos usurped her place. As a small city state it preserved its independence and a Doric temple of Athena who ousted the local heroine Mykene arose early in the sixth century upon the ruins of the palace of the Bronze Age kings. Some sculptures from this temple survive. The debris among the ruins proves Mycenae's continuous existence, through the geometric, orientalisising and archaic periods of Greek art down to the Persian Wars. Then Mycenae sent her small contingent to join in resisting Xerxes' invasion. Her men fought at Plataea in 479 B.C. and the name *Μυκηνῆς* can still be read on the serpent column from Delphi now in the Hippodrome at Constantinople. Argive jealousy, however, could not forgive and in 470 B.C. when Sparta was in difficulties an Argive army besieged Mycenae. The citadel was starved out, its walls and buildings were overthrown and the site laid waste.

In 235 B.C. the Argive tyrant Aristippos was murdered at Mycenae which like other small towns dependent on Argos was probably reoccupied by the Argive tyrants of the third century B.C. during their struggles with the Achaean League. The walls of the citadel were repaired and part of the hillside on the south was walled in to make a lower town. In this lay a small theatre directly above the Tomb of Clytemnestra and by it was a gymnasium. The Doric temple, which the Argives had perhaps spared in 470 B.C., still stood on the summit of the citadel. Inscriptions dating probably from 194 B.C. and referring to Mycenae's relations with Argos and Nabis of Sparta give some details of its government. After Argos was freed from Nabis Mycenae vanishes from history and Pausanias in the second century A.D. makes no mention of inhabitation. A few remains of the Roman period have been

found so it cannot have been entirely deserted, but the depopulation of Greece must have affected Mycenae and a few inhabitants among ruins so famous would give every impression of desolation. Soon after it must have been completely deserted, for there are no traces of Byzantine or later occupation.

The site of Mycenae was never forgotten as Pausanias who saw the Lion Gate shows and when Greece began to be revisited by travellers from western Europe it became a place of pilgrimage. Excavations were begun by Schliemann who made soundings in 1873, but conducted his epoch-making campaign in 1876 when he found the royal Shaft Graves. Stamatakes followed from 1877 to 1879 when he found the sixth Shaft Grave and cleared the Treasury of Atreus. From 1886 to 1902 Tsountas in a fruitful series of excavations cleared several houses, and found the palace, three beehive tombs, and a large number of private tombs. Rodenwaldt did valuable work on the frescoes in the palace between 1912 and 1914. From 1920 to 1923 Wace excavated here for the British School at Athens, when many tombs were found and new and important results were obtained from the Grave Circle, the Beehive Tombs and the palace.

MYCETOZOA (slime-fungi), low organisms (often classed with fungi, but undoubtedly more nearly related to the protozoa), of which the individuals (plasmodia) are essentially nothing but giant amoebae. In unfavourable conditions of life, such as hunger or drought, the plasmodia become changed into fructifications (usually stalked capsules, filled with numerous unicellular spores), which bear a close resemblance to the fructifications of some fungi. For further particulars see **PROTOZOA**.

MYCOLOGY is the science of fungi (Greek *μύκης*, a mushroom, *μολός*, discourse), and is dealt with in the article **FUNGUS**.

MYCONIUS, FRIEDRICH (1490–1546), Lutheran divine, was born on Dec. 26, 1490, at Lichtenfels on the Main, of worthy and pious parents, whose family name was Mecum. While a student at Annaberg, he had a memorable encounter with the Dominican, Tetzl, his point being that indulgences should be given *pauperibus gratis*. His teacher, Staffelstein, persuaded him to enter (1510) the Franciscan cloister. From Annaberg he passed to Franciscan communities at Leipzig and Weimar, where he was ordained priest (1516), and next year his “eyes and ears were opened” by the theses of Luther. For six years he preached his new gospel, under difficulties, in various seats of his order, lastly at Zwickau, whence he was called to Gotha (1524) by Duke John at the general desire. Here he married Margaret Jäcken. He had Luther's confidence, and was twice entrusted (1528 and 1533) with the ordering of the churches and schools in Thuringia. At the Convention of Schmalkalden he signed the articles on his own behalf and that of his friend Justus Menius. In 1538 he was in England, as theologian to the embassy which hoped to induce Henry VIII. to make common cause with the Lutheran reformation on the basis of the Augsburg Confession, a project which Myconius caustically observed might prosper if Henry were allowed to be pope. He died on April 7, 1546.

His *Historia reformationis*, referring especially to Gotha, was not printed till 1715. See Melchior Adam, *Vitae theologorum* (1706); J. G. Bosseck, *F. Myconii Memoriam* . . . (1739); C. K. G. Lommatzsch, *Narratio de F. Myconio* (1825); K. F. Ledderhose, *F. Myconius* (1854).

MYCORRHIZA. The roots of land plants live in soil, competing therein for water and nutrients with a crowded population of micro-organisms. They are surrounded by a rich and varied fungus flora many members of which are potential parasites, but

the majority of roots are relatively immune to such parasitic attack and continue to flourish side by side with their fungus competitors. To the interaction of these three phenomena—the competitive struggle for food, the capacity of many fungi to penetrate living tissues and the properties of resistance to such invasion possessed by roots in common with organisms in general—is probably due the evolution of *mycorrhiza*, that curious and interesting partnership between the roots of vascular plants and fungus mycelium now known to affect a vast number of the higher plants and to be of great importance in their lives.

Mycorrhizae or fungus-roots (*μύκης*, a mushroom) (*ρίζα*, a root) are formed alike by wild and cultivated plants, by species from the high mountains and by those from salt marshes at sea level, in the vegetation of tropical forests as in that within the arctic circle. The phenomenon was comparatively well-known, especially to foresters when, in 1885, the German botanist, Frank, coined the new name, ‘mycorrhiza,’ to register his own view that the root with its associated mycelium constituted an independent organ of great importance in plant nutrition. He reported an invariable and intimate association of fungus mycelium with the roots of forest trees, especially oak, beech, hornbeam and other members of Cupuliferae, and certain conifers, such infection being, in his opinion, not parasitic but of definite service to the trees in relation to the absorption of water and nutrient salts. On a contemporary view associated especially with the name of Robert Hartig, the root fungi of trees were mischievous parasites hindering root action and conferring no benefit upon the hosts.

By the end of the nineteenth century it was realized by botanists that the mycorrhizal habit was widespread, affecting not only trees but an immense number of herbaceous species belonging to different families.

Distribution and Structure.—Mycorrhiza is formed by ferns, club mosses, conifers and an ever growing list of flowering plants belonging to many different families. It is constant and conspicuous in certain groups, e.g., Orchidaceae, Ericales, Empetraceae and forest trees generally, and is invariably well developed in species lacking chlorophyll, e.g., *Neottia Nidus-avis*, *Corallorhiza* spp. and a number of tropical orchids belonging to this class, members of the Monotropoideae, and certain species belonging to the families Gentianaceae and Burmanniaceae. Structures closely resembling the mycorrhizal tissues of living species have been described in fossils of Coal Measure age. It is specially characteristic of the vegetation of humus soils, viz., those of moorlands, woodlands and heaths, but may be well developed in garden soil and in the most diverse situations elsewhere. It may be regarded as an annual phenomenon affecting all or a proportion only of the young absorbing roots of the current year.

It is assumed that the fungi concerned are widely distributed in soil, and with few exceptions invasion of the roots takes place from this source. The effect of infection is strikingly different from that in ordinary parasitism, there being no indication that the tissues suffer any permanent injury from the more or less extensive infestation by mycelium to which they are subjected. The external appearance of the root may be altered, as in trees, where arrest of growth accompanied by profuse branching results in the production of dense clusters of rootlets, brown or variously coloured according to the kind of mycelium present. Sometimes the appearance of the roots is not altered in any way. There is great variation in different plants and at different seasons in respect to the relative abundance of mycelium, its distribution upon and within roots and the details of structure of individual mycorrhizas.

It is still convenient to recognize two main types of structure and use the descriptive names given to them by Frank in 1885; the *ectotrophic* type, specially characteristic of trees, in which mycelium completely invests the tip and younger portion of the root as with a sheath of varying thickness, branches from which penetrate between the cortical cells to form a continuous network, while individual cells remain relatively immune from infection; and the *endotrophic* type, showing a variable amount of mycelium externally without formation of a sheath, combined with a more or less profuse distribution of hyphae within the

cells, sometimes irregularly distributed in the cortical tissues, sometimes localized in definite zones. The individual cells that suffer invasion become filled with coiled or branched hyphae continuous with those which form an irregular mesh upon the external surface of the root and permeate the soil around it. In a majority of fungus-roots these intracellular hyphal complexes disintegrate, dwindle and disappear, the soluble by-products presumably passing to the host cells.

These two types of mycorrhiza are not sharply distinguished from one another as Frank believed. It is known now that those of the ectotrophic type often exhibit relatively heavy infection of individual cells, and it seems probable that the structural differences are related to the character of the mycelium and to soil conditions rather than to any fundamental distinction in the association as a whole.

The Mycorrhiza of Orchids.—The mycorrhiza of orchids is of the endotrophic type and mycelium may be widely distributed throughout the root cortex or confined to certain regions. Two contrasting types of cell are observable: *Pilzwurthzellen* or "host cells," containing active hyphae, and *Verdauungszellen* or "digestion-cells," enclosing only their disintegrated remains subsequent to digestion. In the former the mycelium fills the cells with skeins or "pelotons" of characteristic appearance and probably abstracts nutrient materials from the host; in the latter these substances and possibly others brought in from the soil are placed at the disposal of the root.

The researches of a French botanist, Bernard, initiated a new method of experimental inquiry and demonstrated the far-reaching character of the relationship in orchids. The difficulties experienced by growers in germinating seeds of orchids had long been known. Bernard isolated the root fungi from a number of species and showed, by "pure culture" methods, that germination of seed and development of the seedling are bound up with infection by the appropriate root fungus at a critical stage of development. In nature, this *symbiotic* type of germination is ensured by the presence of mycelium of the root fungus in the soil about the roots of the parent plant; in horticultural practice, artificial cultures have been successfully utilized by L. Knudson for the same purpose. It has been discovered that the stimulus normally provided by the appropriate fungus can be replaced artificially by carefully adjusting the chemical constitution and reaction of the seedbed, and such *asymbiotic* methods of securing germination have been successfully applied by horticulturalists in the case of certain orchid species.

There remains much that is obscure in the relation of fungus and host in this group of plants. The nature of the problems awaiting solution is sufficiently indicated by the invariable association of particular fungus strains with individual orchid species, and by the fact that orchid growing is concerned not only with the cultivation of natural species but with the raising of new hybrids.

Mycorrhiza in Ericaceae.—In northern Europe certain members of the family Ericaceae, e.g., various kinds of heath (*Erica* spp.), and heather or ling (*Calluna vulgaris*) are a constant feature of the vegetation of humus soils—moorland and woodland—on which they often monopolize large areas to the almost complete exclusion of other plants.

Described by Frank as *obligate mycorrhiza plants*, it was early recognized that members of this group might exhibit specialized relations with their root fungi. The mycorrhiza is of the endotrophic type with certain characteristic features, in some respects showing points of resemblance with that of trees. The young roots are excessively fine, the outermost layer of cells in each forming a definite mycorrhizal zone. In favourable soil conditions practically every cell in this layer is filled with a densely branched complex of fungal hyphae from which strands of mycelium extend outwards into the soil. The growth of mycelium on the outside of the roots is rather more profuse than in orchids, and, in certain species, may resemble the sheath-like condition found in ectotrophic mycorrhizas. As in orchids, the complexes of mycelium within the root cells are subject to rapid and complete digestion followed by disappearance of the resulting products.

In ling (*Calluna vulgaris*) and certain allied species an *obligate* relation unique of its kind has been revealed by experimental research. In these plants the mycelium which infests the root spreads throughout the tissues of the vegetative shoots, flowers and fruits reaching eventually the seed-coats of the developing seeds. These are shed bearing with them the mycelium of the fungus partner and at germination the emerging seedling is immediately subject to invasion.

The distribution of mycelium throughout the plant thus compares sharply with that found in orchids where it is limited to the roots of the adult and the embryonic tissues of the seedling. In *Calluna* and kindred ericaceous species it is practically co-extensive with the plant tissues. Only the embryo and endosperm of the resting seed are free from contamination; at all other stages of development and throughout its vegetative existence every plant of ling yet examined is a dual organism. In the genus *Vaccinium* the intimacy of the relation has been carried a stage farther and mycelium is present, not only externally upon the seed-coats, but internally throughout the tissues of the seed. The mode of infection observed in Ericaceae is unique, for, in all other known cases, the mycelium responsible for forming mycorrhiza enters the root from the soil.

In ling and probably in allied species the formation of functional mycorrhiza is closely related to soil conditions. It is at a maximum in peaty soils and in cultivated soils with abundant humus, much less conspicuous in sandy soils deficient in organic matter, and may appear to be absent under certain conditions, although roots are never free from fungus infection.

Since seedling development follows and depends upon invasion by fungus mycelium at germination, it is impossible to provide experimental evidence bearing on the behaviour of individuals with and without fungus infection.

The Mycorrhiza of Trees.—The mycorrhiza of trees is characteristic and easily recognized. Structurally, it belongs to the ectotrophic type; each rootlet is enveloped in a sheath of mycelium formed by the close interweaving of hyphae continuous internally with a branch system penetrating between the cells of the roots, externally with the network of mycelium in the soil.

Woodland soils possess an unusually rich and varied fungus flora among which members of the great group known as Hymenomycetes are conspicuous, as evidenced by the profusion of their spore-bodies—toadstools—produced during suitable seasons. So constant is the association of some of these with certain trees that it has been said that they follow the latter "as the dolphin follows the ship."

In order to prove a direct relation between these common woodland fungi and the mycorrhiza of the trees beneath which they grow, it was necessary to isolate the endophytes, learn something of their behaviour and compare the growth of young trees with and without mycorrhiza. By such means a number of Hymenomycetes have been identified as the specific root fungi of pine, spruce, larch, birch and other trees.

There is no evidence that seedling development is bound up with fungus infection or that anything in the nature of an *obligate* relation exists. As regards the effect of tree mycorrhiza on nutrition, it must be noted that woodland soils possess certain definite characteristics. There is severe competition for water and salts and they show a notable deficiency of certain plant nutrients, in particular nitrates. On the other hand, they possess large reserves of nitrogen in the form of organic compounds. It has been proved experimentally that the possession of mycorrhiza is beneficial to trees, especially in relation to the supply of nitrogenous nutrients. Hence, the supply of nitrates being deficient it may be concluded that it possesses a vital significance for trees and other plants growing in woodland soils. The application of these conclusions to natural conditions raises problems of great importance to practical foresters.

Identity of Mycorrhizal Fungi.—It may be assumed that the fungi responsible for forming mycorrhiza are widely distributed in soil. Their systematic position is known only in those forms which have been isolated and grown in "pure culture" out-

side the root.

The root fungi of orchids are generally recognized as belonging to a common group, sometimes included in the well-known genus *Rhizoctonia*, sometimes placed in a new genus *Orcheomyces*. The mycelium must be locally present about the roots of wild orchids but nothing is known as to its wider distribution.

The mycorrhizal fungi of *Calluna* and other ericaceous species have been isolated and included in a single species of the genus *Phoma*, *P. radialis*. The specialized strains associated with different ericaceous species are distinct and must be locally distributed in heath and moorland soils but there is no certain knowledge of their wider occurrence.

The fungi definitely identified with the mycorrhiza of trees belong to the genera *Boletus*, *Amanita*, *Cortinarius*, *Lactarius*, *Russula* and *Tricholoma*. It is probable that many others will prove to belong to the same category.

Outside these specialized groups, the fungi responsible for mycorrhiza-formation still await identification. The mycelium present in a large number of herbaceous flowering plants, certain ferns and club mosses is uniform in type and produces characteristic structures: round or pear-shaped swellings or *vesicles*, variously regarded as organs relating to spore-formation or to the storage of reserves, and intracellular branch systems first described by Gallaud in 1905 under the name of *arbuscules*. Following upon digestive activity in the host cells the latter disintegrate to structureless masses named *sporangioides* before their true nature is recognized. The fungus responsible for this widespread type of mycorrhiza has hitherto resisted all attempts at isolation and nothing is known with certainty as to its systematic position.

• It has been reported that the mycorrhiza of many herbaceous plants is of dual character, involving primary infection by a fungus with the characters just described followed by secondary infection by one of the type associated with orchid roots. Whether this reported "double infection" is of biological significance is at present unknown.

Role of Mycorrhiza in Plant Growth.—There can be little doubt that the mycorrhizal habit had its origin in parasitic attack on the part of certain soil fungi, or that existing mycorrhiza plants are the survivors of a long and perilous evolutionary history. Many must be regarded as cases of compromise fluctuating between an almost complete resistance to fungus invasion and a remarkable toleration of the same. That there is an exchange of nutrient material in practically all cases can hardly be doubted but, in the absence of information based on the behaviour of individuals with and without mycorrhiza, attempts to express the shifting relationships in terms of mutual advantage or the reverse are premature and often misleading.

In certain groups of plants mycorrhiza has become a regular feature in the life history, a condition of delicately balanced equilibrium between fungus and host has been established and critical experimental study has placed certain facts beyond doubt. In both orchids and heaths the normal development of the seedling is bound up with the presence and activities of mycorrhizal fungi showing marked adaptation to individual species, accompanied in members of Ericaceae by a distribution of mycelium throughout the tissues so extensive that it is difficult to conceive of the individual plant as other than a single entity of double constitution. In orchids, the traditional view attributes a beneficial rôle to the root fungi based on their utilization of organic soil constituents and the wholesale digestion of mycelium that takes place subsequently in the root-cells. A claim has been advanced for fixation of atmospheric nitrogen by the root fungi of several orchid species.

It may be safely concluded that mycorrhiza possesses a vital significance for trees and other plants growing in woodland soils, and there is reason to believe that the reaction and constitution of the soil are important factors in promoting its healthy development and functioning. In the Ericaceae, *Calluna* and many of its allies are characteristic and abundant members of the vegetation of humus soils thus pointing to similar conclusions, while in this group there is likewise evidence that the capacity to draw directly upon the organic compounds in the soil humus is sup-

plemented by the ability of the root fungi to utilize atmospheric nitrogen. In both orchids and heaths the obligate character of the association is probably confined to the seedling phase and does not extend to the adult, although in heaths infection of the roots follows directly upon that of the seedling tissues.

The older theories of beneficial symbioses in mycorrhiza were deduced from distribution and structure untested by experiment. Modern research has been marked by the application of new and more precise methods and has revealed unsuspected relationships. On the whole, it supports the view that the possession of mycorrhiza is frequently of service to vascular plants, the nature and degree of benefit depending upon the physical conditions of the environment and the character of the association in individual cases. (M. C. R.)

Melin, *Untersuchung über die Bedeutung der Baummycorrhiza* (Jena, 1925); L. Knudson, "Physiological Study of the Symbiotic Germination of Orchid Seeds," *Bot. Gaz.*, vol. lxxix, pp. 345-379.

MYDDELTON or MIDDLETON, SIR HUGH, 1ST BART., cr. 1622 (c. 1560-1631), was born a younger son of Sir Richard Myddelton, governor of Denbigh castle. Hugh was a successful London goldsmith, occupying a shop in Bassihaw, or Basinghall street; he made money by commercial ventures on the Spanish main, being associated in these with Sir Walter Raleigh; and he was also interested in cloth-making. He was an alderman, and then recorder of Denbigh, and was member of parliament for this borough from 1603 to 1628. In 1609 Myddelton took over from the corporation of London the projected scheme for supplying the city with water obtained from springs near Ware, in Hertfordshire. For this purpose he made a canal about 10 ft. wide and 4 ft. deep and over 38 m. in length, which discharged its waters into a reservoir at Islington called the New River Head. The work was completed in 1613. Myddelton also worked lead and silver mines in Cardiganshire and reclaimed a piece of the Isle of Wight from the sea. He died on Dec. 10, 1631, and was buried at St. Matthew's, Friday street, London.

MYELITIS. A medical term for destructive changes involving the spinal cord. As the termination "itis" indicates, these changes formerly were regarded as inflammatory, but it is now known that although the spinal meninges are affected by inflammation, nervous substance is rarely, if ever, "inflamed" because of its paucity of blood-vessels. On the other hand, its nutrition is readily impaired by morbid processes in its neighbourhood, and it degenerates or dies and undergoes softening. Myelitis is such softening of the spinal cord, local or widespread, affecting a portion of the cord or its whole thickness, and the symptoms to which it gives rise depend upon the site and extent of the lesion. It may run a rapid or a chronic course, and in the latter instance the degenerated nerve substance may be, in whole or in part, replaced by proliferated neuroglial tissue which is of the nature of a scar. Any part of the cord may be affected, but it is commoner in the lower half. It leads to paralysis of lower limbs and other muscular parts by interference with conductivity in the white matter of the cord, and to nutritive changes by destruction of the cells in the grey matter. It causes loss of sensation below the level of damage, and often a zone of hyperaesthesia just above that level. If acute it is often followed with great rapidity by bed sores of great size and depth, and incontinence of urine and faeces, particularly when the lumbar cord is affected. The chief causes are injuries and diseases of the vertebrae or meninges leading to pressure on the cord, particularly syphilis. The disease principally affects adults. As might be anticipated, treatment is unsatisfactory and is directed towards relief of symptoms. (W. S. L.-B.)

MYERS, FREDERIC WILLIAM HENRY (1843-1901), English poet and essayist, son of Frederic Myers, was born at Keswick, Cumberland, on Feb. 6, 1843, and educated at Cheltenham and Trinity college, Cambridge, where he was

appointed classical lecturer in 1865. He had no love for teaching, which he soon discontinued, but he took up his permanent abode at Cambridge in 1872, when he became a school inspector under the education department. He published poems, for instance *St. Paul*, but is more likely to be remembered by his *Essays, Classical and Modern* (2 vols., 1883). The essay on Virgil, by far the best thing he ever wrote, represents the matured enthusiasm of a student and a disciple to whom the exquisite artificiality and refined culture of Virgil's method were profoundly congenial. In 1882 Myers led a small band of explorers (including Henry Sidgwick and Richard Hodgson, Edmund Gurney and F. Podmore), who founded the Society for Psychical Research. He was the mouthpiece of the society, and steered a middle course between extremes. He helped to revise the cumbrous mass of *Proceedings*, the chief concrete results being the two volumes of *Phantasms of the Living* (1886). His *Human Personality and its Survival of Bodily Death* (2 vols. 1903) was described by William James as "the first attempt to consider the phenomena of hallucination, hypnotism, automatism, double personality and mediumship, as connected parts of one whole subject." Also there was *Science and a Future Life* (1893). He died at Rome on Jan. 17, 1901, but was buried in his native soil at Keswick.

MYLIUS-ERICHSEN, LUDWIG (1872-1907), Danish explorer, was born at Viborg, Jutland, on Jan. 15, 1872. He made two notable expeditions to Greenland in 1902-04 and in 1906. The first of these yielded much valuable ethnographical information; the second provided increased geographical knowledge of the eastern coast. The explorer died as a result of the hardships he had suffered, on Nov. 25, 1907.

MYLODON, an extinct genus of large ground-sloths characteristic of the Pleistocene of the New World. The animal was of the size of a rhinoceros, with short stout limbs, very large digging claws, five digits on each foot, but the outer ones have no claws, a broad body and massive tail. It walked on the outer edge of the sole, both fore- and hind-foot (compare fore-foot of

SKELTON OF THE MYLODON ROBUSTUS (PLEISTOCENE, SOUTH AMERICA)

modern ant-eater). The head was rather long, with wide blunt muzzle, no front teeth, and moderately large prismatic cheek teeth, five above and four below on each side. In cross-section the more anterior teeth are rounded oval, while the posterior ones are progressively larger and more elaborate, the last molar always two- or three-lobed. The skin was probably like that of the allied genus *Grypotherium* in which, as shown by specimens from a cave off the Straits of Magellan, the skin was studded with bony ossicles and covered with heavy coarse brown hair.

The genus *Mylodon* (in the wider sense) ranged from Canada

to Patagonia, and many complete skeletons have been found in Argentina, California and the central United States. A number of related genera are also found in the Pleistocene of South America. *Lestodon* has the front pair of teeth enlarged as tusks and a flaring, bell-shaped muzzle. *Scelidotherium* has a much more elongate skull, narrower body and more reduction and specialization in the toes. These with some other less known genera form the family Mylodontidae, whose ancestry can be traced back to the Miocene in Patagonia although not so well known as the related Megatheriidae. These small Miocene ground-sloths come near to being ancestors of the modern tree-sloths as well; they likewise approach the ant-eaters in various particulars and suggest a more remote affinity to the armadillos.

(W. D. M.)

MYLONITE, in petrology, a rock which has been crushed and ground down by earth movement and at the same time rendered compact by pressure. Mylonites are fine-grained, sometimes even flinty, in appearance, and often banded in parallel fashion with stripes of varying composition. The great majority are quartzose rocks, such as quartzite and quartz-schist; but in almost any type of rock mylonitic structure may be developed. Gneisses of various kinds, hornblende-schists, chlorite-schists and limestones are not infrequently found in belts of mylonitic rock. The process of crushing by which mylonites are formed is known also as "granulitization" and "cataclasis," and mylonites are often described as granulites, though the two terms are not strictly equivalent in all their applications. Mylonites occur in regions where there have been intense earth-movements. Thrust planes and great reversed faults are often bounded by rocks which have all been crushed to fine slabby mylonites, that split readily along planes parallel to the direction in which movement has taken place. These "crush-belts" may be only a few feet or several hundred yards broad. The movements have probably taken place slowly without great rise of temperature, and hence the rocks have not recrystallized to any extent.

MYMENSINGH, a town and district of British India, in the Dacca division of Bengal. The town (formerly known as Nasirabad) is situated on an old channel of the Brahmaputra, and has a station of the Eastern Bengal State railway. Pop. (1921) 25,287. The District of Mymensingh, with an area of 6,238 sq.m. and a population (1921) of 4,837,730, is the largest district in India, and its administration is an onerous charge. It occupies a portion of the alluvial valley of the Brahmaputra east of the main channel (called the Jamuna) and north of Dacca, for the most part level and open, covered with well-cultivated fields, and intersected by numerous rivers. The Madhupur jungle is a slightly elevated tract, extending from the north of Dacca district into the heart of Mymensingh; its average height is about 60 ft. above the level of the surrounding country, and it nowhere exceeds 100 feet. This tract divides Mymensingh into two distinct parts. On the west is an alluvial plain watered by the Jamuna; the eastern area is fertilized by the Surma or Meghna, the old Brahmaputra and other streams, and contains extensive marshes, which are under water for eight months in the year and are grazing grounds for cattle for the other four months. The only other elevated tract in the district is on the southern border, where the Susang hills rise. The Jamuna forms the western boundary for a course of 94 m.; during the rainy season it expands in many places to 5 or 6 m. in breadth. The Brahmaputra formerly flowed through Mymensingh till it joined the Meghna a little below Bhairab Bazar, but over a century ago the formation of bars of sand in the upper part of its course diverted the main volume of water into the present channel of the Jamuna. The staple crop is rice. A branch line of the Eastern Bengal State railway runs north from Dacca through Mymensingh, which is also connected with Jagannathganj and Bhairab Bazar.

MYNAH, the name given to several birds of the starling family (*Sturnidae*). The Indian house mynah (*Acridotheres tristis*) is a well-known bird in the East and has been introduced into Australia and New Zealand. Somewhat larger than a thrush, with brown plumage, except for a black head and white on the wings and tail, the house mynah is easily domesticated and will

learn to talk. The true talking mynah (*Gracula religiosa*) is, however, a very different bird (See GRACKLE).

MYNN, ALFRED (1807–1861), perhaps the greatest of the older cricketers, was born at Goudhurst, in Kent, on Jan. 19, 1807, and died in London on Nov. 1, 1861. A huge man, standing 6 ft. 1 in. and weighing 18 to 20 stone, he was an all-round cricketer, but it is on his bowling that contemporary records lay most stress. "His delivery was noble, walking majestically up to the crease," and his bowling came so sharply in from leg that there is reason to suppose he may have been one of the first to practise the swerve. Two outstanding incidents in his career may be noted. Before the return North v. South match at Leicester, in 1836, he was hurt in practice. Going in to bat, he made 146, when he had to retire in great pain. He was hurried to London, and nearly had to have his leg amputated. In 1838 he won two great matches for the championship of England at single wicket, at which he was never beaten, against Dearman of Sheffield. There are many portraits of Mynn; the best known is in the picture of the All England XI. of 1847. No other cricketer, except "W.G." himself, ever captured so completely by his prowess and personality the hearts of his generation; his epitaph, which appeared in *Bell's Life*, is one of the most famous pieces of cricket literature. It begins with the echo of an old controversy:

Jackson's pace is very fearful, Willsher's hand is very high and ends

as the changing seasons pass,

As our champion lies a-sleeping underneath the Kentish grass,
Proudly, sadly we will name him, to forget him were a sin;
Lightly lie the turf upon thee—kind and manly Alfred Mynn

See *Scores and Biographies*, vol. ii. (1861); R. Daft, *Kings of Cricket* (1893); H. S. Altham, *History of Cricket* (1926).

MYRA (mod. *Dembre*), an ancient town of Lycia situated a short distance inland between the rivers Myrus and Andracus. Its early history is obscure. St. Paul touched Myra on his last journey westward, and changed into "a ship of Alexandria sailing into Italy." In the 3rd century St. Nicholas, of Patara, was its bishop. Theodosius II. made Myra the Byzantine capital of Lycia, and as such it was besieged and taken by Harun al-Rashid in 808. The town seems shortly afterwards to have decayed. A small Turkish village occupied the plain at the foot of the acropolis, and a little Greek monastery lay about a mile westward by the church of St. Nicholas. The latter has formed the nucleus of modern Dembre. The western scarp of the acropolis has been sculptured into a number of sepulchres imitating wooden houses with pillared façades, some of which have pediment reliefs and inscriptions in Lycian. The theatre lies at the foot of this cliff and is partly excavated out of it, partly built. The church of St. Nicholas lies out in the plain, at the western end of Dembre. Its floor is far below the present level of the plain, and until recently the church was half filled with earth. The ancient church is of the domed basilica form with throne and seats still existent in the tribunal. There are also extensive ruins of Andriaca, the port of Myra, about 3 m. west, containing churches, baths, and a great grain store, inscribed with Hadrian's name. They lie along the course of the Andraki river, whose navigable estuary is still fringed with ruined quays.

MYRIAPODA, a convenient name for four classes of arthropods often studied together:—Diplopoda (Millipedes, *q.v.*), Symphyla (*q.v.*), Pauropoda (*q.v.*), and Chilopoda (Centipedes, *q.v.*). There is a superficial resemblance about all four classes because all possess a distinct head provided with one pair of antennae and an undivided trunk bearing a large number of jointed limbs, but the resemblance is deceptive and the grouping unscientific because the centipedes are more nearly related to insects than they are to the other three classes.

MYRICA, in botany, the only genus of the family Myricaceae, perhaps most nearly allied to the willows and birches. There are about 45 species widely distributed throughout the world. Well known representatives are the sweet gale and wax-myrtle (*q.v.*).

MYRISTICACEAE, in botany, the nutmeg family, comprising 18 genera and 275 species, all tropical and especially numerous in Asia. They are trees or shrubs with evergreen leaves. (See NUTMEG.)

MYRMIDONES, in Homer, the inhabitants of Phthiotis in Thessaly. According to posthomeric legends their original home was Aegina, whence they crossed over to Thessaly with Peleus, but the converse view is now more generally accepted. Their name is derived from a supposed ancestor, son of Zeus and Eurymedusa, who was wooed by the god in the form of an ant (*Gr. μύρμηξ*); or from the repopling of Aegina (when all its inhabitants had died of the plague) with ants changed into men by Zeus at the prayer of Aeacus, king of the island. As the fierce and devoted followers of Achilles, their name has come to be used in modern times to mean subordinates who carry out orders implacably. (See Roscher's *Lexikon*, art. Myrmidon.)

MYROBALANS, the name given to the astringent fruits of several species of *Terminalia*, largely used in India for dyeing and tanning and exported for the same purpose. They are large deciduous trees of the family Combretaceae. The chief kinds are the chebulic or black myrobalan, from *Terminalia Chebula*, which are smooth, and the beleric, from *T. belerica*, which are five-angled and covered with greyish down.

MYRRH, a gum-resin (see RESINS), highly esteemed by the ancients as an unguent and perfume, used for incense in temples and also in embalming; it was one of the gifts offered by the Magi. True myrrh is the product of *Commiphora Myrrha*, a small tree of the family Burseraceae that grows in eastern Africa and Arabia, but the name is also applied to gum-resins obtained from other species of *Commiphora*.

Baisa Bol, *Bhesa Bol* or *Bissa Bol*, from *Commiphora Kataf*, resembles true myrrh in appearance, but has a disagreeable taste and is scarcely bitter. It is used in China, mixed with food, to give to cows to improve the quality and increase the quantity of milk, and when mixed with lime as a size to impart a gloss to walls. Opaque bdellium produced by *C. Playfairii*, when shaken with water forms a slight but permanent lather. It is known as *meena hārma* in Bombay, and was formerly used there for the expulsion of the guinea-worm. African bdellium is from *C. africana*, and like opaque bdellium lacks the white streaks which are characteristic of myrrh and bissa bol; both are acrid, but have scarcely any bitterness or aroma. Indian bdellium, probably identical with the Indian drug googol obtained in Sind and Baluchistan from *C. Mukul* and *C. pubescens*, Hook, is of a dark reddish colour, has an acrid taste and an odour resembling cedar-wood, and softens in the hand.

As met in commerce true myrrh occurs in pieces of irregular size and shape, from ½ in. to 2 or 3 in. in diameter, and of a reddish-brown colour. The transverse fracture has a resinous appearance with white streaks; the flavour is bitter and aromatic, and the odour characteristic. It consists of a mixture of resin, gum and essential oil, the resin being present to the extent of 25 to 40%, with 2½ to 8% of the oil, myrrhol, to which the odour is due.

MYRTACEAE, in botany, the myrtle or eucalyptus family, dicotyledonous trees and shrubs found in all the warmer parts of the world, especially in Australia and tropical America. There are about 90 genera and some 2,800 species, all with oil-glands in the evergreen leaves. Several species yield useful timber, and *Eucalyptus* also gives oil; *Eugenia*, cloves, etc. Some have edible fruits, as *Psidium* (guava), *Rhodomyrtus* (hill-gooseberry) and *Feijoa* (pineapple guava). *Pimenta officinalis* yields allspice (*q.v.*) and *P. acris*, bay oil. (See EUCALYPTUS; FEIJOA; GUAVA.)

MYRTLE, the *Myrtus communis*, of botanists, as now found growing wild in many parts of the Mediterranean region. It is a low-growing, evergreen shrub, with opposite leaves, varying in size, but always small, simple, dark-green, thick in texture, and studded with numerous receptacles for oil. When the leaf is held up to the light it appears as if perforated with pin-holes owing to the translucency of these oil-cysts. The fragrance of the plant depends upon the presence of this oil. Another peculiarity of the myrtle is the existence of a prominent vein running round the leaf within the margin. The flowers are borne on short stalks in the axils of the leaves. The fruit is a purplish berry, enclosing very numerous minute seeds. Many varieties are in cultivation. The typical species is quite hardy in the south of England. The Chilean species, *M. Ugni*, a shrub with ovate, dark green leaves

and white flowers succeeded by globular red or black glossy fruit with a pleasant smell and taste, is a greenhouse shrub, hardy in south-west Britain. The common myrtle is the sole representative in Europe of a large genus (70 species) which has its headquarters in extra-tropical South America, whilst other members are found in Australia and New Zealand. The genus *Myrtus* also gives its name to a very large family, Myrtaceae (*q.v.*). The leaves of *M. Chekan* have been used in chronic bronchitis.

MYSIA, a district of north-west Asia Minor, bounded by Lydia and Phrygia on the south, by Bithynia on the north-east, and by the Propontis and Aegean Sea on the north and west. Its precise limits are difficult to assign, the Phrygian frontier being vague and fluctuating, while in the north-west the Troad was sometimes included in Mysia, sometimes not.

The most important cities were Pergamum (*q.v.*) in the valley of the Caicus and Cyzicus (*q.v.*) on the Propontis. But the whole sea-coast was studded with Greek towns, several of which were places of considerable importance; thus the northern portion included Parium, Lampsacus and Abydos, and the southern Assus, Adramyttium, and farther south, on the Elaitic Gulf, Elea, Myrina and Cyme.

Ancient writers agree in describing the Mysians as a distinct people, like the Lydians and Phrygians, though they never appear in history as an independent nation. That they were kindred with the Lydians and Carians, is attested by their common participation in the sacred rites at the great temple of Zeus at Labranda, as well as by the statement of the historian Xanthus of Lydia that their language was a mixture of Lydian and Phrygian. Strabo was of opinion that they came originally from Thrace (see BITHYNIA), and were a branch of the same people as the Mysians or Moesians (see MOESIA) who dwelt on the Danube. The Mysians appear in the list of the Trojan allies in Homer; the first historical fact we learn is their subjugation, together with all the surrounding nations, by Croesus of Lydia. After the fall of the Lydian monarchy they remained under the Persian empire until its overthrow by Alexander; they continued to form a part of the Syrian monarchy until the defeat of Antiochus the Great (190 B.C.), after which they were transferred by the Romans to the dominion of Eumenes of Pergamum. After the extinction of the Pergamian dynasty (130 B.C.) Mysia became a part of the Roman province of Asia.

See J. A. R. Munro in *Geogr. Journal* (1897, Hellespontica); W. von Diest, *Petermanns Mitth.* (Erganzungsheft 94, Gotha, 1889; Pergamene). *Cambridge Ancient History*, vol. iii. (with useful bibliography).

MYSLOWICE (Ger. *Myslowitz*), a town of Poland on the river Przemska. It is 120 m. S.E. of Breslau by rail and an important railway junction. Pop. (1919) 18,115. It became a town in 1857 and is in an industrial area with coal mines, flax spinning and brick making.

MYSORE, the capital of the state of Mysore, India, 10 m. S.W. of Seringapatam on the Mysore State railway. Pop. (1921), 83,951. The city, which is spread over a large area, has its nucleus at the foot of the Chamundi hill, in a valley formed by two parallel ridges running north and south. The fort stands in the south of the town, forming a quarter by itself; the ground-plan is quadrangular, each of the sides being about 450 yd. long. The palace of the maharaja within the fort contains the throne said to have been presented to Chikka Deva Raj by the emperor Aurangzeb. The houses of the European residents are for

MYRTLE (*MYRTUS COMMUNIS*), SHOWING FLOWERING BRANCH AND VERTICAL SECTION OF FLOWER

the most part east of the town. The residency or government house was built in 1805. The building afterwards used for the district offices was originally built by Colonel Wellesley (duke of Wellington) for his own occupation. The domed building for the public offices in Gordon park, the Maharajah and Maharani's training colleges, the Mary Holdsworth hospital, the fine new Palace offices and the law courts are conspicuous. A teaching and residential university was established in 1916, and the Mysore Bank in 1913. There is also a chamber of commerce. Mysore, though the dynastic capital of the state, was superseded by Seringapatam as the seat of the court from 1610 to 1799, and in 1831, on the British occupation, the seat of administration was removed to Bangalore.

MYSORE, a native state of southern India, almost surrounded by the Madras presidency, but in political relations with the governor-general. It is naturally divided into two regions of distinct character—the hill country called the Malnad, on the west, and the more open country known as the Maidan, comprising the greater part of the state, where the wide-spreading valleys and plains are covered with villages and populous towns. The drainage of the country, with a slight exception, finds its way into the Bay of Bengal, and is divisible into three great river systems—that of the Kistna on the north, the Cauvery on the south, and the Northern and Southern Penner and Palar on the east. Owing to either rocky or shallow beds none of the Mysore rivers is navigable. The main streams, especially the Cauvery and its tributaries, support an extensive system of irrigation by means of channels drawn from immense dams (*anicut*s), which retain the water at a high level and permit only the overflow to pass down stream. The streams are embanked to form reservoirs or tanks.

Mysore is a very prosperous state. Situated on a healthy plateau, it receives the benefit of both the south-west and north-east monsoons, which, in conjunction with its irrigation system, has brought it a large degree of immunity from famine. The silk industry and gold mining are very profitable, and two sandalwood-oil factories have recently been opened. Manganese, mica and steatite are worked. The famous Kolar gold-fields are worked by electric power, which is conveyed for a distance of 92 m. from the Cauvery falls. A long period of administration by British officers led to the introduction of a system based on British models, and the state has developed rapidly in recent years. Departments of industry and commerce and of agriculture have been organized, welfare work for the agricultural population undertaken, a Public Health institution started, and a university opened at Mysore. There is an agricultural college, and several experimental farms.

The total area of the state, including the civil and military station of Bangalore, is 29,469 sq.m., subdivided into 8 districts, namely: Bangalore, Kolar, Tumkur, Mysore, Hassan, Kadir, Shimoga and Chitaldrug. Pop. (1921), 862,628. The influenza epidemic of 1918 was very serious in the state. Kannda is spoken by the majority of the people, $\frac{1}{4}$ of whom are engaged in agriculture. The proportion of Hindus, who are 16 times as numerous as the Mohammedans, shows how ineffectual was the persecution of Hyder and Tippoo. Of the 71,000 Christians, 57,500 are Roman Catholics. The finances of the state have been successfully managed under native rule, assisted by large profits from railways and gold-mines. The revenue amounts to about £2,278,000, largely derived from land, and a subsidy and peshkash of £233,333 is paid to the British government. The state maintains a military force, which numbered 2,780 in 1925. A representative assembly has been in existence since 1881. In 1923 it was placed on a statutory basis, its powers extended, and the franchise widened. There is also a legislative council of 50 members, 30 non-official and 20 official.

History.—In the earliest historical times the north of Mysore was held by the Kadamba dynasty, whose capital, Banawasi, is mentioned by Ptolemy; they reigned during fourteen centuries, though later they became feudatories of the Chalukyas (*q.v.*). The Cheras were contemporary with the Kadambas, and governed the southern part of Mysore till they were subverted by the Cholas in the 8th century. Another ancient race, the Pallavas, held a small portion of the eastern side of Mysore, but

were overcome by the Chalukyas in the 7th century. These were overthrown in the 12th century by the Ballalas (Hoysalas), an enterprising and warlike race professing the Jain faith. They ruled over the greater part of Mysore, and portions of the modern districts of Coimbatore, Salem and Dharwar, with their capital at Dwarasamudra (the modern Halebid); but in 1310 the Ballala king was captured by Malik Kafur, the general of Ala-ud-din; and seventeen years later the town was entirely destroyed by another force sent by Mohammed Tughlak. After the subversion of the Ballala dynasty, a new and powerful Hindu sovereignty arose at Vijayanagar. In 1565 a confederation of the Mohammedan kingdoms defeated the Vijayanagar sovereign at the battle of Talikota. The most important of the petty local chiefs was the *wodeyar* of Mysore, who in 1610 seized the fort of Seringapatam, and so laid the foundation of the present state. His fourth successor, Chikka Deva Raja, during a reign of 34 years, made his kingdom one of the most powerful in southern India. In the middle of the 18th century the famous Mohammedan adventurer Hyder Ali (*q.v.*), usurped the throne. His dynasty, however, was as brief as it was brilliant, and ended with the defeat and death of his son Tippoo at Seringapatam in 1799. Krishnarajah Wodeyar, only five years old, was placed on the throne, and until he came of age in 1811 the state was under the administration of Purnaiya, the Brahman minister of Hyder and Tippoo. When Krishnarajah took over the management of his state he received an orderly and contented principality with a surplus of two crores of rupees. Within twenty years he had driven his subjects into rebellion and involved himself and his state in heavy debt. The British government therefore assumed the administration in 1831, and placed it in the hands of commissioners. In 1867 it was determined to secure the continuance of native rule in Mysore and on March 25, 1881, Chamarajendra, Krishnarajah's successor, having attained the age of 18 years, was publicly entrusted with the administration of the state.

He made over to the British a small tract at Bangalore, forming the "civil and military station," and received in return the island of Seringapatam. By the signing of the "instrument of transfer," the young maharajah, for himself and his successors, undertook to perform the conditions imposed upon him. The maharajah died at Calcutta on Dec. 28, 1894. His eldest son, the present ruler, Krishnarajah Wadiyar, born in 1884, succeeded him, and his widow, Maharani Vanivilas, was appointed regent, until in 1902 the maharajah was formally invested with full powers by the viceroy in person. In 1913 the "instrument of transfer" was replaced by a treaty, and in 1927 the government of India remitted in perpetuity 10½ lakhs of the annual subsidy.

See F. L. Rice, *Mysore* (2nd ed., Bangalore, 1897); *Mysore and Coorg Gazetteer* (Calcutta, 1908); the annual *Administration Report* (Bangalore).

MYSTERY. It is necessary to differentiate *mystery*, Gr. *μυστήριον*, from its homophone, properly written *mistry*, late Lat. *ministerium*, a trade or craft; hence *mystery plays* (see **DRAMA**), those performed by trade-gilds. We must also set aside the Hellenistic meaning, common in modern languages, of "secret," "puzzling occurrence."

Properly, then, a mystery is a Greek rite which is kept secret (*μύειν*, to shut the mouth or eyes) from all save the initiated (*οἱ μύσται, οἱ μυστημένους*). These are specially prepared to have the secret revealed to them, under the guidance of a hierophant (*ιεροφάντης*, "revealer of holy things"). According to Theon Smyrnaeus (*de util. math.*, p. 15, Hercher) there were four stages: (1) preliminary purification (*καθαρός*); (2) communication of mystic knowledge, *τελετῆς παράδοσις*, presumably including a sort of sermon of instruction or exhortation; (3) *ἐποπτεία*, or revelation of the holy things, the central point of the rite; (4) the crowning or garlanding of the mystic, who was thus, as it were, badged as a privileged person. We know that the central revelation was something done (*δρῶμενον*), not spoken, or not merely spoken; Lucian says (*de saltat.*, 15) that all mysteries included dancing. Hence it is usually, and reasonably, concluded that some sort of pageant or rudimentary sacred drama was shown.

We may now ask why the rites should be secret at all. A plausible but mistaken explanation has recently been revived by O. Kern (*Die Religion der Griechen*, i. 1926): the invading Hellenes oppressed, perhaps actually used religious persecution against, the earlier inhabitants of Greece, hence driving their cults into secrecy.

It might be urged in favour of this view that in Crete, according to Diodorus Siculus (v. 77, 3), rites similar to the Greek mysteries lay open to all and had nothing "mysterious" about them, and also that the *telesterion* or hall of initiation at Eleusis originates in Minoan-Mycenaean constructions, and Eleusis itself has a name probably pre-Greek (*cp.* A. W. Persson in *Archiv f. Religionswissenschaft*, xxi., p. 291 ff.; M. P. Nilsson, *Minoan-Mycenaean Religion*, 1927, p. 402, ff.); furthermore, that several survivals of things pre-Hellenic have been more or less certainly traced in the ritual of the mysteries, Eleusinian and other. But these considerations can hardly avail against the facts that the mystic deities include many undoubtedly Greek, as *Demeter*, *Kore*, *Ge*, *Aglauros*, the *Charites*, *Hecate*, and others; that the ritual is in the hands of noble and distinguished families, not of slaves or other remnants of a conquered population; and that a good magico-religious reason for secrecy can be given. The deities of these cults are one and all chthonian; these, however benevolent, are in their nature dangerous to approach; therefore, to avoid all possibility of disturbance at a critical time, it is but prudent to shroud the whole performance in secrecy, and keep the impure and unprepared at a safe distance.

For the student of Hellenism, the Eleusinian and Orphic ceremonies are of paramount importance; the Samothracian, which vied with these in attractiveness for the later Hellenic world, were not Hellenic in origin; nor wholly hellenized in character, and cannot be considered in an article of this compass.

As regards the Eleusinia, we are in a better position for the investigation of them than our predecessors were; for the modern methods of comparative religion and anthropology have at least taught us to ask the right questions and to apply relevant hypotheses; archaeology, the study of vases, excavations on the site, yielding an ever-increasing hoard of inscriptions, have taught us much concerning the external organization of the mysteries, and have shown us the beautiful figures of the deities as they appeared to the eye or to the mental vision of the initiated.

In seeking to guess what the secret of the mysteries was, we must first rid ourselves of the notion that it was any esoteric philosophy, or elaborate theology kept hidden from the world at large. Negatively, we have no jot of evidence that the initiates were more intelligent than the rest of Greece, or that their belief or practice differed from those of their fellow-countrymen to any marked degree, although there need be no doubt that a certain amount of verbal instruction was given by the hierophant (see below). Positively, we have the repeated insistence, from the Homeric hymn down (*hymn. Homer*, ii., 480) that the initiates saw something which greatly comforted their souls, not that they learned anything of great importance. What they saw was doubtless the sacred *dromenon*. We can realize what effect this might have on excited and believing minds, if we consider the importance, for a pious Catholic, of such impressive ceremonies as the elevation of the Host at mass.¹

Our evidence is of two kinds. Firstly, a number of works of art show us scenes probably or certainly taken from the ritual of the Eleusinian or other mysteries. But here we may be certain that the artists, even if they themselves had no scruples, would not risk violating the deepest religious sentiments of thousands of their fellow-countrymen. Secondly, we have literary evidence. But this, if pagan, is restrained by the same reasons as the artists' from saying too much; if Christian, the writers seldom, if ever, can be shown to have been initiates themselves; some indeed cannot have been, for they were never pagans. Their

¹This is well and sympathetically discussed by O. Kern, *Die griechischen Mysterien der klassischen Zeit* [1927], especially p. 23 ff. Aristotle [*frag.* 45, Rose] declares that the *mystai* learned nothing, but underwent "an experience and an influence" [*παθεῖν καὶ διατεθῆναι*]; an important testimony.

statements are generally uncritical and do not clearly differentiate between the Eleusinian mysteries and others, such as the Orphic, Sabazian, and those of Cybele and Attis.

The questions that the critical analysis of all the evidence may hope to solve are mainly these: (a) What do we know or what can we infer concerning the personality of the deities to whom the Eleusinian mysteries were originally consecrated, and were new figures admitted at a later period? (b) When was the mystery taken over by Athens and opened to all Hellas, and what was the state-organization provided? (c) What was the inner significance, essential content or purport of the Eleusinia, and what was the source of their great influence on Hellas? (d) Can we attribute any ethical value to them, and did they strongly impress the popular belief in immortality? Limits of space allow us only to adumbrate the results that research on the lines of these questions has hitherto yielded.

The paramount divine personalities of the mystery were, in the earliest period of which we have literary record, the mother and the daughter, Demeter and Kore, the latter being never styled Persephone in the official language of Eleusis; while the third figure, the god of the lower world known by the euphemistic names of Pluto (Plouton) and at one time Eubouleus, the ravisher and the husband, is an accessory personage, comparatively in the background. This is the conclusion naturally drawn from the Homeric hymn to Demeter, a composition of great ritualistic value, probably of the 7th century B.C., which describes the abduction of the daughter, the sorrow and search of the mother, her sitting by the sacred well, the drinking of the *κυκεών* or sacred cup, and the legend of the pomegranate. An ancient hymn of Pamphos, from which Pausanias freely quotes and which he regards as genuine¹, appears to have told much the same story in much the same way. As far as we can say, then, the mother and daughter were there in possession at the very beginning. The other pair of divinities known as *ὁ θεός, ἡ θεά* that appear in a 5th century inscription and on two dedicatory reliefs found at Eleusis, have been supposed to descend from an aboriginal period of Eleusinian religion when deities were nameless². But for various reasons the contrary view is more probable, that *ὁ θεός* and *ἡ θεά* are later cult-titles of the married pair Pluto-Cora (Plouton-Kore), the personal names being omitted from that feeling of reverential shyness which was specially timid in regard to the sacred names of the deities of the underworld. And it is a fairly familiar phenomenon in Greek religion that two separate titles of the same divinity engender two distinct cults.

The question as to the part played by Dionysus in the Eleusinia is important. Some scholars, like M. Foucart, have supposed that he belonged from the beginning to the inner circle of the mystery; others that he forced his way in at a somewhat later period owing to the great influence of the Orphic sects who captured the stronghold of Attic religion and engrafted the Orphic-Sabazian *ἱερός λόγος*, the story of the incestuous union of Dionysus-Sabazius with Demeter-Kore, and of the death and rending of Zagreus, upon the primitive Eleusinian faith. A saner and more careful criticism rejects this view. There is no genuine trace discovered as yet in the inner circle of the mysteries of any characteristically Orphic doctrine; the names of Zagreus and Phanes are nowhere heard, the legend of Zagreus and the death of Dionysus are not known to have been mentioned there. Nor is there any print within or in the precincts of the *τελεστήριον*, the hall of the *Μύσται*, of the footsteps of the Phrygian deities, Cybele, Attis, Sabazius.

The exact relation of Dionysus to the mysteries involves the question as to the divine personage called Iacchus; who and what was Iacchus? Strabo (p. 468), who is a poor authority on such matters, describes him as "the daemon of Demeter, the founder of the leader of the mysteries." More important is it to note that "Iacchus" is unknown to the author of the Homeric hymn, and that the first literary notice of him occurs in the well-known

passage of Herodotus (viii. 65), who describes the procession of the mystae as moving along the sacred way from Athens to Eleusis and as raising the cry *Ἰακχε*. We find Iacchus the theme of a glowing invocation in an Aristophanic Ode (*Frogs*, 324-398), and described as a beautiful "young god"; but he is first explicitly identified with Dionysus in the beautiful ode of Sophocles' *Antigone* (1119); and that this was in accord with the popular ritualistic lore is proved by the statement of the scholiast on Aristophanes (*Frogs*, 482) that the people at the Lenaea, the winter-festival of Dionysus, responded to the command of "Invoke the god!" with the invocation "Hail, Iacchus, son of Semele, thou giver of wealth!" We are sure, then, that in the high tide of the Attic religious history Iacchus was the youthful Dionysus, a name of the great god peculiar to Attic cult, and this is all that here concerns us to know.

We thus see that Iacchus was an Athenian, not an Eleusinian, god; his abiding-place was Athens, and he merely visited Eleusis for the mysteries. We may indeed conjecture that his votaries read Dionysiac interpretations into Eleusinian *dromena*. But all this is conjecture. The interpretation of what was shown would naturally change somewhat with the changing sentiment of the ages; but Demeter and Kore, *τῷ θεῷ*, and no one else, are the paramount figures at Eleusis from the "Homeric" hymn to Alaric's invasion. Triptolemus the apostle of corn-culture, Eubouleus—originally a euphemistic name of the god of the under-world, "the giver of good counsel," conveying a hint of his oracular functions—these are accessory figures of Eleusinian cult and mythology that may have played some part in the great mystic drama that was enacted in the hall.

As to the history of the Eleusinian mysteries¹, the legends concerning the initiation of Heracles and the Dioscuri imply that originally they were closed to strangers, which, as they probably were in origin local rites in honour of local deities, is exactly what we should expect. But the "Homeric" hymn implies that they are open to all; with this we may connect the sagas of the conquest of Eleusis by Athens (see EUMOLPUS) and the early unification of Attica under Theseus (see CONSTITUTION OF ATHENS). By what steps the mysteries grew in importance and fame we do not know, but certainly Peisistratus paid attention to them, while Pericles found them highly important and made them more so. Decrees of his time² proclaim a holy truce for pilgrims to the festival and invite the subject-allies of Athens to send first-fruits of corn, a part of his imperial policy. The *μυστικὸς σῆκος* at Eleusis is of his date.

At least from the 5th century onwards, Athens was in charge of the organization and external control of the mysteries, the management being in the hands of the archon basileus and a committee of four *epimeletai* (overseers) and a *paredros* (assessor). The State, as elsewhere in Greece, controlled the Church. But the priesthood was Eleusinian. Two ancient clans, the *Eumolpidae* (see EUMOLPUS) and the *Kerukes* (see HERALD) performed the whole ceremony between them; it appears that in the 4th century the *Kerukes* died out and the *Lukomidae* of Phlye took their place, perhaps bringing with them a tendency to Orphism. From the Eumolpidae was chosen the hierophant, who was so holy that his personal name was no longer used when once he was appointed, and he alone might enter the innermost shrine,—or perhaps, for the details are obscure, he and a priestess. Demeter and Kore had also each a *hierophantis* or female hierophant; considering that the Thesmophoria (*q.v.*) was entirely in the hands of women, it is not surprising that they took part in the mysteries also. The *Kerukes*, afterwards the *Lukomidae*, chose the *δαδούχος* or torch-bearer, who ranked next after the hierophant, from their number.

Turning now to the celebration itself, we can only sketch the more salient features here. On the 13th of Boedromion, the Attic month corresponding roughly to our September, the Ephebi (*q.v.*) marched out to Eleusis, and returned to Athens the next

¹To be distinguished from the Eleusinia, an important festival, but not connected with the mysteries, see *Revue des études grecques*, xxii., p. 462.

²Dittenberger, *Sylloge*, 3rd. ed. 21 (=I.G. i. 1); 83, 30 ff.

day, bringing with them the "holy things" (*ιερά*) to the "Eleusinion" in the city; these *ιερά* probably included small images of the goddesses. The 16th was the day of the *ἀγυρμός*, the gathering of the catechumens, when they met to hear the address of the hierophant, called the *πρόρρησις*. This was no sermon, but a proclamation bidding those who were disqualified or for some reason unworthy of initiation to depart. The legally qualified were all Hellenes and subsequently all Romans above a certain—very youthful—limit of age, women, and as it appears even slaves; barbarians, and those uncleansed of some notorious guilt, such as homicide, were disqualified. We are sure that there was no dogmatic test, nor would time allow of any searching moral scrutiny, and only the Samothracian rites, in this respect unique in the world of classical religion, possessed a system of confessional. The hierophant appealed to the conscience of the multitude; but we are not altogether sure of the terms of his proclamation, which can only be approximately restored from late pagan and early Christian writers. We know that he demanded of each candidate that he should be "of intelligible speech (*i.e.*, Hellenic) and pure of hand"; and he catechized him as to his condition of ritualistic purity—the food he had eaten or abstained from. It appears also from Libanius that in the later period at least he solemnly proclaimed that the catechumen should be "pure of soul" (*Or. Corinth*, iv. 356), and this spiritual conception of holiness had arisen already in the earlier periods of Greek religious thought. On the other hand we must bear in mind the criticism that Diogenes is said to have passed upon the Eleusinia, that many bad characters were admitted to communion, thereby securing a promise of higher happiness than an uninitiated Epameinondas could aspire to.

An essential preliminary was purification and lustration, and after the assembly the "mystae" went to the sea-shore (*ἄλαδε μύσται*) and purified themselves with sea-water, and probably with sprinkling of pigs' blood, a common cathartic medium. After their return from the sea, a sacrifice of some kind was offered as an essential condition of *μύσις*, but whether as a sacrament or gift-offering to the goddesses it is impossible to determine. On the 19th of Boedromion the great procession started along the sacred way bearing the "fair young god" Iacchus; and as they visited many shrines by the way the march must have continued long after sunset, so that the 20th is sometimes spoken of as the day of the exodus of Iacchus. On the way each wore a saffron band as an amulet; and the ceremonious reviling to which the *μύσται* were subjected as they crossed the bridge of the Cephissus answered the same purpose of averting the evil eye. Upon the arrival at Eleusis, on the same night or on the following, they celebrated a midnight revel under the stars with Iacchus, which Aristophanes glowingly describes.

The question of supreme interest now arises: What was the mystic ceremony in the hall; what was said and what was done? We can distinguish two grades in the celebration; the greater was the *τέλεα* and *ἐποπτικά*, the full and satisfying celebration, to which only those were admitted who had passed the lesser stage at least a year before. As regards the actual ritual in the hall of the mystae, much is still uncertain. That there was some kind of holy pageant or play, the accusations against Aeschylus and Alcibiades would suffice to prove, and Porphyry speaks of the hierophant and the *δαδούχος* acting divine parts. What the subject of this drama was may be gathered partly from the words of Clement—"Deo (Demeter) and Kore became the personages of a mystic drama, and Eleusis with its *δαδούχος* celebrates the wandering, the abduction and the sorrow" (*Protrept.*, p. 12, Potter), supported by Apuleius (*Met.* vi., 2). We may believe then that the great myth of the mother's sorrow, the loss and the partial recovery of her beloved was part of the Eleusinian passion-play. Did it also include a *λεπὸς γάμος*? We should naturally expect that the sacred story acted in the mystic pageant would close with the scene of reconciliation, such as a holy marriage of the god and the goddess. But the evidence that this was so is mainly indirect, apart from a doubtful passage in Asterius, a writer of questionable authority in the 4th century A.D. (*Econom. marty.* p. 194, Combe). At any rate, if a holy

marriage formed part of the passion-play, it may well have been acted with solemnity and delicacy. We have no reason to believe that even to a modern taste any part of the ritual would appear coarse or obscene; even Clement, who brings a vague charge of obscenity against all mysteries in general, does not try to substantiate it in regard to the Eleusinia, and we hear from another Christian writer of the scrupulous purity of the hierophant.

It would be interesting to know if the birth of a holy child, a babe Iacchus, for example, was a motive of the mystic drama. The question seems at first sight to be decided by a definite statement of Hippolytus (*Philosoph.* 5. 8), that at a certain moment in the mysteries the hierophant cried aloud: "The lady-goddess Brimo has borne Brimos the holy child." But a careful consideration of the context almost destroys the value of his authority. For he does not pretend to be a first-hand witness, but admits that he is drawing from Gnostic sources, and he goes on at once to speak of Attis and his self-mutilation. The formula may then refer to the Sabazian-Phrygian mystery, which the Gnostics with their usual spirit of religious syncretism would have no scruple in identifying with the Eleusinian. And the archaeological evidence that has been supposed to support the statement of Hippolytus is deceptive.

The simple structure of the building and the absence of any reference, in the many inscriptions, to expenses for scenery or the like forbid us to suppose that there was any elaborate staging. The pageant-play produced its effect by means of gorgeous raiment, torches and stately figures.

But the mystic action included more than the pageant-play. The hierophant revealed certain holy objects to the eyes of the assembly. There is reason to suppose that these included certain primitive idols of the goddesses of immemorial sanctity; and, if we accept a statement of Hippolytus (*loc. cit.*) we must believe that the *εποπταί* were also shown "that great and marvellous mystery of perfect revelation, a cut corn-stalk." The value of this definite assertion, which appears to be an explicit revelation of the secret, would be very great, if we could trust it; but unfortunately it occurs in the same suspicious context as the Brimo-Brimos formula, and we again suspect the same uncritical confusion of Eleusinian with Phrygian ritual, for we know that Attis himself was identified in his mysteries with the "reaped corn," the *στάχυς ἀμητος*, almost the very phrase used by Hippolytus. Only, it is in the highest degree probable, whether Hippolytus knew anything or not, that a corn-token was shown among the sacred things of a mystery which possessed an original agrarian significance and was intended partly to consecrate and to foster the agricultural life. But to say this is by no means the same as to admit the view of Lenormant¹ and Dr. Jevons² that the Eleusinians worshipped the actual corn, or revered it as a clan-totem. For of direct corn-worship or of totemism there is no trace either at Eleusis or elsewhere in Greece.

Among the *δρώμενα* or "things done" may we also include a solemn sacrament, the celebration of a holy communion, in which the votary was united to the divinity by partaking of some holy food or drink? We owe to Clement of Alexandria (*Protrept.* p. 18, Potter) an exact transcription of the pass-word of the Eleusinian mystae; it ran as follows (if we accept Lobbeck's emendation of *ἐγγενεσάμενος* for *ἐργασάμενος*) "I have fasted, I have drunk the barley-drink, I have taken (the things) from the sacred chest, having tasted thereof I have placed them into the basket and again from the basket into the chest." We gather from this that some kind of sacrament was at least a preliminary condition of initiation; the mystae drank of the same cup as the goddess drank in her sorrow, partly—as we say—"in memory of her," partly to unite themselves more closely with her. We know also from an inscription that the priest of the Samothracian mysteries broke sacred bread and poured out drink for the mystae (*Arch. epigr. Mitth.*, 1882, p. 8, No. 14). But neither in these nor in the Eleusinian is there any trace of the more mystic sacramental conception, any indication that the votaries believed themselves to be partaking of the actual body of their

¹Daremberg et Saglio. *Dictionnaire*, i., p. 1066.

²Introduction to the Study of Religion.

divinity¹, for there is no evidence that Demeter was identified with the corn, still less with the barley-meal of which the *κυκεὼν* was compounded. Nor is it likely that the sacrament was the pivot of the whole mystery or was part of the essential act of the *μῆσις* itself. In the first place we have an almost certain representation of the Eleusinian sacrament on an archaic vase in Naples², probably of Attic *provenance*, and the artistic reproduction of a holy act would have been impious and dangerous, if this had belonged to the inner circle of the mystery. Again, there is no mention of sacrament or sacrifice among the five essential parts of *μῆσις* given by Theo Smyrnaeus, nor in the imaginary narrative of the late rhetorician Sopatros (*Rhet. Graec.* viii., 121) who supposes the strange case of a man being initiated by the goddesses in a dream: they admit him to their full communion merely by telling him something and showing him something.

Besides the *δρώμενα*, then, there were also certain things said in the hall, or in the earlier stages of initiation, which we would gladly discover. Part of these were mystic formulae, one of which has been discussed already, the pass-word of the votaries. We gather also from Proclus and Hippolytus (*in Tim.* 293^c; *Ref. Omn. Haer.* 5, 7, p. 146) that in the Eleusinian rites they gazed up to heaven and cried aloud "rain"—*ἔε*—and gazed down upon the earth and cried "conceive"—*κτε*. This ritual charm—we cannot call it prayer—descends from the old agrarian magic which underlay the primitive mystery. What else the votaries may have uttered, whether by way of thanksgiving or solemn litany, we do not know³. But there was also a certain *ἑρπὸς λόγος* some exposition accompanying the unfolding of the mysteries; for it was part of the prestige of the hierophant that he was chief spokesman, "who poured forth winning utterance and whose voice the catechumen ardently desired to hear" (*Anth. Pal.*, app. 246); and Galen speaks of the rapt attention paid by the initiated "to the things done and said in the Eleusinian and Samothracian mysteries" (*De usu part.* 7. 14). But we have no trustworthy evidence as to the real content of the *λόγος* of the hierophant. We need not believe that the whole of his discourse was taken up with corn-symbolism, as Varro seems to imply (*Aug. de civit. Dei.* 20), or that he taught natural philosophy rather than theology, or again, the special doctrine of Euhemerus, as two passages in Cicero (*De natur. deor.* i. 42; *Tusc.* i. 13) might prompt us to suppose. His chief theme was probably an exposition of the meaning and value of the *ἑρπὰ* as in an Australian initiation rite it is the privilege of the elders to explain the nature of the "churinga" to the youths. And his discourse on these may have been coloured to some extent by the theories current in the philosophic speculation of the day. But though in the time of Julian he appears to have been a philosopher of Neo-platonic tendencies, we ought not to suppose that the hierophant as a rule would be able or inclined to rise above the anthropomorphic religion of the times. Whatever symbolism attached to the *ἑρπὰ*, the sacred objects shown, was probably simple and natural; for instance, in the Eleusinian, as in Egyptian eschatology, the token of the growing corn may have served as an emblem—though not a proof—of man's resurrection. The doctrine of the continuance of the soul after death was already accepted by the popular belief, and the hierophant had no need to preach it as a dogma; the votaries came to Eleusis to ensure themselves a happy immortality. And in our earliest record, the Homeric hymn, we find that the mysteries already hold out this higher promise. How, we may ask, were the votaries assured? The Egyptianizing theory of Foucart, that they were given directions and spells to take them past the terrors of the underworld, after the manner of the

Book of the Dead, is wholly improbable. The terror of hell is not normal Greek, although something of the kind existed in Orphism; nor have we any evidence that spells of any kind were taught or that the *λόγος* was regarded as particularly important. If we could be sure that the Minoans had a developed eschatology (see Evans in *Journ. Hell. Stud.*, xiv. p. 43 ff., but cf. Nilsson, *Minoan-Myc. Rel.*, p. 549 ff.), we might suppose some of it to survive; but the matter is very doubtful.

The assurance of the hope of the Eleusinian votary was obtained by the feeling of friendship and mystic sympathy, established by mystic contact, with the mother and the daughter, the powers of life after death. Those who won their friendship by initiation in this life would by the simple logic of faith regard themselves as certain to win blessing at their hands in the next.

That the mysteries preached a higher morality than that of the current standard is not proved. That they exercised a direct and elevating influence on the individual character is nowhere explicitly maintained, as Diodorus (v. 49) maintains concerning the Samothracian. But on general grounds it is reasonable to believe that such powerful religious experience as they afforded would produce moral fruit in many minds. The genial Aristophanes (*Frogs*, 455) intimates as much, and Andocides (*De myster.* p. 36, § 31; p. 44, § 125) assumes that those who had been initiated would take a juster and sterner view of moral innocence and guilt.

Besides the greater mysteries at Eleusis, we hear of the lesser mysteries of Agrae on the banks of the Ilissus. Established, perhaps, originally by Athens herself at a time when Eleusis was independent and closed her rites to strangers, they became wholly subordinated to the greater, and were put under the same management and served merely as a necessary preliminary to the higher initiation into them. Sacrifice was offered to the same great goddesses at both; but we have the authority of Duris (*Athenae*, 253d), the Samian historian, and the evidence of an Attic painting, called the *pinax* of Nannion¹, that the predominant goddess in the mysteries at Agrae was Kore. And this agrees with the time of their celebration, in the middle of Anthesterion, when Kore was supposed to return in the young corn. Stephanus (s.v. *Ἀγρὰ*), drawing from an unknown source, declares that the Dionysiac story was the theme of their mystic drama; an isolated statement with nothing to confirm or interpret it.

The influence of Eleusis in early times must have been great, for we find offshoots of its cult, whether mystic or not, in other parts of Greece. In Boeotia, Laconia, Arcadia, Crete and Thera, Demeter was called Eleusinia, meaning in all probability "goddess of Eleusis." The initiation rites of Demeter at Celae near Phlius, at Lerna in Argolis, and at Naples, were organized after the pattern of the Eleusinian. But of these and the other Demeter mysteries in the Greek world, there is little to record that is certain and at the same time of primary importance for the history of religion. The Arcadian city of Pheneus possessed a mystery that boasted an Eleusinian character and origin, yet in the record of it there is no mention of Kore, and we may suspect that, like other Demeter-worships in the Peloponnese, it belonged to a period when the goddess was revered as a single personality and Kore had not yet emanated from her. We know much more of the details of the great Andanian mysteries in Messenia, owing to the discovery of the important and much-discussed Andanian inscription of 91 B.C.². But what we know are facts of secondary importance only. We gather from Pausanias (4. 33. 4; cf. 4. I. 5. and 4. 26. 8; 4. 27. 6) that the rites, which he regards as second in solemnity and prestige to the Eleusinian alone, were consecrated to the *Μεγάλαι θεαί* (the great goddesses) and that Kore enjoyed the mystic title of Hagnē, "the holy one." The inscription has been supposed to correct and to refute Pausanias, but it does not really controvert his statements, which are attested by other evidence; it proves only that other divinities came at

¹This is Dr. Jevons's supposition—*op. cit.*—on which he bases an important theory of the whole Eleusinian mysteries and their intrinsic attraction.

²(Farnell, *Cults*, vol. iii. pl. xv.b).

³The other formula which the scholiast on Plato (*Gorg.* 407 c.) assigns to the Eleusinian rite: "I have eaten from the timbrel, I have drunk from the cymbal, I have carried the sacred vessel, I have crept under the bridal-chamber," belongs, not to Eleusis, but, as Clement and Firmicus Maternus themselves attest, to Phrygia and to Attis.

¹Farnell, *Cults of the Greek States*, vol. iii. p. 242, Pl. xvi.

²See Sauppe, *Mysterieninschrift von Andania*; cf. Foucart's commentary in *Le Bas, Voyage archéol.* 2, No. 326a; H. Collitz, *Dialekt-inschriften*, 4689.

a later time to have a share in the mysteries, such as the *Μεγάλοι θεοί* who were probably the Cabeiri (*q.v.*). It is clear that the Andanian mysteries included a sacred drama, in which women personated the goddesses. The priestesses were married women, and were required to take an oath that they had lived "in relation to their husbands a just and holy life." We hear also of grades of initiation, purification-ceremonies, but of no sacrament or eschatologic promise; yet it is probable that these mysteries, like the Eleusinian, maintained and secured the hope of future happiness.

The Eleusinian faith is not wholly unattested by the grave-inscriptions of Hellas, though it speaks but rarely on these. The most interesting example is the epitaph of a hierophant who proclaims that he has found that "death was not an evil, but a blessing¹."

Of equal importance for the private religion of Greece were the Orphic mystic societies, bearing a Thracian-Phrygian tradition into Greece, and associated originally with the name of Dionysus, and afterwards with Sabazius also and the later cult-ideas of Phrygia². The full account of the Dionysiac mysteries would demand a critical study of the Dionysiac religion as a whole, as well as of the private sects that sprang up under its shadow. It is only possible here to indicate the salient characteristics of those which are of primary value for the history of religion.

Originally a great nature-god of the Thracian-Phrygian stock, powerful over all vegetation and especially revealing his power in the vine, Dionysus was forcing his way into Greece at least as early as the Homeric period, and by the 6th century was received into the public cults of most of the Greek communities. We can gather with some certainty or probability his aboriginal characteristics and the form of his worship. Being a god of the life of the earth, he was also a nether divinity, the lord of the world of souls, with whom the dead votary entered into privileged communion; his rites were mystic, and nightly celebrations were frequent, marked by wild ecstasy and orgiastic self-abandonment, in which the votary became at one with the divinity and temporarily possessed his powers; women played a prominent part in the ritual; a savage form of sacramental communion was in vogue, and the animal victim of whose flesh and blood the votaries partook was at times regarded as the incarnation of the divinity, so that the god himself might be supposed to die and to rise again; finally we may regard certain cathartic ideas as part of the primeval tradition of this religion. Admitted among the soberer cults of the Greek communities, it lost most of its wildness and savagery, while still retaining a more emotional ecstatic character than the rest. But this cooling process was arrested by a new wave of Dionysiac fervour that spread over Greece from the 7th century onwards, bringing with it the name of Orpheus, and engendering at some later date the Orphic brotherhoods (*thiasoi*). This religious movement may have started like the earlier one from the lands north of Greece; but Crete and even Egypt are supposed to have contributed much to the Orphic doctrine and ritual. Plato's contemptuous mention (*Rep.* 364A) of wandering Orphic initiators brings to our notice a phenomenon unknown elsewhere in Greek religion; the missionary spirit, the impulse to preach to all who would hear, which foreshadows the breaking down of the gentile religious barriers of the ancient world. And it is probable that some kind of "Orphic" propagandism, whether through books or itinerant mystery-priests, or both, had been in vogue some time before Plato. Orphism was known to Pindar (*Olym.* ii. and frags. 129-133 v. Christ) and Euripides, see *Hipp.* 952-4 and, yet more important, frag. 472 (*Nauck*) which attests the antiquity of these mystic Dionysiac associations in Crete. The initiated votary proclaims himself as sanctified to Zeus of Ida, to Zagreus and to the mountain-goddess Rhea-Cybele; he has fulfilled "the solemn rite of the banquet of raw flesh," and henceforth he "robes himself in pure

white and avoids the taint of childbirth and funerals and abstains from meat." And—what is most significant—he calls himself by the very name of his god—he is himself Βάκχος. In spirit and in most of its details the passage accords well with the *Bacchae* of Euripides, which reflects not so much the public worship of Greece, but rather the mystic Dionysiac brotherhoods. Throughout this inspired drama the votary rejoices to be one with his divinity and to call himself by his name, and this mystic union is brought about partly, though Euripides may not have known it, through "the meal of raw flesh" or the drinking of the blood of the goat or the kid or the bull. The sacramental intention of this is confirmed by abundant proof; even in the state-cult of Tenedos they dressed up a bull-calf as Dionysus and reverentially sacrificed it (*Ael. Nat. an.* 12. 34); those who partook of the flesh were partaking of what was temporarily the body of their god. The Christian fathers at once express their abhorrence of this savage *ὁμοφαγία* and reveal its true significance (Arnob. *Adv. nat.* 5. 119); and Firmicus Maternus (*De error.*, p. 84) attests that the Cretans of his own day celebrated a funeral festival in honour of Dionysus in which they enacted the life and the death of the god in a passion-play and "rent a living bull with their teeth."

But the most speaking record of the aspirations and ideas of the Orphic mystic is preserved in the famous gold tablets found in tombs near Sybaris, one near Rome, and one in Crete. These have been frequently published and discussed; and here it is only possible to allude to the salient features that concern the general history of religion. They contain fragments of a sacred hymn that must have been in vogue at least as early as the 3rd century B.C., and which was inscribed in order to be buried with the defunct, as an amulet that might protect him from the dangers of his journey through the under-world and open to him the gates of Paradise. The verses have the power of an incantation. The initiated soul proclaims its divine descent: "I am the son of Earth and Heaven." "I am perishing with thirst, give me to drink of the waters of memory." "I come from the pure": "I have paid the penalty of unrighteousness": "I have flown out of the weary, sorrowful circle of life." His reward is assured him: "O blessed and happy one, thou hast put off thy mortality and shalt become divine." The strange formula *ἐριφος ἐς γάλ' ἔπειτον* "I a kid fell into the milk," has been interpreted by Dieterich (*Eine Mithras-Liturgie*, p. 174) with great probability as alluding to a conception of Dionysus himself as *ἐριφος*, the divine kid, and to a ritual of milk-baptism in which the initiated was born again¹.

We discern, then, in these mystic brotherhoods, the germs of a high religion and the prevalence of conceptions that have played a great part in the religious history of Europe. And as late as the days of Plutarch they retained their power of consoling the afflicted (*Consol. ad. uxor.*, c. 10).

The Oriental mysteries, associated with Attis, Cybele, Isis and Sabazius, which invaded later Greece and early imperial Rome, were originally akin to these and contained many concepts in common with them. But their orgiastic ecstasy was more violent, and the psychical aberrations to which the votaries were prone through their passionate desire for divine communion were more dangerous. Emasculation was practised by the devotees of Attis, whatever the reason may have been², and the high priest himself bore the god's name. Or communion with the deity might be attained by the priest through the bath of blood in the taurobolium (*q.v.*), or by the gashing of the arm over the altar. A more questionable method which lent itself to obvious abuses, or at least to the imputation of indecency, was the simulation of a sacred marriage, in which the catechumen was corporeally united with the great goddess in her bridal chamber (Dieterich, *op. cit.* pp. 121-134). Prominent also in these Phrygian mysteries were the conception of rebirth and the belief, vividly impressed by solemn pageant and religious drama, in the death and resurrec-

¹*Eph. arch.* (1883) p. 81.

²The best account of the origin and development of the Dionysiac religion is in Rohde's *Psyche*, vol. i.; for Orphic ritual and doctrine see Roscher's *Lexikon*, art. *Orpheus*; J. E. Harrison, *Prolegomena to the Study of Greek Religion*, pp. 455-659, with critical appendix by G. Murray on the Orphic tablets; and cf. *ORPHEUS*.

tion of the beloved Attis. The Hilaria in which these were represented fell about the time of our Easter; and Firmicus Maternus reluctantly confesses its resemblance to the Christian celebration (Farnell, *Cults*, iii., 299).

The Eleusinian mysteries are far more characteristic of the older Hellenic mind. These later rites breathe an Oriental spirit, and though their forms appear strange and distorted they have more in common with the subsequent religious phenomena of Christendom. And the Orphic doctrine may have even contributed something to the later European ideals of private and personal morality¹.

BIBLIOGRAPHY.—C. A. Lobeck, *Aglaophamus* (1829) is still very useful for material. General discussion of the subject in M. P. Foucart, *Les grands mystères d'Eleusis* (1900); Goblet d'Alviella, *Eleusinia* (1903); L. R. Farnell, *Cults of the Greek States*, vol. iii. (1906), with collection of relevant passages. MYSTERY STORIES resolve themselves into many types or classes, of which the principal are riddle stories, ghost stories and detective stories. The third of these classes deserves to be classed as a separate branch of fiction from the very nature of its construction. By his terms of reference, the author is obliged to get the main action of the book already over in the first few chapters. This action is (apparently at least) a crime; and the interest of the book lies in determining the circumstances, the methods and the motives of it. The reader is invited to watch the investigation, and to match his wits against the author by attempting to unravel the mystery *pari passu* with the detective hero. Numerous modern novels of adventure wear the air of detective stories, and are often erroneously classed as such: e.g., those of John Buchan and of "Sapper." But the formula of the detective story demands more than mystification; it demands an initial *fait accompli*, the unravelling of which is the principal interest of the book.

It is difficult to suppose that the mystery story has any literary antecedents earlier than the 19th century. The *Oedipus Tyrannus* of Sophocles would be a detective story if the reader did not know the plot beforehand, but this condition was not realized when the play was produced. The art seems to have developed almost simultaneously in France and in the United States of America, suggested perhaps by that modern organization of the police system which the Industrial Revolution brought with it and by the publication of the *Mémoires* of the celebrated criminal-detective Vidocq. Émile Gaboriau was certainly the first writer who introduced the European public to the whole notion of "clues," "deduction," and the detective method generally. In the United States the happy genius of Edgar Allan Poe (1809-49) gave birth to the detective story as it did to the short story itself. Poe achieved what is probably a unique distinction, that of having solved a real police mystery under the guise of fiction and having been proved right by subsequent confessions. "The Mystery of Marie Roget" gives a true account of what happened in the case of Mary Cecilia Rogers (1842), though the scene has been transferred from New York to Paris. Yet the development of the art belongs to England. Few detective stories since produced in the United States have had any considerable public in Europe; and although in our own day Gaston Leroux has revived the tradition of Gaboriau in *The Mystery of the Yellow Room*, he suffers, like Gaboriau himself, from grave limitations of constructive power.

One great detective achievement stands out in the Middle Victorian period, *The Moonstone*, by Wilkie Collins (1824-89). His prolixity is intolerable to the modern reader, but the ingenuity of his work is beyond cavil. Probably, however, more impetus was given to this movement in fiction by a story which is not really a detective story at all—Dickens' *Mystery of Edwin Drood*. Since the author died without completing the book, or even committing the true solution to writing, the ingenuity of critics was naturally challenged; four attempted solutions appeared between 1870

and 1880, and there has been, since then, a whole literature on the subject, to which Andrew Lang contributed (see "Edwin Charles," *Keys to the Drood Mystery*, 1908). It was almost before the scent of that trail had grown cold that Sir Arthur Conan Doyle standardized the art and left his permanent impress upon it by the appearance of the Sherlock Holmes stories.

These belong to the world of 1890-1900; *The Hound of the Baskervilles* is the only truly successful revival that Sir Arthur has achieved during the present century, although he has been obliged repeatedly to bring his hero back to his triumphs in order to satisfy the popular demand. The principal importance of his contribution to detective fiction lies in his concentration of interest upon the personality of the detective. Lecoq, Dupin and Sergeant Cuff never won the heart of the public; but Sherlock Holmes became, almost at once, a figure of international notoriety; he has been parodied unceasingly, and taken a permanent place in the language; and the detectives who have followed him—Trent, Father Brown, Hanaud, Poirot, etc.—are attempts to vary him which do not quite succeed in replacing him.

During the present century, and especially since the World War, the vogue of the detective story has been enormous. Its popularity (like that of the "Cross Word Puzzle") may be due to the demand for some "compensation" for tired brains which find the occupations of daily life an insufficient stimulus, and have despaired of tackling the riddle of the universe. The morbidity of the modern sex novel also tends to drive back the reading public to ingenious story-telling. On the whole, detective fiction seems to be a recreation to the author as to the reader, and some of the most successful examples of it belong to the bibliography of writers who would prefer to be remembered by more enduring work. A. E. W. Mason has condescended to the art, with the happiest results, in *At the Villa Rose* and *The House of the Arrow*. G. K. Chesterton's Father Brown, distantly modelled on Fr. John O'Connor of Bradford, as Sherlock Holmes was distantly modelled on Dr. Bell of Edinburgh, has pressed the *roman policier* into the service of metaphysics and even of theology. A. A. Milne's *Red House Mystery* is a paragon worthy of a great humourist. E. C. Bentley may yet go down to posterity as a *homo unius libri* if he does not attempt to repeat the success of *Trent's Last Case*, the despair and the model of all detective writers.

Of the authors who have made their name since the war, Mrs. Agatha Christie probably deserves the palm for ingenuity (in *The Mysterious Affair at Styles*, for example, and *The Murder of Roger Ackroyd*); but some of her work is disfigured by sensationalism. On the other side, there is a tendency to undue laboriousness of detail in the writing of F. W. Croft and R. Austin Freeman. G. D. H. Cole's work may be taken as a good example of detective writing which is conscientious without being pedantic. In general it seems fair to observe that authors who only write one or two detective stories (Philip Macdonald, for example, author of *The Rasp*) are more readable than those professional craftsmen who turn out a new book with every season.

(R. A. K.)

Other Mystery Stories.—Riddle stories are mystery tales based on a question and answer which in no way call for or depend upon the work of a detective, either professional or amateur. Among the finest riddle stories are Poe's "The Oblong Box," and "The Gold Bug." In more modern times Kipling proved himself a master in this line, with "The Sending of Dana Da," and "His Wedded Wife." Collins' "The Woman in White" is a riddle story, and a perfect example is Frank Stockton's "The Lady or the Tiger." De Quincey's "The Avenger" and Bulwer's "A Strange Story" are classic riddle stories. The distinguishing feature of the riddle story is that the reader shall be confronted with a number of mysterious facts of which the explanation is reserved till the end. Aroused curiosity, sustained suspense and an unexpected but satisfactory final revelation are the chief requisites for the plot.

The ghost story, strictly speaking, is a tale of the supernatural. From the days of the Witch of Endor, the superhuman personage has held an exalted place in literature. Shakespeare, Dickens and Washington Irving number among their characters ghosts who became famous. Kipling and Marion Crawford have added to the

¹See *Archiv für Religionswiss.* (1906), article by Salomon Reinach.

list. The ghost story must fall into one of two classes. Either the ghost is a spectre or it is a machination of a living person. But in either case, fear is the dominant note, and ghost stories include apparitions or other hair-raising horrors that fill readers with shivers of delight. "The Horla" by Maupassant and "What Was It?" by Fitz James O'Brien are typical and famous ghost stories. Kipling's "They" is in the front rank, as is Henry James's "The Turn of the Screw." "The Shadow on the Wall" by Mary E. Wilkins is a perfect example.

From the ages of antiquity the puzzle has held its own among mental activities; and puzzle, in its broader sense, includes all branches of mystery stories. The dictionaries define puzzle as "a riddle, toy or contrivance which is designed to try one's ingenuity." This is the crux of the mystery story. It is designed to try the reader's ingenuity at re-solution, and as an athlete rejoices in his muscular prowess, so the mental acrobat revels in concentrating all his brain power on an analytical problem.

(C. Ws.)

MYSTICISM, a phase of thought, or rather perhaps of feeling, which from its very nature is hardly susceptible of exact definition. It appears in connection with the endeavour of the human mind to grasp the divine essence or the ultimate reality of things, and to enjoy the blessedness of actual communion with the Highest. The first is the philosophic side of mysticism; the second, its religious side. The first effort is theoretical or speculative; the second, practical. The thought that is most intensely present with the mystic is that of a supreme, all-pervading, and indwelling power, in whom all things are one. Hence the speculative utterances of mysticism are always more or less pantheistic in character. On the practical side, mysticism maintains the possibility of direct intercourse with this Being of beings—intercourse, not through any external media such as an historical revelation, oracles, answers to prayer, and the like, but by a species of transfusion or identification, in which the individual becomes in very truth "partaker of the divine nature." God ceases to be an object to him, and becomes an experience.

Universality.—In the writings of the mystics, ingenuity exhausts itself in the invention of phrases to express the closeness of this union. Mysticism differs, therefore, from ordinary pantheism in that its inmost motive is religious; but, whereas religion is ordinarily occupied by a practical problem and develops its theory in an ethical reference, mysticism displays a predominately speculative bent, starting from the divine nature rather than from man and his surroundings, taking the symbolism of religious feeling as literally or metaphysically true, and straining after the present realization of an ineffable union. The union which sound religious teaching represents as realized in the submission of the will and the ethical harmony of the whole life is then reduced to a passive experience, to something which comes and goes in time, and which may be of only momentary duration. Mysticism, it will be seen, is not a name applicable to any particular system. It may be the outgrowth of many differing modes of thought and feeling. Most frequently it appears historically, in relation to some definite system of belief, as a reaction of the spirit against the letter. When a religion begins to ossify into a system of formulas and observances, those who protest in the name of heart-religion are not unfrequently known by the name of mystics. At times they merely bring into prominence again the ever-fresh fact of personal religious experience; at other times mysticism develops itself as a powerful solvent of definite dogmas. Mysticism appears in various phases in all the higher religions known to history. Its distinctive characteristics emerge in the religions of India and Persia as well as in the faith of Islam. These subjects are dealt with elsewhere; but its relation to Judaism and the religions of Greece requires special mention here. For opposite reasons, neither the Greek nor the Jewish mind lent itself readily to mysticism: the Greek, because of its clear and sunny naturalism; the Jewish, because of its rigid monotheism and its turn towards worldly realism and statutory observance. It is only with the exhaustion of Greek and Jewish civilization that mysticism becomes a prominent factor in Western thought. It appears, therefore, contemporaneously with Christianity, and is a sign of

the world-weariness and deep religious need that mark the decay of the old world. Whereas Plato's main problem had been the organization of the perfect state, and Aristotle's intellect had ranged with fresh interest over all departments of the knowable, political speculation had become a mockery with the extinction of free political life, and knowledge as such had lost its freshness for the Greeks of the Roman Empire. Knowledge is nothing to these men if it does not show them the infinite reality which is able to fill the aching void within. Accordingly, the last age of Greek philosophy is theosophical in character, and its ultimate end is a practical satisfaction. Neoplatonism seeks this in the ecstatic intuition of the ineffable One. The systematic theosophy of Plotinus and his successors does not belong to the present article, except so far as it is the presupposition of their mysticism; but, inasmuch as the mysticism of the mediaeval Church is directly derived from Neoplatonism through the speculations of the pseudo-Dionysius, Neoplatonic mysticism fills an important section in any historical review of the subject.

Neoplatonism.—Neoplatonism appears in the first half of the 3rd century, and has its greatest representative in Plotinus. He develops the Platonic philosophy into an elaborate system by means of the doctrine of emanation. The One, the Good, and the Idea of the Good were identical in Plato's mind, and the Good was therefore not deprived of intelligible essence. It was not separated from the world of ideas, of which it was represented as either the crown or the sum. By Plotinus, on the contrary, the One is explicitly exalted above the *νοῦς* and the "ideas"; it transcends existence altogether (*ἐπέκεινα τῆς οὐσίας*), and is not cognizable by reason. Remaining itself in repose, it rays out, as it were, from its own fullness an image of itself, which is called *νοῦς*, and which constitutes the system of ideas of the intelligible world. The soul is in turn the image or product of the *νοῦς*, and the soul by its motion begets corporeal matter. The soul thus faces two ways—towards the *νοῦς*, from which it springs, and towards the material life, which is its own product. Ethical endeavour consists in the repudiation of the sensible; material existence is itself estrangement from God. (Porphyry tells us that Plotinus was unwilling to name his parents or his birthplace, and seemed ashamed of being in the body.) Beyond the *καθάρσεις*, or virtues which purify from sin, lies the further stage of complete identification with God (*οὐκ ἔξω ἀμαρτίας εἶναι, ἀλλὰ θεὸν εἶναι*). To reach the ultimate goal, thought itself must be left behind; for thought is a form of motion, and the desire of the soul is for the motionless rest which belongs to the One. The union with transcendent deity is not so much knowledge or vision as ecstasy, coalescence, *contact* (*ἔκστασις, ἄλκωσις, ἀφή, Ennead., vi. 9. 8-9*). But in our present state of existence the moments of this ecstatic union must be few and short.

It will be seen from the above that Neoplatonism is not mystical as regards the faculty by which it claims to apprehend philosophic truth. It is first of all a system of complete rationalism; it is assumed, in other words, that reason is capable of mapping out the whole system of things. But, inasmuch as a God is affirmed beyond reason, the mysticism becomes in a sense the necessary complement of the would-be all-embracing rationalism. The system culminates in a mystical act, and in the sequel, especially with Iamblichus and the Syrian Neoplatonists, mystical practice tended more and more to overshadow the theoretical groundwork.

Dionysius the Areopagite.—It was probably about the end of the 5th century, just as ancient philosophy was dying out in the schools of Athens, that the speculative mysticism of Neoplatonism made a definite lodgment in Christian thought through the literary forgeries of the pseudo-Dionysius (see DIONYSIUS THE AREOPAGITE). The doctrines of Christianity were by that time so firmly established that the Church could look upon a symbolical or mystical interpretation of them without anxiety. The author of the *Theologia mystica* and the other works ascribed to the Areopagite proceeds, therefore, to develop the doctrines of Proclus with very little modification into a system of esoteric Christianity. God is the nameless and supra-essential One, elevated above goodness itself. Hence "negative theology," which ascends from the creature to God by dropping one after another

every determinate predicate, leads us nearest to the truth. The return to God (*ἐλπίς, θέωσις*) is the consummation of all things and the goal indicated by Christian teaching. The same doctrines were preached with more of churchly fervour by Maximus the Confessor (580-622).

The West.—St. Maximus represents almost the last speculative activity of the Greek Church, but the influence of the pseudo-Dionysian writings were transmitted to the West in the 9th century by Erigena, in whose speculative spirit both the scholasticism and the mysticism of the middle ages have their rise. Erigena translated Dionysius into Latin along with the commentaries of Maximus, and his system is essentially based upon theirs. In Erigena mysticism has not yet separated itself in any way from the dogma of the Church. There is no revulsion, as later, from dogma as such, nor is more stress laid upon one dogma than upon another; all are treated upon the same footing, and the whole dogmatic system is held, as it were, in solution by the philosophic medium in which it is presented. No distinction is drawn, indeed, between what is reached by reason and what is given by authority; the two are immediately identical for Erigena. In this he agrees with the speculative mystics everywhere, and differentiates himself from the scholastics who followed him. The chief representatives of scholasticism aim at demonstrating that the content of revelation and the teaching of reason are identical, but this is only an equation of two things which have been dealt with on the supposition that they are separate. Mysticism, on the other hand, is marked on its speculative side by even an overweening confidence in human reason; and this is pre-eminently visible in the work of Erigena. Nor need this be wondered at if we consider that the unity of the human mind with the divine is its underlying presupposition. Hence where reason is discarded by the mystic it is merely reason overleaping itself; it occurs at the end and not at the beginning of his speculations. Even then there is no appeal to authority; nothing is accepted from without. The appeal is still to the individual, who, if not by reason then by some higher faculty, claims to realize absolute truth and to taste absolute blessedness.

Anti-dialectical.—Mysticism first appears in the mediaeval Church as the protest of practical religion against the predominance of the dialectical spirit. It is so with Bernard of Clairvaux (1090-1153), who condemns Abelard's distinctions and reasonings as externalizing and degrading the faith. St. Bernard's mysticism is of a practical cast, dealing mainly with the means by which man may attain to the knowledge and enjoyment of God. Reason has three stages, in the highest of which the mind is able, by abstraction from earthly things, to rise to *contemplatio* or the vision of the divine. More exalted still, however, is the sudden *ecstatic* vision, such as was granted, for example, to Paul. This is the reward of those who are dead to the body and the world. Asceticism is thus the counterpart of medieval mysticism; and, by his example as well as by his teaching in such passages, St. Bernard unhappily encouraged practices which necessarily resulted in self-delusion. Love grows with the knowledge of its object, he proceeds, and at the highest stage self-love is so merged in love to God that we love ourselves only for God's sake or because God has loved us. "As the little water-drop poured into a large measure of wine seems to lose its own nature entirely and to take on both the taste and the colour of the wine; or as iron heated red-hot loses its own appearance and glows like fire; or as air filled with sunlight is transformed into the same brightness so that it does not so much appear to be illuminated as to be itself light—so must all human feeling towards the Holy One be self-dissolved in unspeakable wise, and wholly transfused into the will of God. For how shall God be all in all if anything of man remains in man? The substance will indeed remain, but in another form, another glory, another power" (*De diligendo Deo*, c. 10).

Mysticism was more systematically developed by Bernard's contemporary Hugh of St. Victor (1096-1141). The Augustinian monastery of St. Victor near Paris became the headquarters of mysticism during the 12th century. It had a wide influence in awakening popular piety, and the works that issued from it

formed the textbooks of mystical and pietistic minds in the centuries that followed. Hugh's pupil, Richard of St. Victor, declares, in opposition to dialectic scholasticism, that the objects of mystic contemplation are partly above reason, and partly, as in the intuition of the Trinity, contrary to reason. He enters at length into the conditions of ecstasy and the yearnings that precede it. Bonaventura (1221-1274) was a diligent student of the Victorines, and in his *Itinerarium mentis ad Deum* maps out the human faculties in a similar fashion. He introduces the terms "apex mentis" and "scintilla" (also "synderesis" or, *συντήρησις*) to describe the faculty of mystic intuition. Bonaventura runs riot in phrases to describe the union with God, and his devotional works were much drawn upon by mystical preachers.

Theology of the Heart.—From the 12th and 13th centuries onward there is observable in the different countries of Europe a widespread reaction against the growing formalism and worldliness of the Church and the scandalous lives of many of the clergy. Men began to feel a desire for a theology of the heart and an unworldly simplicity of life. In the beginning of the 13th century the foundation of the Dominican and Franciscan orders furnished an ecclesiastical and regular means of supplying the same wants, and numerous convents sprang up at once throughout Germany. The German mind was a peculiarly fruitful soil for mysticism, and a number of women appear about this time, combining a spirit of mystical piety and asceticism with sturdy reformatory zeal directed against the abuses of the time. Even before this we hear of the prophetic visions of Hildegard of Bingen (a contemporary of St. Bernard) and Elizabeth of Schönau. In the 13th century Elizabeth of Hungary, the pious landgravine of Thuringia, assisted in the foundation of many convents in the north of Germany. (For an account of the chief of these female saints see the first volume of W. Preger's *Geschichte der deutschen Mystik*.) Mechthild of Magdeburg appears to have been the most influential, and her book *Das fließende Licht der Gottheit* is important as the oldest work of its kind in German. It proves that much of the terminology of German mysticism was current before Eckhart's time. Mechthild's clerico-political utterances show that she was acquainted with the "eternal gospel" of Joachim of Floris. Joachim had proclaimed the doctrine of three world-ages—the kingdom of the Father, of the Son, and of the Spirit. The reign of the Spirit was to begin with the year 1260, when the abuses of the world and the Church were to be effectually cured by the general adoption of the monastic life of contemplation.

Very similar to this in appearance is the teaching of Amalric of Bena (d. 1207); but, while the movements just mentioned were reformatory without being heretical, this is very far from being the case with the mystical pantheism derived by Amalric from the writings of Erigena. His followers held a progressive revelation of God in the ages of the Father, Son and Holy Spirit. Just as the Mosaic dispensation came to an end with the appearance of Christ, so the sacraments of the new dispensation have lost their meaning and efficacy since the incarnation of God as Holy Spirit in the Amalricans. With this opposition to the Church they combine a complete antinomianism, through the identification of all their desires with the impulses of the divine Spirit. Amalric's teaching was condemned by the Church, and his heresies led to the public burning of Erigena's *De divisione naturae* in 1225.

Eckhart.—In Meister Eckhart (? 1260-1327) the German mind definitively asserts its pre-eminence in the sphere of speculative mysticism. Eckhart was a distinguished son of the Church; but in reading his works we feel at once that we have passed into quite a different sphere of thought from that of the churchly mystics; we seem to leave the cloister behind and to breathe a freer atmosphere. The scholastic mysticism was, for the most part, practical and psychological in character. It was largely a devotional aid to the realization of present union with God; and, so far as it was theoretical, it was a theory of the faculties by which such a union is attainable. But in Eckhart the attitude of the churchman and traditionalist is entirely abandoned. His system enables him to give a profound significance to the doctrines

of the Church; but, instead of the system being accommodated to the doctrines, the doctrines—and especially the historical facts—acquire a new sense in the system, and often become only a mythical representation of speculative truth.

The political circumstances of Germany in the first half of the 14th century were in the last degree disastrous. The war between the rival emperors, Frederick of Austria and Louis of Bavaria, and the interdict under which the latter was placed in 1324 inflicted extreme misery upon the unhappy people. From some places the interdict was not removed for twenty-six years. Men's minds were pained and disquieted by the conflict of duties and the absence of spiritual consolation. The country was also visited by a succession of famines and floods, and in 1348 the Black Death swept over Europe like a terrible scourge. In the midst of these unhappy surroundings religion became more inward in men of real piety and the desire grew among them to draw closer the bonds that united them to one another. Thus arose the society of the Friends of God (*Gottesfreunde*) in the south and west of Germany, spreading as far as Switzerland on the one side and the Netherlands on the other. They formed no exclusive sect. They often took opposite sides in politics and they also differed in the type of their religious life; but they uniformly desired to strengthen one another in living intercourse with God. Among them chiefly the followers of Eckhart were to be found. Such were Heinrich Suso of Constance (1295-1366) and Johann Tauler of Strasbourg (1300-1361), the two most celebrated of his immediate disciples. It was doubtless one of the Friends who sent forth anonymously from the house of the Teutonic Order in Frankfurt the famous handbook of mystical devotion called *Eine deutsche Theologie*, first published in 1516 by Luther.

Jan van Ruysbroeck (1294-1381), the father of mysticism in the Netherlands, stood in connexion with the Friends of God, and Tauler is said to have visited him in his seclusion at Groenendael near Brussels. He was decisively influenced by Eckhart, though there is noticeable occasionally a shrinking back from some of Eckhart's phraseology. Ruysbroeck's mysticism is more of a practical than a speculative cast. He is chiefly occupied with the means whereby the *unio mystica* is to be attained, whereas Eckhart dwells on the union as an ever-present fact, and dilates on its metaphysical implications. Towards the end of Ruysbroeck's life, in 1378, he was visited by the fervid lay-preacher Gerhard Groot (1340-1384), who was so impressed by the life of the community at Groenendael that he conceived the idea of founding a Christian brotherhood, bound by no monastic vows, but living together in simplicity and piety with all things in common, after the apostolic pattern. This was the origin of the Brethren of the Common Lot (or Common Life). The first house of the Brethren was founded at Deventer by Gerhard Groot and his youthful friend Florentius Radewyn; and here Thomas à Kempis (*q.v.*) received his training. Similar brother-houses soon sprang up in different places throughout the Low Countries and Westphalia, and even Saxony.

Mysticism and the Reformation.—It has been customary for Protestant writers to represent the mystics of Germany and Holland as precursors of the Reformation. In a sense this is true. But it would be false to say that these men protested against the doctrines of the Church in the way the Reformers felt themselves called upon to do. There is no sign that Tauler, for example, or Ruysbroeck, or Thomas à Kempis had felt the dogmatic teaching of the Church jar in any single point upon their religious consciousness. Nevertheless, mysticism did prepare men in a very real way for a break with the traditional system. Mysticism instinctively recedes from formulas that have become stereotyped and mechanical. On the other hand its claim for spiritual freedom was soon to be found in opposition also to the Reformers.

The wild doctrines of Thomas Münzer and the Zwickau prophets, merging eventually into the excesses of the Peasants' War and the doings of the Anabaptists in Münster, first roused Luther to the dangerous possibilities of mysticism as a disintegrating force. He was also called upon to do battle for his principle against men like Caspar Schwenkfeld (1490-1561) and Sebastian Franck (1500-1545), the latter of whom developed a system of

pantheistic mysticism, and went so far in his opposition to the letter as to declare the whole of the historical element in Scripture to be but a mythical representation of eternal truth. Valentin Weigel (1533-1588), who stands under manifold obligations to Franck, represents also the influence of the semi-mystical speculation that marked the transition from scholasticism to modern times. The final breakdown of scholasticism as a rationalized system of dogma may be seen in Nicolas (or Nicolaus) of Cusa (1401-1464), who insists that all real apprehension of God is by way of a "knowledge above knowledge." The influence of later mediaeval mysticism is seen in Jacob Boehme (1575-1624).

Other Forms of Mysticism.—Mysticism did not cease within the Catholic Church at the Reformation. In St. Theresa (1515-1582) and John of the Cross the counter-reformation can boast of saints second to none in the calendar for the austerity of their mortifications and the rapture of the visions to which they were admitted. But, as was to be expected, their mysticism moves in that comparatively narrow round, and consists simply in the heaping up of these sensuous experiences. The speculative character has entirely faded out of it, or rather has been crushed out by the tightness with which the directors of the Roman Church now held the reins of discipline. The gloom and harshness of these Spanish mystics are absent from the tender, contemplative spirit of François de Sales (1567-1622); and in the quietism of Mme. Guyon (1648-1717) and Miguel de Molinos (1627-1696) there is again a sufficient implication of mystical doctrine to rouse the suspicion of the ecclesiastical authorities.

In the 17th century mysticism is represented in the philosophical field by the so-called Cambridge Platonists, and especially by Henry More (1614-1687), in whom the influence of the Kabbalah is combined with a species of Christianized Neoplatonism. Pierre Poiret (1646-1719), an ardent student of Tauler and Thomas à Kempis, exhibits a violent reaction against the mechanical philosophy of Descartes, and especially against its consequences in Spinoza. The first influence of Boehme was in the direction of an obscure religious mysticism. J. G. Gichtel (1638-1710), the first editor of his complete works, became the founder of a sect called the Angel-Brethren. All Boehme's works were translated into English in the time of the Commonwealth, and regular societies of Boehmenists were formed in England and Holland. Later in the century he was much studied by the members of the Philadelphian Society, John Pordage, Thomas Bromley, Jane Lead, and others. The mysticism of William Law (1686-1761) and of Louis Claude de Saint Martin in France (1743-1803), who were also students of Boehme, is of a much more elevated and spiritual type. The "Cherubic Wanderer," and other poems, of Johann Scheffler (1624-1677), known as Angelus Silesius, are more closely related in style and thought to Eckhart than to Boehme.

The religiosity of the Quakers, with their doctrines of the "inner light" and the influence of the Spirit, has decided affinities with mysticism; and the autobiography of George Fox (1624-1691), the founder of the sect, proceeds throughout on the assumption of supernatural guidance. Stripped of its definitely miraculous character, the doctrine of the inner light may be regarded as the familiar mystical protest against formalism, liberalism, and scripture-worship. Swedenborg, though selected by Emerson in his *Representative Men* as the typical mystic, belongs rather to the history of spiritualism than to that of mysticism as understood in this article. He possesses the cool temperament of the man of science rather than the fervid Godward aspiration of the mystic proper; and the speculative impulse which lies at the root of this form of thought is almost entirely absent from his writings. Accordingly, his supernatural revelations resemble a course of lessons in celestial geography more than a description of the beatific vision.

Analysis.—The term mysticism is often extended by popular usage and philosophical partisanship to the whole activity of the German idealistic thinkers who followed Kant; but this looseness of phraseology only serves to blur important distinctions. However absolute a philosopher's idealism may be, he is erroneously styled a mystic if he moves towards his conclusions only by the

patient labour of the reason. Hegel therefore, to take an instance, can no more fitly be classed as a mystic than Spinoza can. It would be much nearer the truth to take both as types of a thoroughgoing rationalism. In either case it is of course open to anyone to maintain that the apparent completeness of synthesis really rests on the subtle intrusion of elements of feeling into the rational process. But in that case it might be difficult to find a systematic philosopher who would escape the charge of mysticism; and it is better to remain by long-established and serviceable distinctions.

So, again, when Récéjac defines mysticism as "the tendency to draw near to the Absolute in moral union by symbolic means," the definition, as developed by him, is one which would apply to the philosophy of Kant. Récéjac's interesting work, *Les Fondements de la connaissance mystique* (Eng. trans. 1899), though it touches mysticism at various points, and quotes from mystic writers, is in fact a protest against the limitations of experience to the data of the senses and the pure reason to the exclusion of the moral consciousness and the deliverances of "the heart." But such a position is not describable as mysticism in any recognized sense. On the other hand, the term is in place where the movement of revulsion from a mechanical philosophy takes the form rather of immediate assertion than of reasoned demonstration, and where the writers, after insisting generally on the spiritual basis of phenomena, either leave the position without further definition or expressly declare that the ultimate problems of philosophy cannot be reduced to articulate formulas. Examples of this are men like Novalis, Carlyle and Emerson, in whom philosophy may be said to be impatient of its own task.

Modern Studies.—Study of the subject may be said to begin with Dean Inge's Bampton Lectures on Christian Mysticism (1899). It has since been pursued along the parallel routes of psychology, history and philosophy of religion, with the result that the claim of mysticism to be regarded as a genuine form of human experience is justified. These aspects of mysticism cannot rigidly be separated, or indeed understood in isolation, each being of vital importance to the rest.

William James, in his epoch-making Gifford Lectures on *The Varieties of Religious Experience* (1902), originated the serious study of mysticism, especially from the psychological point of view, and attempted to discover its relation to other forms of consciousness. Although based on material chosen from too restricted a field, the publication of this book revolutionised the attitude of students towards religious psychology. The conception of the subconscious was now first used to provide an explanation and sanction for the ecstatic and other abnormal phenomena found in connection with mysticism, and an attempt was made to distinguish the accompaniments of genuine religious apprehension from their pathological imitations.

These researches have continued vigorously, especially in America and France. Pratt's *Religious Consciousness* (1921) represents the matured result of the movement started by James. Considerable advance has been made towards the correlation and better understanding of such types as the prophet, visionary and religious revivalist, in all of whom a strong mystical impulse is commonly at work. The hostile study of mysticism from the psychological standpoint has its chief exponent in J. H. Leuba, and to some extent in the work of experimental psychologists such as P. Janet, whilst an approach midway between the philosophical and psychological is provided by Bucke's *Cosmic Consciousness*, a curious work which has exercised considerable influence. Delacroix's sympathetic but penetrating analyses of the evolution of the great mystics have shed much light on the psychological characteristics of religious genius. Valuable studies of the nature of mystical contemplation, and restatement in modern terms of its processes, have been produced by Roman Catholic scholars, the best being those of Père Poulain, S.J.

Influence of Psychology.—The psychological study of mystical phenomena has illuminated many historical problems, especially those connected with prophecy and the origins of religious movements. The treatment of the subject in such works as Heiler's *Das Gebet* and *Der Katholizismus* or Brémont's monumental *Histoire du Sentiment religieux en France*, is symptomatic of the

changed outlook. Material available for students of historical mysticism has been much enriched. Good texts and translations of many masterpieces of European mysticism have appeared, with valuable studies such as those of Abbot Butler and Rufus Jones, based on the historical method.

The changed outlook of physical science, the new understanding of its limitations and the marked revolt from 19th-century materialism, have brought about a *rapprochement* between mysticism and philosophy. Inge's *Philosophy of Plotinus* (1918) and Otto's widely discussed essay *Das Heilige* (The Idea of the Holy, 1924) show different aspects of the reaction of philosophy to mysticism. But this is also felt in the pure metaphysics of Wittgenstein, and in the inimical attitude of Croce and his school. The greatest and ultimately most influential expositions of the place of mysticism in theistic philosophy, and its limitations and rightful relation with other aspects of knowledge, are Von Hügel's *Mystical Element of Religion* and *Eternal Life*. These books have affected all modern religious thinkers, and may provide the starting-point of a critical realism harmonising the mystical, moral and intellectual approaches to reality. In America, Hocking's *Meaning of God in Human Experience* is probably the most important philosophic contribution to this subject.

Modern Practical Mysticism.—The first quarter of the 20th century saw, especially in France, a revival of genuine Christian mysticism; possibly the beginning of what later historians may recognise as a "mystical epoch." Its most impressive document is the *Spiritual Journal* of the lady known as Lucie-Christine (1844-1908), a record which bears comparison with the historical classics of mysticism. Its most striking product is the career of the hermit saint of the Sahara, Charles de Foucauld (1858-1916). These stand out among a number of more obscure personalities, such as Elizabeth de la Trinité (1880-1906) and Madeleine Sémer (1874-1921), all of whom claim and describe with a conviction and sobriety compelling respect the characteristic mystical experience and certitude. From India, the autobiography of the saintly Hindu theist Maharshi Devendranath Tagore (1817-1905), and the experiences of the Christian convert Sadhu Sundar Singh (born 1889), whose career and personality have made a widespread impression, provide unspoilt examples of first-hand mysticism, and deepen the sense of unity in the spiritual intuitions.

The revived interest in mysticism has had popular results in several directions. It has seemed to endorse the shallow eclecticism in which many escape the difficulties of belief. Its superficial peculiarities have been exploited by theosophists and other apostles of eccentric religiosity. It has produced numerous bastard cults, mostly hailing from America though often wearing Oriental disguise; cults mainly compounded of pantheism, quietism and crude autosuggestion, and offering a "mystical religion" to those seeking a spiritual home full of modern conveniences and devoid of discipline. On the other hand, its spirit has affected for good the literature and activity of the organised Churches; shifting the emphasis from tradition to experience, and bringing back into focus those mysterious realities which religious symbols and institutions seek to express.

schichte der Deutschen Mystik (1874-93). See also articles on the greater mystical writers named. (A. S. P.-P.; E. UN.; X.)

MYTH AND RITUAL. The fundamental association of myth with ritual emerges clearly in the view of Robertson Smith, that in all antique religions mythology takes the place of dogma. He thought that mythology was no essential part of ancient religion for it had no sacred sanction and no binding force on the worshippers. Belief in myths was not obligatory as a part of true religion. He argued that, from the outset, ritual and practical usage were strictly speaking, the sum total of ancient religions. Political institutions are older than political theories and in like manner religious institutions are older than religious theories. Dr. Cook (*Religion of the Semites*, 3rd Edn. 1927) points out that myth and ritual often act upon each other. Some, he thinks, are based upon misunderstandings, are explanations of explanations, are the product of the more intelligent and sophisticated individuals, or have been purified of earlier crudities, while fancy and imagination have transformed them. While myths are specifically of personal interest, in general they appeal to the different types of mind in mixed communities. The views of Robertson Smith have assumed a more precise shape in the argument of Professor Radcliffe Brown that "it is necessary to take into account the explanations given by the natives themselves. Although these explanations are not of the same kind as the scientific explanations that are the objects of research, yet they are of great importance as data. Like the civilized man of Western Europe, the savage of the Andamans seeks to rationalise his behaviour; being impelled to certain actions by mental dispositions of whose origin and real nature he is unaware, he seeks to formulate reasons for his conduct, or even if he does not when left to himself, he is compelled to when the enquiring ethnologist attacks him with questions. Such a reason as is produced by this process of rationalisation is rarely, if ever, identical with the psychological cause of the action that it justifies, yet it will nearly always help us in our search for the cause. At any rate, the reason given as explaining the action is so intimately connected with the action itself that we cannot regard any hypothesis as to the meaning of a custom as being satisfactory unless it explains, not only the custom, but also the reasons that the natives give for following it. . . . Tales that might seem merely the products of a somewhat childish fancy are very far indeed from being merely fanciful and are the means by which the Andamanese express and systematise their fundamental notions of life and nature and the sentiments attaching to these notions." (A. R. Brown, *Andaman Islanders*, pp. 234 and 330, 1922.)

The process of symbolic thought is of important reference to and criticism of the interpretation of "the beliefs of savages as being the result of attempts to understand natural facts such as dreams, death, birth, etc. Such writers assume that the savage is impelled by the same motive that so strongly dominates themselves, the desire to understand—scientific curiosity, and that such beliefs as animism or totemism are in the nature of scientific hypothesis, invented to explain the facts of dreaming and of death on the one hand, and of conception and birth on the other. If this view of the nature of primitive thought were correct it would be impossible to conceive how such inconsistencies as those that were met with among the Andamanese could be permitted. On the view that the myths of primitive society are merely the result of an endeavour to express certain ways of thinking and feeling about the facts of life which are brought into existence by the manner in which life is regulated in society, the presence of such inconsistencies need not in the least surprise us, for the myths satisfactorily fulfil their function, not by any appeal to the reasoning powers but by appealing, through the imagination, to the mind's affective dispositions." (A. R. Brown, *The Andaman Islanders*, 1922, p. 397.)

Malinowski insists that "the function of myth, briefly, is to strengthen tradition and endow it with a greater value and prestige by tracing it back to a higher, better, more supernatural reality of ancient events." From myth spring the epic romance and tragedy. Myth, therefore, touches the deepest desires of man—his fears, his hopes, his passions, his sentiments as it validates the

social order, justifies the existing social scheme and ranges from expressions of sheer artistry to legalism. (*Myth in Primitive Psychology*, 1927.)

MYTHOLOGY, the science which examines *μῦθος*, myths or legends of cosmogony and of gods and heroes. Mythology is also used as a term for these legends themselves. Thus when we speak of "the mythology of Greece" we mean the whole body of Greek divine and heroic and cosmogonic legends. When we speak of the "science of mythology" we refer to the various attempts which have been made to explain these ancient narratives. Very early indeed in the history of human thought men awoke to the consciousness that their religious stories were much in want of explanation. The myths of civilized peoples, as of the Aryans of India and the Greeks, contain two elements, the rational and what to modern minds seems the irrational. The rational myths are those which represent the gods as beautiful and wise. The real difficulties of mythology spring from the irrational element, which to modern minds appears senseless or repellent.

Classical mythology is discussed under GREEK RELIGION; ROMAN RELIGION and such articles as ODYSSEUS; THESEUS; ORPHEUS. For other mythology consult ANIMISM; TOTEMISM; LYCANTHROPY; METEMPSYCHOSIS and similar articles; see RELIGION, ARTICLES ON.

MYXINE, a genus of hag-fishes, containing a single species, *M. glutinosa* of the north Atlantic. (See HAGFISH; CYCLOSTOMATA.)

MYXOEDEMA, the medical term for a constitutional disease (see METABOLIC DISEASES) due to the degeneration of the thyroid gland, and occurring in adults; cretinism is essentially the same condition appearing in early childhood. There are two forms, myxoedema proper and operative myxoedema (*cachexia strumipriva*). (1) Myxoedema has been termed "Gull's Disease" from Sir William Gull's observations in 1873. Women are more often the victims than men, in a ratio of six to one. It frequently affects members of the same family and may be transmitted through the mother; it has been observed sometimes to follow exophthalmic goitre. The symptoms are a marked increase in bulk and weight of the body, puffy appearance of skin which does not pit on pressure, the line of the features becoming obliterated and getting coarse and broad, the lips thick and nostrils enlarged, with loss of hair, subnormal temperature and marked mental changes. There is striking slowness of thought and action, the memory becomes defective, and the patient becomes irritable and suspicious. In some instances the condition progresses to that of dementia. The thyroid gland itself is diminished in size, and may become completely atrophied and converted into a fibrous mass. The untreated disease is progressive, but the course is slow and the symptoms may extend over 12 to 15 years, death from asthenia or tuberculosis being the most frequent ending. (2) Symptoms similar to the above may follow complete removal of the thyroid gland. Kocher of Berne found that, in the total removal of the gland by operation, out of 408 cases operative myxoedema occurred in 69, but it is thought that if a small portion of the gland is left, or if accessory glands are present, these symptoms will not develop. The treatment of myxoedema, like that of cretinism, is by administration of thyroid extract. (See ANIMAL EXTRACTS.)

N In all known alphabets the letter N has stood in close connection with M, the particular form of one being generally reflected in the other. Semitic *𐤍* (*nun*) and Greek *ν* (*nu*) are its predecessors. In the inscriptions from Thera the form was consistently *Ν*. Other forms were *Λ* from Corinth and *Ν* in the Ionic alphabet of Abu-Simbel. In the Lydian alphabet the form was *𐌕*, Etruscan has sometimes the curious form *𐌕* corresponding to its five-stroked *𐌕* (*M*). In the Italic alphabets the form of the letter followed that of *M*, being found in Umbrian as *𐌕*, in Oscan as *𐌕* and in Faliscan as *𐌕*. The Latin forms were *N* and *N*.

The minuscule cursive form of the 6th century was *𐌕*, probably accounted for by the writing of the letter without taking the pen from the paper commencing at the top of the left-hand

DEVELOPMENT OF THE LETTER "N" FROM THE EARLIEST TIMES TO THE PRESENT DAY

vertical stroke. This would cause the oblique stroke to rise from left to right instead of being downward in direction. The Carolingian hand developed the rounded minuscule form *𐌕*. From this derives the modern minuscule.

The sound that the letter has represented throughout its history is the dental nasal, the nasals being of all sounds the least liable to change. (B. F. C. A.)

NABATAEANS, a people of ancient Arabia, whose settlements gave the name of Nabatene to the border-land between Syria and Arabia from the Euphrates to the Red sea. The his-

tory of the Nabataeans cannot be carried back beyond 312 B.C., at which date they were attacked without success by Antigonos I. (*Cyclops*) in their mountain fortress of Petra.

The Nabataeans were Arabs—as their proper names show—who came under Aramaic influence. They wrote a letter to Antigonos "in Syriac letters," and Aramaic continued to be the language of their coins and inscriptions when the tribe grew into a kingdom, and profited by the decay of the Seleucids to extend its borders northward over the more fertile country east of the Jordan. They occupied Haurān, and about 85 B.C. their king Aretas (Hārithath) became lord of Damascus and Coele-Syria. Allies of the first Hasmonaeans in their struggles against the Greeks (i. Macc. v. 25, ix. 35; 2 Macc. v. 8), they became the rivals of the Judaeen dynasty in the period of its splendour, and a chief element in the disorders which invited Pompey's intervention in Palestine. The Roman arms were not very successful, and King Aretas retained his whole possessions, including Damascus, as a Roman vassal. (cf. 2 Cor. xi. 32). As "allies" of the Romans the Nabataeans continued to flourish throughout the first Christian century. Their power extended far into Arabia, particularly along the Red sea; and Petra was a meeting-place of many nations, though its commerce was diminished by the rise of the Eastern trade-route from Myoshoormus to Coptos on the Nile. A sober, acquisitive, orderly people, wholly intent on trade and agriculture (Strabo, xvi. 4), they might have long been a bulwark between Rome and the wild hordes of the desert but for the short-sighted cupidity of Trajan, who reduced Petra and broke up the Nabataean nationality (A.D. 105). (See SEMITIC LANGUAGES.) (W. R. S.; S. A. C.)

NABBES, THOMAS (b. 1605), English dramatist, was born in humble circumstances in Worcestershire. He entered Exeter College, Oxford, in 1621, but left the university without taking a degree, and about 1630 began a career in London as a dramatist.

Nabbes's plays were collected in 1639; and *Microcosmus* was printed in Dodsley's *Old Plays* (1744). All his works, with the exception of his continuation of Knolles's history, were reprinted by A. H. Bullen in his *Old English Plays* (second series, 1887). See also F. G. Fleay, *Biog. Chron. of the English Drama* (1891).

NABHA, an Indian State, within the Punjab. Area 928 sq.m. Pop. (1921) 263,334. Its territories are scattered; one section with twelve separate tracts, lies among the territories of Patiala and Jind, in the East and South of the Punjab; the other section is in the extreme South-East. Nabha is one of the Sikh states, founded by a member of the Phulkian family, which established its independence about 1763. In 1807-1808, the raja obtained British protection against threatened encroachments of Ranjit Singh. During the Mutiny in 1857 the raja showed distinguished loyalty, and was rewarded by grants of territory to the value of over £10,000. The State also did good service during the World War. It was in 1929 under the administration of a Council of Regency, the chief being a minor. The estimated gross revenue is £190,000.

The town of Nabha, founded in 1755, has a station on the North-Western railway. Pop. (1921) 14,750.

NÁBIGHA DHUBYÁNÍ [Ziyād ibn Mu'awīyya] (6th and 7th centuries), Arabian poet, was one of the last pre-Islamic poets.

He lived at the courts of Hira and Ghassân. In Hira he remained under Mondhir (Mundhir) III., and his successor. After a sojourn at the court of Ghassân, he returned to Hira under Nu'mân. He was compelled to flee to Ghassân, but returned again about 600. About 605 he withdrew to his own tribe. The date of his death is uncertain. He wrote mainly eulogies and satires concerned with the strife of Hira and Ghassân, and of the Bani Abs and the Bani Dhubyân. He is one of the six pre-Islamic poets whose poems were collected before the middle of the 2nd century of Islam.

His poems have been edited by W. Ahlwardt in the *Diwans of the six ancient Arabic Poets* (London, 1870), and separately by H. Derenbourg (Paris, 1869, a reprint from the *Journal asiatique* for 1868).

NABIS, tyrant of Sparta, seized the throne after Sparta's heavy defeat by the Achaean League in 207 B.C. He seems to have put into practice the "four points" of the revolutionary programme of the day, abolition of debt, division of land, confiscation of personal property and liberation of slaves, though he does not appear to have tackled the Helot problem very completely. Whether he was the monster of cruelty represented by Polybius it is difficult to say. No revolutionary leader gets fair play from contemporary historians as a rule, and few revolutionary leaders can afford very gentle measures. In any case, he carried out more thoroughly the aims of Agis and Cleomenes, and extended his system to Argos, which was put into his hands by Philip V. in 198. The Achaeans under Philopoemen first attacked him in 201, and defeated him at Scotitas. Later in 195 B.C. after the conclusion of the war with Philip the Romans under Flamininus turned their attention to the affairs of Greece. The League was unanimous for war against Nabis, and Flamininus duly undertook it. Nabis organized a vigorous defence, and raised an army of 10,000 from Sparta with the help of the enfranchised Helots. After some desultory fighting and a good deal of negotiation, Nabis obtained peace at the price of losing Argos and some harbours, and the internal affairs of Sparta were left undisturbed. As soon as the Romans had gone Nabis was embroiled with the Achaeans again. He was eventually murdered by some Aetolian auxiliaries, and Philopoemen ruthlessly suppressed one of the few whole-hearted attempts at social revolution in Greek history.

See Plutarch, *Philopoemen*; Polyb. xiii.-xx.; Paus. iv. viii.; Liv. 31-35; W. W. Tarn, in *The Hellenistic Age* (Cambridge, 1923), and *Hellenistic Civilization* (1927).

NABOB, a corruption of word *nawab*, a native Indian ruler. In the 18th century, it was sarcastically applied to Anglo-Indians who returned with fortunes from the East.

NABUA, a municipality (with administration centre and 20 *barrios* or districts) in the extreme south of the province of Camarines Sur, Luzon, Philippine Islands, on the Bikol river, a short distance north of Lake Bato. Pop. (1918) 19,314. It is connected with the provincial capital, Naga, by road to Iriga and thence by railroad. Nabua is the centre of an agricultural district which produces rice, corn, sugar and pepper. In 1918, it had 538 household industry establishments with output valued at 127,400 pesos. The language spoken is Bikol.

NACHTIGAL, GUSTAV (1834-1885), German explorer in Central Africa, son of a Lutheran pastor, was born at Eichstedt in the Mark of Brandenburg, on Feb. 23, 1834. After studying medicine at the universities of Halle, Würzburg and Greifswald he practised for some years as a military surgeon. He went to Algiers and Tunis in search of health, and took part, as a surgeon, in several expeditions into the interior. The king of Prussia sent him on a mission to the sultan of Bornu in 1869. He visited Tibesti and Borku, regions of the central Sahara then unknown to Europeans. From Bornu he went to Bagirmi, and, proceeding by way of Wadai and Kordofan, arrived at Khartum in the winter of 1874. His journey, graphically described in his *Sahara und Sudan* (3 vols., 1879-89), placed the intrepid explorer in the front rank of discoverers. Nachtigal was consul-general for the German empire at Tunis until 1884, when he was sent by Bismarck to West Africa as special commissioner, ostensibly to enquire into the condition of German commerce, but really to annex territories to the German flag. As the result of his mission Togoland and Cameroon

were added to the German empire. On his return voyage he died at sea off Cape Palmas on April 20, 1885.

Nachtigal's travels are summarized in *Gustav Nachtigal's Reisen in der Sahara und im Sudan*, by Dr. Albert Frankel (Leipzig, 1887).

NADEN, CONSTANCE CAROLINE WOODHILL (1858-1889), English author, was born at Edgbaston, Birmingham, on Jan. 24, 1858, her father being an architect. In 1881 she published *Songs and Sonnets of Springtime*; in 1887, *A Modern Apostle, and other Poems*. W. E. Gladstone included her, in an article in the *Speaker*, among the foremost English poetesses of the day. She died on Dec. 23, 1889. After 1876 she had paid increasing attention to philosophy, with her friend Dr. Robert Lewins, and the two had formulated a system of their own, which they called "Hylo-Idealism." Her main ideas on the subject are contained in a posthumous volume of her essays (*Induction and Deduction*, 1890), edited by Dr. Lewins.

NADIA, a district of British India, in the Presidency division of Bengal. Area, 2,778 sq.m.; pop. (1921), 1,487,572. Standing at the head of the Gangetic delta, Nadia is an alluvial plain, the level of which has been raised by deposits of silt, so that it is subject to inundation only in years of high flood. Along the north-eastern boundary flows the main stream of the Ganges or Padma, of which the remaining rivers of the district are offshoots. The Bhagirathi on the eastern border, and the Jalangi and the Matabhanga meandering through the centre of the district, are the chief of those offshoots, called distinctively the "Nadia rivers." In former times the Nadia rivers afforded a regular means of communication between the Ganges and the seaboard; but the levels of the river beds have risen and, except in the rains, the rivers have diminished into shallow streams. The land no longer receiving a fertilizing deposit of silt, the productivity of the soil has been reduced; this, with obstructed drainage and consequent epidemics of fever, has caused a gradual loss of population. Rice is the staple crop; but the district is not as a whole fertile, the soil being sandy. The manufacture of molasses from the juice of date palms is the principal industry.

The headquarters of the district are at Krishnagar (pop. 22,309), which contains the residence of the Maharajah of Nadia and a Government college; a local industry is the moulding of clay figures, which display considerable art. The battlefield of Plassey is situated in this district.

NADIA or **NABADWIP** was formerly situated on the east bank of the Bhagirathi, which has since changed its course. Pop. (1921), 15,584. It is celebrated for its capture by the Mohammedans at the end of the 12th century, for the sanctity and learning of its pundits, and as the birthplace of Chaitanya, the Vaishnava reformer of the 16th century. Its Sanskrit schools, called *tols*, are well known and of ancient foundation.

NADIR, a term used in astronomy for the point in the heavens exactly opposite to the zenith, the zenith and nadir being the two poles of the horizon. (Arabic *naḍir*, "opposite to," used elliptically for *naḍir-es-semt*, "opposite to the zenith.") It is thus used figuratively of the lowest point in a career.

NAEGELI, KARL WILHELM VON (1817-1891), Swiss botanist, was born on March 26, 1817, near Zürich. He studied botany under A. P. de Candolle at Geneva, graduated at Zürich in 1840, then devoted himself to the microscopical study of plants. Soon after graduation he became *Privatdozent* and subsequently professor extraordinary, in the University of Zürich. He was later called to fill the chair of botany in the universities of Freiburg (1852), and Munich (1858), where he died on May 10, 1891.

Naegeli made many important and varied discoveries. He extended Robert Brown's discovery of the nucleus to the principal families of Cryptogams and asserted that it is present in all plants. He investigated the "mucous layer" (*Schleimschicht*) in cells and showed this to be the living matter of the cell. This discovery was made independently and at the same time by Hugo von Nohl (1805-1872), who called the living substance "protoplasm." Naegeli also investigated the mode of growth in a large number of plants belonging to the algae, mosses, liverworts and angiosperms. He discovered the spermatozooids and antheridia of ferns. He also wrote papers on the anatomy of vascular plants

and on the structure, development and various forms of starch grains. In his last book he introduced the idea of a substance which he called "idioplasm" as the definite material basis of heredity.

Among his more important contributions to science were a series of papers in the *Zeitschrift für wissenschaftliche Botanik* (1844-46); *Die neuern Algensysteme* (1847); *Gattungen einzelliger Algen* (1849); *Pflanzenphysiologische Untersuchungen* (1855-58), with C. E. Cramer; *Beiträge zur wissenschaftlichen Botanik* (1858-68); a number of papers contributed to the Royal Bavarian academy of sciences, forming three volumes of *Botanische Mitteilungen* (1861-81); and, finally, his volume, *Mechanisch-physiologische Theorie der Abstammungslehre*, published in 1884.

More detailed accounts of Naegeli's life and work are to be found in *Nature*, Oct. 16, 1891, and in *Proc. Roy. Soc.*, vol. II.

NAEVIUS, GNAEUS (c. 264-? 194 B.C.), Latin epic poet and dramatist. From a phrase in Gellius (i. 24. 1.) it has been inferred that he was born in a colony in Campania, but it seems just as probable that he was a Roman citizen. He served in the First Punic War. His career as a dramatic author began with the exhibition of a drama in or about the year 235, and continued for 30 years. Towards the close he incurred the hostility of some of the nobility, especially, it is said, of the Metelli, by the attacks which he made upon them on the stage, and at their instance he was imprisoned (Plautus, *Mil. Glor.* 211). After writing two plays during his imprisonment, in which he is said to have apologized for his former rudeness (Gellius iii. 3. 15), he was liberated through the interference of the tribunes of the commons; but he had shortly afterwards to retire from Rome (in or about 204) to Utica. His epic may have been written during his exile. Probably his latest composition was the epitaph already referred to, written like the epic in Saturnian verse:—

"Immortales mortales si foret fas flere,
Flerent divae Camenae Naevium poetam;
Itaque postquam est Orci traditus thesaurus
Obliiti sunt Romae loquar lingua Latina!"

Like Livius, Naevius professed to adapt Greek tragedies and comedies to the Roman stage. Among the titles of his tragedies are *Aegisthus*, *Lycurgus*, *Andromache* or *Hector Proficiscens*, *Equus Trojanus*, the last named being performed at the opening of Pompey's theatre (55). But he also produced at least two specimens of the *fabula praetexta* (national drama) one founded on the childhood of Romulus and Remus (*Lupus* or *Alimonium Romuli et Remi*), the other called *Clastidium*, which celebrated the victory of M. Claudius Marcellus over the Celts (222). But it was as a writer of comedy that he was most famous. He is placed in the canon of the grammarian Volcacius Sedigitus third (immediately after Caecilius and Plautus) in the rank of Roman comic authors. He is there characterized as ardent and impetuous in character and style. He is also appealed to as a master of his art in one of the prologues of Terence. His comedy, like that of Plautus, seems to have been rather a free adaptation of his originals than a rude copy of them, as those of Livius probably were, while the titles of most of them, like those of Plautus, are Latin. He used the stage, as it had been used at Athens, as a political arena, and his sympathies are strongly popular and anti-Senatorial. Among the few lines still remaining from his lost comedies, we seem to recognize the idiomatic force and rapidity of movement characteristic of the style of Plautus. There is also found that love of alliteration which is a marked feature in all the older Latin poets. In one considerable comic fragment attributed to him—the description of a coquette—there is great truth and shrewdness of observation. But we find no trace of the exuberant comic power and geniality of his great contemporary.

He was not only the oldest native dramatist, but the first author of an epic poem (*Bellum Punicum*)—which, by combining the representation of actual contemporary history with a mythical background, may be said to have created the Roman type of epic poetry. The earlier part of it treated of the mythical adventures of Aeneas, and the later part of the events of the First Punic War in the style of a metrical chronicle. This poem is the first appear-

¹⁴If it were permitted that immortals should weep for mortals, the divine Camenae would weep for Naevius the poet; for since he hath passed into the treasure-house of death men have forgotten at Rome how to speak in the Latin tongue."

ance in Roman literature of the belief in the foundation of Rome by Aeneas. The few remaining fragments produce the impression of vivid and rapid narrative, to which the flow of the native Saturnian verse, in contradistinction to the weighty and complex structure of the hexameter, was naturally adapted.

Fragments (dramas) in L. Müller, *Livi Andronici et Cn. Naevii Fabularum Reliquiae* (1885), and (*Bellum Punicum*) in his edition of Ennius (1884); monographs by E. Klussmann (1843); M. J. Berchem (1861); D. de Moor (1877); F. Marx, *Naevius* (Leipzig, 1911); Mommsen, *History of Rome*, bk. iii., ch. 14. On Virgil's indebtedness to Naevius and Ennius, see V. Crivellari, *Quae praecipue hausit Vergilius ex Naevio et Ennio* (1889).

NAEVUS, in medicine, a non-malignant tumour composed of newly-formed blood channels. Three varieties, capillary, venous, and arterial, are described, but the walls of the blood channels differ widely in their microscopic appearances from the corresponding normal vessels. The capillary naevus consists of tortuous small channels, often with relatively thick walls; it may be slightly raised above the surface of the skin (and then bleeds readily on slight injury) or flat and purple in colour, when it constitutes the "port-wine stain" or "mother's mark." The venous naevus consists of large irregular channels with very thin walls and is usually found in the subcutaneous tissue or the liver. Capillary and venous naevi are common on the face and may extend in size rapidly. The arterial naevus is rare; it pulsates and the channels may be emptied by pressure. Most naevi are so small as to call for no special treatment; if they take on growth or are initially so large as to cause disfigurement they may be treated by electro-puncture or by application of radium or carbonic-acid snow. The object desired is coagulation of the contained blood and replacement of the tumour by scar tissue. In the case of a large naevus, especially if venous, treatment may take weeks but great cosmetic improvement is usually possible.

NAGA, a municipality (with administration centre and 15 *barrios* or districts), capital of the province of Camarines Sur, Luzon, Philippine Islands, a short distance south of San Miguel bay, on the Bikol river and on the railway leading from Manila into Albay province. It lies in a fertile agricultural region and can be reached by small steamers from Manila via the Bikol river. Pop. (1918), 9,396. In 1918 it had 19 manufacturing establishments with output valued at 192,400 pesos; and 22 household industry establishments with output valued at 10,300 pesos. Of the eight schools, six were public. The language spoken is Bikol. Juan de Salcedo had reached this vicinity as early as 1573, and shortly afterwards, by order of Gov. Francisco de Sande, a Spanish town called Nueva Cáceres was founded on the site of the native town of Naga, and became the capital of the old province of Camarines. In 1919, the united province was divided into Camarines Norte and Camarines Sur, Naga becoming the capital of the latter.

NAGA HILLS, a district of British India in the Surma Valley and Hill Districts division of Assam. It forms part of the mountainous borderland lying between the Brahmaputra valley and Upper Burma. Area, 3,115 sq.m.; pop. (1921) 160,960. The whole country forms a wild expanse of forest, mountain and stream: Japvo (9,890 ft.), south of Kohima, is the highest mountain in Assam. Coal is known to exist in many localities, as well as iron ore and petroleum; a coal mine is worked by the Nazira Coal Company. The administrative headquarters of the district are at Kohima, at which is stationed a battalion of the Assam Rifles. When the British first came into contact with them, the Nagas were blood thirsty savages with a passion for head-hunting. The necessity of protecting British subjects from their ferocious raids led to punitive expeditions and the gradual occupation of the hills. A frontier district was first formed in 1866; the twelfth and last expedition came to a successful issue in 1880, after which it was decided that the Naga Hills should be administered as British territory. In 1904 some territory of the eastern Angamis, the most warlike tribe, was annexed, and during the operations of 1917-19 against the Kukis of Manipur a further tract was occupied, bringing the boundary up to Burma, north of Manipur. Since 1880 the Nagas have given no serious trouble and have been pacified and to some extent civilized.

(X.)

The Nagas.—This name is used for a group of tribes inhabiting the northern part of the hills dividing Assam from Burma. Within the group are tribes of mixed origin, varying cultures, and very different physique and appearance, but having enough in common to make it generally possible to say, within the area indicated, whether a given tribe is Naga (as distinct from Kachin, Kuki, Kachari, etc.) or not.

Every sort of political organization is found from the autocracy of tabued chiefs (Konyak tribes) though gerontocracy (Ao tribe) to purest democracy (Angami tribe). Socially patrilineal exogamy is everywhere the rule, but there are indications of the pre-existence of matrilineal and perhaps totemistic systems and of leviritical polyandry. Dual organization (*q.v.*) is found and communal houses for the unmarried. Some tribes (*e.g.*, Sema, Chang) practice polygyny; monogamy is more common, divorce being easy and frequent. Inheritance of land always passes in the male line.

Agriculture is practised by all tribes, some growing rice on elaborately built up and irrigated terraces (Angami, Tangkhul), others growing it dry, and others using millet, *Coix lachryma* or taro as the staple crop, with maize, sorghum, yams and sago as subsidiary. Millet is often grown on dry terraces among pollarded alders; cotton is grown, cattle are kept and numbers of mithun (*bos frontalis*), which has generally but not everywhere displaced the buffalo. Dogs are reared for food (*see* CYNOTHERAPY) as well as hunting. Fishing is practised, particularly with the use of intoxicants which kill or incapacitate the fish. Manufactures and the arts include weaving (on simple tension looms), dyeing, pot-making, blacksmith's work and rough wood-carving. Material culture shows many links with Indonesia and Melanesia, and the northern tribes make huge wooden xylophones, membraneless "drums" often suggestive of dug-out canoes with carved figure-heads, which are beaten to raise an alarm or celebrate important events. The prevailing weapon is the throwing-spear, but cross-bows are used by some tribes, also guns. Music and dancing are most highly developed in the southern tribes, but are everywhere popular. The languages, which belong to the Tibeto-Burmese family, are diverse and excessively numerous, nearly every village having its own dialect. All dialects are tonal and agglutinative.

See Mills, *The Ao Nagas* (1926, bibl.).

(J. H. H.)

NAGASAKI, a town on the south-west of the island of Kyushu, Japan, in 32° 44' N., 129° 51' E., with 189,071 (1925) inhabitants. The first port of entry for ships coming from the south or the west to Japan, it lies at the head of a beautiful inlet some 3 m. long, which forms a splendid anchorage, and is largely used by ships coming to coal and by warships. Marine products, coal and cotton goods are the chief exports, and raw cotton, iron, as well as other metals and materials used for shipbuilding, constitute the principal imports. The most important industries of the town are represented by the engine works of Aka-no-ura, three large docks and a patent slip, the property of the Mitsubishi Company. Nagasaki is a noted shipbuilding port and coaling station. The coal is obtained chiefly from Takashima, an islet 8 m. S.E. of the entrance to the harbour, and in lesser quantities from two other islets, Naka-no-shima and Ha-shima, which lie about 1 m. farther out.

Nagasaki owed its earliest importance to foreign intercourse. Originally called Fukae-no-ura (Fukae Bay), it was included in the fief of Nagasaki Kotaro in the 12th century, and from him it took its name. But it remained an insignificant village until the 16th century, when, becoming the headquarters of Japanese Christianity, and subsequently the sole emporium of foreign trade in the hands of the Dutch and the Chinese, it developed considerable prosperity. The opening of the port of Moji (*q.v.*) for export trade deprived Nagasaki of its monopoly as a coaling station.

NAGPUR, a town in India, in Jodhpur state of Rajputana. Pop. (1921) 10,227. Nagaur is surrounded by a wall more than 4 m. in circuit. It has given its name to a famous breed of cattle.

NAGINA, a town of British India, in Bijnor district of the United Provinces, 48 m. N.W. of Moradabad. Pop. (1921) 18,736. There is considerable trade in sugar, besides manufactures of guns,

glassware (especially bottles for the use of pilgrims carrying the sacred water of the Ganges from Hardwar) and ebony wares.

NAGOYA, the capital of the province of Owari, Japan, on the great trunk railway of Japan, 235 m. from Tokyo and 94 m. from Kioto. Pop. (1925), 768,558. It is the third of the chief cities in Japan. It lies near the head of the shallow Isenumi bay, about 30 m. from the port of Yokkaichi, with which it communicates by light-draught steamers and by rail. The castle of Nagoya, erected in 1610, never suffered in war, but in modern times became a military depot; the interior contains much splendid decoration. The religious buildings of Nagoya include a very fine Buddhist temple, Higashi Hongwanji. Nagoya is one of the great seats of the pottery trade; 13½ m. distant are the potteries of Seto, where the first glazed pottery made in Japan was produced by Kato Shirozaemon, after a visit to China in 1229. Cotton mills have been established, and an extensive business is carried on in the embroidery of handkerchiefs. Another of its celebrated manufactures is *arimatsushibori*, or textile fabrics (silk or cotton), dyed so as to show spots in relief from which the colour radiates. It was the birthplace of *cloisonné* enamelling in Japan.

NAGPUR, a city, district and division of British India in the Central Provinces, of which it is the capital. The old capital of the Bhonsla dynasty has expanded out of all recognition between 1852, when it came under British rule, and the present day. Its population, 84,000 in 1872, had expanded to 145,193 at the census of 1921. From being the terminus of a branch line it has become an important railway centre, nearly half way between Bombay and Calcutta and on the new north and south railway route between Madras and Delhi. It is also connected by a 2 ft. 6 in. gauge railway with Chindwara and Chanda. It is the commercial, as well as the administrative capital of the Province and the centre of education, being the seat of the university and the headquarters of both the Anglican and Roman Catholic dioceses and of important Protestant missions.

The whole area is dominated by the hill and fort of Sitabaldi, overlooking the civil station on the west, the city proper on the east and north, and the suburbs of Sitabaldi and Craddock Town to the south. This hill is the scene of the famous battle of Nov. 1817 where a small British force of less than 1,500 strong repulsed the Mahratta army of 20,000. The only regular troops in Nagpur now are those stationed in this fort, but it is the headquarters of the auxiliary force. Besides the mills, there is an important hand-weaving industry carried on by Koshtis, producing fine fabrics and silk-bordered cloths. There is also a large community of Momins or Mohammedan weavers.

The DISTRICT OF NAGPUR has an area of 3,834 square miles and a population of 792,521 (1921) as compared with 630,346 in 1872. It contains in all 12 towns and is situated on an extension of the Berar plain eastwards of the Wardha river. In the western portion Deccan trap overlies sandstone formation. In the eastern portion the sandstone is broken up by granite and the juxtaposition of these formations, which meet at Sitabaldi, makes the geology of the district interesting. In the north and north-east there are valuable deposits of manganese ore which are worked by three large companies and several individual concessionaires. The sacred hill of Ramtek in the north-east, with its gleaming white temples, is a landmark for miles around. The drainage of the east is to the Wainganga in Bhandara, and of the west to the Wunna and Wardha rivers. The plain is broken up in the west by ranges of flat-topped hills, but there are many plains, fertile valleys and pockets of rich land.

Agriculture is varied, Kunbis being the great cultivating Mahratta caste, but Raghvis and Kirars, immigrants from Upper India, are also excellent cultivators. To the west the cropping is mainly cotton and *juar*, in the centre and south wheat, linseed, and pulses are the chief staples. On the north-east and south-east there is a considerable area of rice. There are fine betel leaf plantations and the district is famous for its orange gardens. Government forests cover 500 square miles, mostly concentrated in the reserves along the Pench river on the north, but isolated blocks of not much value are scattered over the rest of the district.

NAGYKANIZSA (nöd'kân-its'ah), a town of west Hungary, county Zala, a railway junction and agricultural market town. It has large flour-mills, distilleries, breweries and vegetable-preserving works, manufactures bricks and trades in cereals and cattle. It was once a powerful fortress, important during the attacks of the Turks who held it 1600–90. Pop. (1920) 30,037.

NAGYSZOMBAT: see TRNAVA.

NAHUATL. The Nahuatl or Nahuatl language was that spoken in and about Anahuac—the high valley of Mexico. It forms, with Shoshonean and Piman, the Uto-Aztecan speech family. The centre of the Nahuatl peoples was on the south-east end of the great central mesa of Mexico, where the Toltecs were the most important prehistoric and the Aztecs the best known historic representatives. Nahuatl groups also extended southward into Morelos and Guerrero, eastward along the coast to Colima, and northward again into Jalisco, where they abutted on Piman-Sonoran peoples. Except at this point, the related Piman and Nahuatl groups were not in contact, but were separated by the alien Tarascan and Otomi. South-east of Mexico and Puebla, the Atlantic lowlands from Vera Cruz to Tabasco were Nahuatl; here were the Olmecs and others, north of the Zapotec and Mixe-Zoque, and bordering in the east on Mayan peoples. The Nahuatl territory is continuous thus far. Beyond, there were detached areas in Chiapas, Guatemala, San Salvador, Nicaragua, and even Panama. These represented dispersal migrations, some early, some later. Nahuatl speech seems to have been fairly uniform, but was further standardized to the dominant Aztec by Spanish influence. It is still the mother tongue of over half a million Mexican Indians, while probably as many more, and many whites, are partially acquainted with it. Through the Toltecs and Aztecs, the Nahuatl peoples share with the Maya the distinction of having been the bearers of highest culture in aboriginal America.

NAHUM (Hebrew for "rich in comfort [is God]"), an Old Testament Prophet. Of the Prophet himself, all that is known is the statement of the title that he was an Alkoshite. But the locality denoted by the designation is quite uncertain. The original heading of Nahum's prophecy is contained in the second part of the superscription: "(the book of) the vision of Nahum the Alkoshite." The first part ("Oracle concerning Nineveh") is a late editorial insertion, but correctly describes the main contents of the little book.

Contents.—Chapters i. and ii. The prophecy against Nineveh in its present form really begins with chapter ii. 1, followed immediately by v. 3, and readily falls into three parts, viz. (a) ii. 1, 3–10; (b) ii. 11–13; and (c) iii. Here (a) describes the assault on Nineveh. The city is mentioned by name in ii. 8 (9 Heb. text), its capture and sack; (b) contains an oracle of Yahweh directed against the king of Assyria; (c) again gives a vivid picture of war and desolation which are to overtake and humiliate Nineveh, as they have already overtaken No-Amon (i.e., Egyptian Thebes, vv. 8–10). The absence of distinctly religious motive is remarkable.

Chapter i. forms the exordium of the prophecy of doom against Nineveh. Its tone is exalted, and a fine picture is given of Yahweh appearing in judgment: The effects of the divine anger on the physical universe are forcibly described (vv. 3–6); on the other hand, God cares for those "that put their trust in Him" (v. 7), but overwhelms His enemies (vv. 8–12a). In the following verses (12b–15) the joyful news is conveyed to Judah of the fall of the oppressor.

Regarding Chapter i. and ii. 2 (=i. and ii. 1, 3, Heb. Text) there has been much discussion in recent years. It was long ago noticed that traces of an alphabetic acrostic survive in this section of the book. In vv. 12b, 13 and (certainly) v. 15 (=ii. 1 Heb.) Judah appears to be addressed. The text of i. 1–15, ii. 1–2 has been reconstructed by H. Gunkel and G. Bickell so as to form a complete alphabetic psalm with contents of an eschatological character, and is regarded by them as a later addition to the book. It is generally held by scholars that i. 1–8, 13, 15, and ii. 2 certainly do not proceed from Nahum (i. 9–12 may, however, belong to the prophet). No satisfactory solution has been reached.

Date.—The date of the composition of Nahum's prophecy must lie between 612, when Nineveh was captured and destroyed by the Babylonians and Medes, and the capture of Thebes (No-Amon), which is alluded to in iii. 8–10, in 663 B.C. On the whole a date somewhat near 612 is more probable. The poetry of the book is of a high order.

BIBLIOGRAPHY.—The *Commentaries* on the Minor Prophets, especially those of J. Wellhausen, D. W. Nowack and K. Marti (all German); G. A. Smith, *The Book of the Twelve Prophets* (2 vols.); A. B. Davidson, *Nahum, Habakkuk and Zephaniah* (Camb. Bible, 1896). (G. H. B.)

NAIADS, in Greek mythology the nymphs of wells, mountains and the sea, taking their name from the sphere of nature they represented. See NYMPH.

NAIDU, SAROJINI (1879–), Indian poet and feminist leader, eldest child of Dr. Aghorenath Chattopadhyay, a noted Bengali Brahman educationist and principal of the Nizam's college, Hyderabad, was born there on Feb. 13, 1879. Passing the matriculation examination of the Madras university at 12 she began writing English verse in her early teens. Sent to England in 1895 she studied at King's college, London, and Girton college, Cambridge. Her first volume of verse, "The Golden Threshold," was sponsored by Arthur Symonds, and the second, "The Bird of Time," by Edmund Gosse. "The Broken Wing" followed. These volumes have been translated into most of the Indian vernaculars and some into Continental languages, while portions of her verse have been set to music. Her marriage in 1898 to Dr. M. G. Naidu, a Rajput in the Nizam's service, caused some sensation and resentment in orthodox Hindu circles. Her address at the all-India Social Conference at Calcutta in 1905 marked the beginning of an active career as a most eloquent speaker on social and political questions, and as a leader in the women's movement in India. She gained the enthusiastic admiration of Indian students by her sympathy with their outlook and her power of thrilling presentation. She had some share in the militant women's suffrage movement in England before the World War, and this experience tended in later years to draw her to Gandhi's non-cooperation movement. A tour in South Africa in 1924, on behalf of the Indian settlers there, deepened her strong criticism of British rule in her own land. In 1925 she was the first Indian woman to preside over the annual Indian National Congress at Cawnpore. Her acute mental equipment was linked with a certain attractive mischievousness, but her eloquence was inspired and deepened by a strong burning patriotism. In 1928 she visited England and America, to lecture upon Indian affairs. (F. H. Br.)

NAIK or **NAYAK**, from a Sanskrit word meaning a leader, a title used in India in various senses. In the army it denotes a rank corresponding to that of corporal, and Hyder Ali of Mysore was proud of being called Haidar Naik, analogous to "le petit caporal" for Napoleon. It was also the title of the petty dynasties that arose in S. India on the downfall of the Hindu empire of Vijayanagar in the 16th century.

NAIL MANUFACTURE. Iron nails were commonly in use during the Roman occupation of Britain, large numbers having been found in places where they were wrought by the Romans. There is a striking similarity between the forged Roman nail (fig. 1) and the type of nail which is manufactured at the present time. The forging of nails was an industry of some importance in Great Britain up to the end of the 17th century, and only gave way before the advent of machinery and the cut and machine-headed nail. During the year 1927, 20,000 tons of wire nails were manufactured in Great Britain, whilst another 60,000 tons were imported.

Wire Nails.—The use of wire for nail making has completely revolutionized the method of manufacture; nails of this description are made so cheaply that they can be bought at almost the same price as the wire from which they are made.

Cut nails (fig. 1) are formed by being sheared out of plates or strips of iron, no other work being required to form the head. Wedge-shaped nails, sheared out of strip, with no definite head, are also sometimes used for fastening down flooring boards, etc., as in this form they do not damage the timber where the thick end enters. Cut nails with a central head (fig. 1) are also sheared

out of plate and at the same time passed continuously through machinery which forms the head.

Of nails manufactured in the cold state out of wire, in one large works alone no fewer than 300 different kinds, varying in section of wire, length, diameter, size and shape of head, point, etc., may be manufactured. Some of these shapes are shown in the accompanying figure (fig. 1): (a) and (f) show two different sizes of bright oval nails; (b) is the ordinary round wire nail; (c) is a round nail with a diamond head; (d) a round-headed nail made from square wire; (e) a rose-headed nail; (g) a tram nail; (h) a roofing nail; (i) is a special form of brad-head nail containing a centre punch mark which enables it to be driven by a centre punch beneath the surface of wood without damage to the wood; (j) and (l) are clout-headed nails; (k) is a short stiff nail with a strong head.

A screw nail (fig. 1) has also been invented which rotates as it is driven or forced into wood whether by hand or machine power. It is claimed that this nail drives more easily, has increased holding power, and in consequence of the screw cutting action does not split the wood whilst being driven in. This type of nail is extensively used as a heel pin for boots on account of its holding power. It is made from wire which is specially manufactured for the purpose, a screwed helix being formed on the surface of the wire as it passes along from the swift to the block, the nail being formed from this wire in the same way as for the ordinary nail.

One of the heaviest nails made both by heading and pointing in the cold state is the dog spike (fig. 1), used to hold down light tram rails. In the manufacture of heavy wire nails the pressure engendered to form the heads and points in the cold state is very great, and the machine must be of a corresponding strength. In the action of forming the point and head of the nail, the ham-

FIG. 1.—SPECIMENS OF VARIOUS KINDS OF NAILS

(A) Large oval, (B) common round, (C) round diamond, (D) square wire, (E) rose-headed, (F) small oval, (G) tramway, (H) roofing, (I) brad head, (J) clout head, (K) stiff strong head, (L) small clout head

mer or heading tool moves back with the nail as it is pushed forward to its required length, the side cutters then closing up on the wire to cut it off and to form a diamond point. Whilst this cutting is taking place the wire is very firmly gripped as will be seen by the "cording" marks or ribs at the neck of the nail.

Nails are made so rapidly that the movements can hardly be observed by the human eye, small nails being made at the rate of about 400 per minute. After they are formed they are collected and automatically conveyed to barrelling or tumbling machines in which they are shaken together for a period of 20 minutes to an hour. This process not only polishes the nails but trims off

any rough points. After the polishing the machines are emptied, the nails being automatically fed into bags or drums for despatch.

Staples.—As staples are a form of nail, their manufacture is usually carried on with that of nails. They are made both from bright and galvanized wire, and in all kinds of sizes. The three different forms of points on staples are illustrated (fig. 2), the names themselves indicating the difference in the style of point. The term "presser point" simply means that the point is so sharp and fine that the staple can be stuck into the wood by simple pressure previous to being hammered down.

FIG. 2.—FENCING STAPLES

The points are selected according to the kinds of wood used

used in the making of staples follow the same principle as in the making of the straight nail, the wire being automatically fed forward from the swift, and the operation of cutting and pointing being immediately followed by the bending of the wire into its required shape to form the staple.

(E. A. A.)

NAIL VIOLIN, a musical curiosity invented by Johann Wilde, a musician in the imperial orchestra at St. Petersburg. It consisted of a wooden soundboard about 1½ ft. long and 1 ft. wide, bent into a semicircle. In this soundboard were fixed a number of iron or brass nails of different lengths, tuned to give a chromatic scale, and the sound was produced by friction with a strong bow, strung with black horsehair.

NAINI TAL, a town and district of British India, in the Kumaon division of the United Provinces. The town is 6,400 ft. above sea-level. Pop. (1921) 10,392. Naini Tal is a popular sanatorium for the residents in the plains, and the summer headquarters of the government of the province. It is situated on a lake, surrounded by high mountains, and is subject to landslides; a serious catastrophe of this kind occurred in September 1880. There are several European schools, besides barracks and convalescent depôt for European soldiers.

The DISTRICT OF NAINI TAL comprises the lower hills of Kumaon and the adjoining Tarai or submontane strip. Area, 2,721 sq.m. Pop. (1921) 276,875. The district includes the Gagar and other foothills of the Himalayas, which reach an extreme height of nearly 9,000 ft. The Bhabar tract at their base consists of boulders from the mountains, among which the hill streams are swallowed up. Forests cover vast tracts of the hill-country and the Bhabar. Beyond this is the Tarai, moist and extremely unhealthy. Here the principal crops are rice and wheat. In the hills a small amount of tea is grown, and a considerable quantity of fruit.

NAINSOOK, a light and fine cotton fabric of the plain calico weave, and of texture similar to that of lawn and cambric. It is usually bleached and sometimes striped and checked and finished with a very soft feel for use as lingerie and underwear.

NAIRN, county town of Nairnshire, Scotland, on the Moray Firth, at the mouth of the Nairn, 15½ m. N.E. of Inverness by L.M.S.R. Pop. (1921) 4,474. The town, though of great age, shows no signs of this. It attracts many summer visitors by its good sea-bathing and golf-course. Salmon and deep-sea fishing are carried on. There is a good harbour with breakwater and pier. Nairn, originally called Invernarne (the mouth of the Nairn), was made a royal burgh by Alexander I. (d. 1124); but his charter having been lost, was confirmed by James VI. in 1589.

NAIRNE, CAROLINA, BARONESS (1766-1845), Scottish song writer, was born in the "auld hoose" of Gask, Perthshire, on Aug. 16, 1766. She was descended from an old family settled in Perthshire in the 13th century, and could boast of kinship with the royal race of Scotland. Her father, Laurence Oliphant, was one of the foremost supporters of the Jacobite cause, and she was named Carolina in memory of Prince Charles Edward. In 1806 she married W. M. Nairne, who became Baron Nairne in the year 1824. She brought out a collection of national airs set to appropriate words. To this collection, *The Scottish Minstrel* (1821-24), she contributed a large number of original

songs, adopting the signature "B. B."—"Mrs. Bogan of Bogan." The music was edited by R. A. Smith. She died at Gask on Oct. 26, 1845.

Among her most famous songs are: "The Laird o' Cockpen," "The Fife Laird," "John Tod," "Charlie is my darling," "Call'er Herrin'" and the "Land o' the Leal." For vivacity, genuine pathos and bright wit her songs are surpassed only by those of Burns.

For Lady Nairne's songs, see *Lays from Strathearn, arranged with Symphonies and Accompaniments for the Pianoforte by Finlay Dun* (1846); vol. i. of the *Modern Scottish Minstrel* (1857); *Life and Songs of the Baroness Nairne, with a Memoir and Poems of Caroline Oliphant the Younger*, edited by Charles Rogers (1869, new ed. 1886). See also T. L. Kington-Oliphant, *Jacobite Lairds of Gask* (1870).

NAIRNSHIRE, a north-eastern county of Scotland, bounded west and south by Inverness-shire, east by Elginshire and north by the Moray Firth. It has an area of 104,252 ac. and a coast line of 9 m., and is the fourth smallest county in Scotland. The seaboard, which is skirted by sandbanks dangerous to navigation, is lined by low dunes extending into Elginshire. Traces of old marine terraces are seen at elevations of 100, 50 and 25 ft. above present sea-level. Parallel with the coast there is a deposit of blown sand and gravel about 90 ft. high stretching inland for 4 or 5 m. This and the undulating plain behind are a continuation westward of the fertile Laigh of Moray. The lowland rocks are Old Red Sandstone, widely covered with glacial deposits consisting of lower and upper boulder clays, with later gravels forming ridges on the moorland between the rivers Findhorn and Nairn. From this region southward the land rises rapidly to the confines of Inverness-shire, where the chief heights occur. This higher land consists of the eastern, Dalriadan, or younger Highland schists, with associated granite masses. Several of the border hills exceed 2,000 ft. in elevation. The only rivers of importance are the Findhorn and the Nairn, both rising in Inverness-shire. The Findhorn after it leaves that county takes a mainly north-easterly direction down Strathearn for 17 m. and enters the sea to the north of Forres in Elginshire after a total course of 70 m. The Nairn, shortly after issuing from Strathnairn, flows towards the north-east for 12 m. out of its complete course of 38 m. and falls into the Moray Firth at the county town. There are eight lochs, all small: that of Clans contains crannogs, or ancient lake-dwellings. Nairnshire contains many beautiful woods and much picturesque scenery.

Industries.—The soil of the alluvial plain, or Laigh, is light and porous and careful cultivation has rendered it very fertile; and there is some rich land on the Findhorn. Although advanced methods of agriculture are in use, but a small proportion of the surface is capable of tillage, less than one quarter of the whole area being under crops. The hills are mostly covered with heath and pasture, suitable for sheep, and cattle are kept on the lower lying ground. A little sandstone quarrying and the sea and salmon fisheries of the Nairn are the only industries of the shire. The L.M.S. railway from Forres to Inverness crosses the north of the shire.

Population and Government.—The population numbered 8,790 in 1921. Nairn (pop. 4,474) is the county town and only royal burgh. Nairn and Moray shires combine to return one member to parliament. The shire forms a sheriffdom with Moray and a sheriff-substitute from Elgin sits also at Nairn.

History.—The country was originally peopled by the Gaelic or northern Picts. Stone circles believed to have been raised by them are found at several places, particularly in the valley of the Nairn. To the north of Dulsie Bridge is a monolith called the Princess Stone. Mote hills and stones with cup-markings are also common. Beyond the occasional finding of Roman coins, there is little evidence of effective Roman occupation. Columba and his successors made valiant efforts to Christianize the Picts, but it was long before their labours began to tell, although the saint's name was preserved late in the 19th century in the annual fair at Auldearn called "St. Colm's Market," while to his biographer Adamnan—corrupted into Evan or Wean—was dedicated the church at Cawdor, where an old Celtic bell also bears this name. By the dawn of the 10th century the Picts had been subdued with the help of the Norsemen, and Nairn, which was one of the

districts colonized by the Scandinavians, as part of the ancient province of Moray, soon afterwards became an integral portion of the kingdom of Scotland. Hardmuir, between Brodie and Nairn, is the heath where Macbeth is reputed to have met the witches. Territorially Moray was greatly contracted in the reign of David I., and thenceforward the history of Nairn merges in the main in that of the bishopric and earldom of Moray. (See ELOIN.) The thane of Cawdor was constable of the king's castle at Nairn, and when the heritable sheriffdom was established towards the close of the 14th century this office was also filled by the thane of the time.

NAIROBI, the capital of Kenya Colony, British East Africa, 330 m. by railway from Mombasa. It is built on the Athi plains, at the foot of the Kikuyu hills and is 5,452 ft. above sea level. It commands magnificent views of Kilimanjaro and Mt. Kenya. Pop. (1927) 13,145, of whom 3,565 were Europeans and 8,052 Indians. Nairobi is the seat of the Kenya Legislature and the headquarters of most of the European organizations in the colony. Nearly all the whites are British, and the town has most of the amenities of a European city. Both the standard and the cost of living are high. Laid out on a large scale, Nairobi has many fine private and public buildings, though still in a transitional stage (1929). The main thoroughfares are Government road, where numbers of shops and offices are owned by Indians, and Sixth avenue. The churches include an Anglican cathedral. In Sixth avenue are a cenotaph to the European soldiers who fell in the World War and opposite it a striking memorial, three figures on a single base, to the African troops and carriers who fell in the war. The African memorial was erected in 1928. Parklands is a residential suburb for Europeans. A natural history museum, in Kirk road, was opened in 1922. The Indian bazaar covers nine acres. The natives occupy a separate location with some 20,000 inhabitants. A branch railway runs to the foot of Mt. Kenya, and from Nairobi there is a motor-road to the navigable Nile at Nimule or Refaj. This is part of a motor road from Rhodesia to the Sudan (practicable in dry weather). Nairobi is governed by an elected municipality, with separate franchise rolls for Europeans and Indians.

The site of Nairobi was selected as the headquarters of the Uganda railway, and the first buildings were erected in 1899. For some time nearly all its inhabitants were railway officials and Indian coolies engaged in the construction of the line. In 1902 the surrounding highlands were found to be suitable for European settlement and Nairobi speedily grew in importance; in 1907 the headquarters of the administration were transferred to it from Mombasa. Nairobi had then 350 white inhabitants; in 20 years their number increased ten-fold. An ambitious town-planning scheme was adopted in 1927.

NAIVASHA, a lake, town and province, in Kenya colony. The lake, which is roughly circular with a diameter of some 13 m., lies 6,135 ft. high on the crest of the highest ridge in the eastern rift-valley between the Kikuyu escarpment (east) and the Mau escarpment (west). It is fed by the rivers Gilgal and Morendat which run in deep gullies, but has no known outlet. The water of the lake is fresh; the shore in many places is lined with papyrus. North and north-west the lake is closed in by the volcanic Buru hills; to the south towers the extinct volcano of Longonot. Hippopotami and otters frequent the lake, and on an island about 1 m. from the shore are large numbers of antelopes and other game. Naivasha was discovered in 1883 by Gustav Adolf Fischer (1848-86), and visited in the same year by Joseph Thomson, the Scottish explorer. The railway from Mombasa to Victoria Nyanza skirts the eastern side of the lake, and on the railway close to the lake is built the town of Naivasha, 6,230 ft. above the sea, 395 m. N. by rail from Mombasa. Naivasha province contains much land suitable for colonization by white men, and large areas have been leased to Europeans. The land is specially suitable for cattle and sheep rearing which is now in a very prosperous state.

NAIYADIS, the Nalyadis, or hunters, of Malabar are the dog-eaters and the lowest of the Hindu castes. Miserable specimens of humanity, they used to be excellent shots but the Arms

Act deprived them of their weapons and they now manufacture ropes, slings, mats and so on, with occasional cultivation. They have succession in the male line and adultery is abhorrent to them. Some have been converted to Christianity and others to Islam, the latter maintain themselves by begging from Mohammedans. Their chief priest, Muppon, is hereditary. He enquires into all matters affecting the community and can excommunicate a guilty person.

NAJARA, ISRAEL BEN MOSES, Hebrew poet, was born in Damascus and wrote in the latter part of the 16th century (1587-1599). He was inspired by the mystical school, and his poems are marked by their bold, sensuous images, as well as by a depth of feeling unequalled among the Jewish writers of his age. He often adapted his verses to Arabic and Turkish melodies. To tunes which had been associated with light and even ribald themes, Najara wedded words which reveal an intensity of religious emotion which often takes a form indistinguishable from love poetry. Some pietist contemporaries condemned his work for this reason; but this did not prevent many of his poems from attaining wide popularity and from winning their way into the prayer-book.

He published during his lifetime a collection of his poems, *Songs of Israel (Zemiroth Israel)*, in Safed in 1587; an enlarged edition appeared in Venice (1599-1600). Others of his poems were published at various times, and W. Bacher has described some previously unknown poems of Najara (*Revue des études juives*, Nos. 116 seq.).

NAJIBABAD, a town of British India, in the Bijnor district of the United Provinces. Pop. (1921) 18,504. It was founded in the middle of the 18th century by a Rohilla chief, and still contains several architectural monuments of Rohilla magnificence. There is considerable trade in timber, sugar and grain, and manufactures of metal-ware, shoes, blankets and cotton cloth.

NAKHICHEVAN, an autonomous republic of Russian Transcaucasia created in 1921, and linked administratively with the Azerbaijan S.S.R., from which it is, however, separated by a strip of Armenian territory. It is bordered on the south and south-west by Persia and on the north and east by the Armenian S.S.R. Area 6,524 sq.km. Pop. (1926) 103,600. Though the republic is small, its relief is varied. In the south-west it consists of the valley on the left bank of the Araxes river, which here forms the boundary between Russia and Persia, and along the left bank of which goes the railway loop from Tiflis on the Black sea-Caspian line, which links Armenia and the south of Azerbaijan with Baku, and from which a branch line goes to Tabriz from Dzfulpha in the Nakhichevan republic. The republic thus forms a centre for trade between Russia and Persia. From the valley of the Araxes the Armenian or Transcaucasian plateau rises to a height of about 10,000 feet.

The industries of the region are mainly silk weaving, cotton cleaning and wine production. In 1926 of the 16 former silk factories in Ordubad only 6 were working. The numerous small cotton-cleaning enterprises were re-organised after the revolution into two large government factories which produce 16,000 tons of cotton per annum. The former brandy distilling industry has not revived. A jam factory is under construction at Ordubad which provides for an output of 800 tons per annum. Of the mineral wealth in the republic, salt, lead, sulphur, arsenic, copper, sulphur pyrites and coal, only salt is exploited. In 1926 about 37,000 tons of salt were produced as against 43,000 in 1913. Curative arsenical and sulphur springs have been known to the native shepherds for centuries.

The population consists chiefly of Armenians and Azerbaijan Turks, with some Russians in the towns of Nakhichevan (pop. 8,946) and Ordubad (pop. 3,665). The number of schools and teachers has markedly increased, and there are Turkish, Armenian and Russian schools, but many children still receive no education. Grants from the Central Government of the U.S.S.R. provided for the building of a school, hospital and electric station in the town of Nakhichevan, and a grant was also made for the repair and rebuilding of the small factories, and the irrigation canals, and the development of cotton, silk and salt production. The region was important at an early date because it lay on the route from Teheran and Tabriz to Caucasia. It was laid waste by

the Persians in the 4th century, by the Seljuk Turks in the 11th century and by the Mongols in the 13th century. From that time until 1828, when by the peace of Turkman-chai it passed under Russian rule, it was frequently devastated during the wars between Persia, Armenia, Turkey and Russia. Its importance for trade and its great fertility helped it to recover after each of these disasters and after the more recent 1917-20 period of disorder and struggle.

NAKHICHEVAN, a Russian town, the administrative centre of the Nakhichevan S.S.R. in 39° 14' N., 45° 24' E., on the Kish-chai river and at the terminus of a short line linking it with the railway that runs north of the Araxes river and which is being prolonged to Baku (1928). The town is on a spur of the Karabagh mountains at an altitude of 2,940 ft. Pop. (1926) 8,946, mainly Tatars and Armenians. It has an electric plant, motor-driven flour mills and a leather factory. A little to the south-east of it, a branch railway goes to Tabriz. An ancient site on the Tiflis to Tabriz and Teheran road, the town had much transit trade, especially in salt, between Persia and the north in pre-railway days. Armenian tradition claims Noah as its founder, and a mound of earth as his grave. Ptolemy mentions it as Naxuana. The Persians sacked the town in the 4th century and it did not revive until the 10th century. Alp Arslan, Sultan of the Seljuk Turks, captured it in 1064 and the Mongols raided it in the 13th century. From this period onwards it was a bone of contention between Persians, Armenians and Turks. By the peace of Turkman-chai in 1828 it became Russian. The present houses have for the most part been quarried from ancient ruins. A gateway with a Persian inscription and the 12th century Tower of the Khans remain.

NAKHICHEVAN-ON-THE-DON, a town of Russia in the North Caucasian Area on the right bank of the Don, in 47° 18' N., 39° 45' E., 6 m. N.E. of Rostov-on-Don. Pop. (1926) 71,321. It shares in the trading prosperity of the latter town, and has smelting, rope and cloth works. It was founded in 1780 by Armenian immigrants, and their descendants still form a large percentage of the population along the banks of the Don.

NAKSKOV, a seaport of Denmark, in the amt (county) of Maribo, on a wide bay of the Laalands belt at the west end of the island of Laaland, 31 m. by rail W. of Nykjøbing. Pop. (1925), 13,817. A great dike, extending south-east to Rødby (20 m.), protects the coast against inundation. Naskov possesses a fine harbour and shipyards, and one of the largest sugar factories in Europe.

NAMAQUALAND, a region of south-western Africa, extending along the west coast over 600 m. from Damaraland (22° 43' S.) on the north to 31° S., and stretching inland 80 to 350 miles. It is divided by the lower course of the Orange river into two portions—Little Namaqualand to the south and Great Namaqualand to the north. Little Namaqualand forms part of Cape Colony (q.v.), and Great Namaqualand is the southern portion of German South-West Africa (q.v.). The people of Namaqualand are the purest surviving type of Hottentots, and number some twenty to thirty thousand.

NAMASUDRA, "low Shudra," the largest caste in Eastern Bengal, India; the older Chandal now divided into several sub-castes. *En masse* it ranks low, but its agricultural sub-castes stand higher. Numbering 2,172,823 in 1921, it shows no tendency to decline.

NAME. The distinguishing appellation by which a person, place, thing or class of persons or things is known. (O.Eng. *nama*; the word is common to all Indo-European languages.)

(a). **Savage and Barbarian**.—To the savage, and in a lessening but still considerable degree, to the barbarian and the civilized man in his earlier stages, the name shares the essence of the personality. Therefore a savage has a personal name which is seldom or never pronounced, he being referred to in common parlance by some nick-name or by a term of relationship. Not infrequently, to avoid calling the attention of evil spirits to him a savage child is not named at all, being referred to simply as "the child," or he may be given some derogatory name, as "grub," "filth," to deceive hostile powers. Apart from this, we may often distinguish, firstly a birth-name. This is given by the

parents or by some relation, as a rule, and its choice is governed by various considerations. Thus, he may be named from some trifling incident at the time of birth, or from the state of affairs in the country at the time ("Famine" and "War" are known Basuto names); or he may be given a name signifying "child of such a one" (patronymic or matronymic); or frequently among peoples who believe in reincarnation, he may be named after some dead relative supposed to be reborn in him. Very often, at puberty, or on undergoing some ceremony of initiation, he is given a new name, which may be kept secret. Various ceremonies often attend the giving even of the childhood-name.

(b). **Civilized.**—Modern surnames include: those derived from a place-name, as Johnston (the *ton* or steading of John); these often occur among noble families, as Dumaesque (*de Mariscis*, "of the marshes"; a plebeian equivalent is Marsh); from an occupation, as Smith, Miller; nicknames, as Longfellow, Campbell ("crooked-lip"); and patronymics, as Dickenson (son of Dicken). The familiar Celtic names of the types Ap Rhys, Bowen (Ap Owain), O'Brian, MacFarlane, are of this kind, the surname proper being of later development among Celts than among Teutonic peoples.

Roman Names.—The earliest Italian and Roman names, consisted of a personal name (*praenomen*), as Marcus, followed by an adjective signifying the clan to which the person belonged (*nomen*), as Caecilius, "of the gens *Caecilia*." All the *praenomina* had originally a meaning, as Gaius, "joyful." It is stated by the author of the little work *de praenominibus* that boys were never given a *praenomen* till they came of age, girls until they married. The latter statement is certainly wrong, since a woman never officially had a *praenomen* at all; the former is contradicted by most of the available evidence. It is possible, however, that a boy's name was not officially given him until he took the *toga virilis* or garb of manhood. Later, a third name was added, originally a personal name or nick-name, as *Pulcher*, "handsome." This was called a *cognomen*, and often became a family name, i.e., one common to all the direct descendants of its original bearer, who formed a section of the clan or *gens*. A man might have any number of these *cognomina*, as Publius Cornelius Scipio Aemilianus Africanus, where Scipio is the *cognomen* of the family into which the bearer had been adopted, Aemilianus an adjective formed from the name of his original clan, the *gens Aemilia*—this was a common, although not invariable, method of indicating adoption—and Africanus an officially bestowed title. (See also PLACE-NAMES.)

Law.—The Christian name, i.e., the name given to a person on admission to baptism into the Christian Church, dates back to the early history of the Church. In England individuals were for long distinguished by Christian names only, and the surname (see below) or family name is still totally ignored by the Church. In process of time the use of surnames became universal, the only exceptions in England being the members of the royal family, who sign by their baptismal names only.

A clergyman of the Church of England is compelled to perform the ceremony of baptism when required by a parishioner, and to give whatever name or names the godparents select, but although the rubrics do not expressly say so he can object to any name on religious or moral grounds.

The freedom enjoyed in England and the United States as to the kind of Christian name which may be given to a child is somewhat limited in France and Germany. In France, by a decree of the 11 Germinal, an XI., the only names permitted to be recorded in the civil register as Christian names (*prénoms*) of children were those of saints in the calendar and the names of personages known in ancient history. Even at the present day an official list is issued (revised from time to time) containing a selection of forenames, and no name of a child will be registered unless it occurs in this list. A limitation more or less similar prevails in Germany and other European countries.

As regards the surname, custom has universally decreed that a man shall be known by the name of his father. But in England and in some of the United States this custom is not legally binding; there is no law preventing a man from taking whatever name

he has a fancy for, nor are there any particular formalities required to be observed on the occasion of the adoption of a fresh surname. If a person adopts a new name and wishes to have it publicly notified and recognized in official circles, the method of procedure usually adopted is that by royal licence, which is subject to duty. If granted, the royal licence is given under the sign manual and privy seal of the sovereign, countersigned by the home secretary. Where there is a more formal adoption of a surname it is usual, for purposes of publicity and evidence, to advertise the change of name in the newspapers and to execute a deed poll setting out the change, and enrol the same in the central office of the supreme court. In America statutes in many States prescribe an application to a court of record as the method by which a person may change his name. A record of the change is thus certain to be made, but these statutes do not commonly deny an individual his common law right to change his name without resort to the courts.

Both in France and Germany official authorization must be obtained for any change of name. By the German Code 1900 (s. 12) if the right to a new name is disputed by another or his interest is injured thereby, the person entitled can compel the abandonment of the new name.

In England and the United States, a wife on marriage adopts the surname of her husband, disregarding entirely her maiden surname; in Scotland the practice usually is for the wife to retain her maiden surname for all legal purposes, adding the name of her husband as an alias. On remarriage the rule is for the wife to adopt the name of the new husband, but an exception to this is made in the case of a title acquired by marriage when the holder remarries a commoner. See in *Cowley v. Cowley*, 1901, A.C. 456.

In Spain and in her colonies a man takes the surname of his father, followed by the maiden surname of his mother, joined by "and" (*y*), but this conjunction is often omitted in some colonies.

Peers of Great Britain when signing their names use only their surnames or peerage designations. It is merely a privileged custom, which does not go back further than the Stuart period. Peeresses sign by their Christian names or initials followed by their peerage designation. Bishops sign by their initials followed by the name of the see. In Scotland it is very usual for landowners to affix to their names the designation of their lands, and this was expressly sanctioned by an act of 1672.

See *Ency. Eng. Law*, tits. "Christian Name," "Surname"; W. P. W. Phillimore, *Law and Practice of Change of Name* (1905); A. C. Fox-Davies and P. W. P. Carlyon Britton, *Law concerning Names and Changes of Name* (1906).

NAMPA, a city of Canyon county, Idaho, U.S.A., in the south-western part of the State, at an altitude of 2,492 ft., near the Snake river and 18 m. W. of Boise. It is on the Old Oregon Trail and the Oregon Short Line of the Union Pacific railway system. Pop. (1920) was 7,621—93% native white; 1928 local estimate over 11,000. Nampa is in the heart of an extensive and highly productive irrigated region, surrounded by grazing and timber lands, which in 1926 shipped 45,000 carloads (valued at \$75,000,000) of apples, vegetables (including 1,088 cars of the enormous Idaho potatoes), certified seeds, honey, wool, hides, sheep, cattle, lumber and other produce of the fields, forests and hills. It is a division point on the Union Pacific and an icing station for fruit cars. The icing plant has a manufacturing capacity of 150 tons a day, and a "dock" from which 110 cars can be re-iced in 20 minutes. Among the other industrial establishments are meat, poultry, and fruit packing plants, creameries and condenseries, a chick hatchery, grain elevators, a pickle factory, flour mills, wood-working plants and factories making boxes, brooms and apiary supplies. Electric-power is available from plants on the Snake river. The State sanatorium for the feeble-minded is located here.

NAMUR, one of the nine provinces of Belgium, between Hainaut on one side and Liège and Luxembourg on the other, extends from Brabant up the Meuse to the French frontier. Area, 1,414 sq.m.; pop. (1925) 353,363 or 250 per sq.m. It is fertile north of the Meuse and forested in the south. There are a few iron and coal-mines between the Sambre and Meuse, and the quarries are

important. Arboriculture, especially fruit-tree plantation, is increasing. There are three arrondissements, Namur, Dinant and Philippeville, fifteen cantons and 366 communes.

NAMUR (Flemish, *Namen*), a town of Belgium, capital of the province of Namur. Pop. (1925) 31,164. The town lies on the left bank at the junction of the rivers Sambre and Meuse, while the rocky promontory forming the fork between them is crowned with the old citadel, which occupies the site of the old castle of the counts of Namur. This citadel is no longer used for military purposes, and its hill is converted into a park, while the crest is occupied by a hotel reached by a cogwheel railway. Namur is connected with the citadel by two bridges across the Sambre, and from the east side of the promontory there is a fine stone bridge to the suburb of Jambes. This bridge was constructed in the 11th century and rebuilt in the reign of Charles V. It is the only old bridge in existence over the Belgian Meuse. The cathedral of St. Aubain or Albin was built in the middle of the 18th century. The church of St. Loup is a century older, and is noticeable for its columns of red marble from the quarry at St. Rémy near Rochefort. There is a considerable local industry in cutlery, and there are tanneries and glassmaking factories.

In the feudal period Namur formed a marquiseate in the Courtenay family. Jousts on stilts were a mediaeval custom that lasted into recent times here. Don John of Austria made Namur his headquarters in the Netherlands, and died here in 1578. Louis XIV. took it in 1692 and Vauban renewed the defences but William III. retook it in 1695, though the French held it again from 1702-12. In 1893, under the new scheme of Belgian defence, the citadel and its detached works were abandoned, and in their place nine outlying forts were constructed at a distance of from 3 to 5 m. Namur suffered considerably in the World war. (See BELGIUM, INVASION OF.)

NANAIMO, a city of British Columbia, on the east coast of Vancouver island. Pop. (with suburbs) (1921), 9,088. It is connected with Victoria by the Esquimalt and Nanaimo railway, and has a daily steamer service to Vancouver. It is in a fruit-farming, dairying and poultry raising district, and has a good harbour, carrying on a large trade in coal from the neighbouring mines, and in cured herrings, which are sent to the east. The industries include sawmills and wood-working shops, breweries, canneries, foundries, brickworks, etc.

NANA SAHIB, the common designation of Dandu Panth, an adopted son of the ex-peshwa of the Mahrattas, Baji Rao, who took a leading part in the great Indian Mutiny (q.v.) and was proclaimed peshwa by the mutineers. Nana Sahib had a grievance against the British Government because they refused to continue to him the pension of eight lakhs of rupees (£80,000) which was promised to Baji Rao by Sir John Malcolm on his surrender in 1818. This pension, however, was only intended to be a life grant to Baji Rao himself. For this refusal the Nana bore the British a lifelong grudge, which he washed out in the blood of women and children in the massacres at Cawnpore (q.v.). In 1859, when the remnants of the rebels disappeared into Nepal, the Nana was among the fugitives. His death was reported some time afterwards, but his real fate remains obscure.

NAN-CHANG, the capital of the province of Kiangsi, China, situated on the Kankiang, up which boats may come from Poyang lake. The population has been variously estimated at 300,000-500,000, and there is considerable commerce, chiefly in the agricultural products of the province, which include tea, rice, cotton, tobacco, hemp, etc. Some of the more northerly cereals are also grown and dealt in. Some manufactures are carried on.

NANCY, a town of north-eastern France, the capital formerly of the province of Lorraine, and now of the department of Meurthe-et-Moselle, 219 m. E. of Paris on the railway to Strasbourg. Pop. (1926) 108,439.

At the close of the 11th century Odelric of Nancy, brother of Gerard of Alsace, possessed at Nancy a castle which enabled him to defy the united assaults of the bishops of Metz and Treves and the count of Bar. In the 12th century the town was surrounded with walls, and became the capital of the dukes of Lorraine; and in 1477 Charles the Bold was defeated here by René

II. (See SWISS WARS.) Refortified by Charles III., it was taken by the French in 1633. After the peace of Ryswick in 1697 it was restored to Duke Leopold. He founded academies, established manufactures and set about the construction of the new town. But it was reserved for Stanislas Leczinski, the last of the dukes of Lorraine, to make Nancy one of the palatial cities of Europe. The city, which became French in 1766, was occupied by the allies in 1814 and 1815, and put to ransom by the Prussians in 1870. After the Franco-German war the population was greatly increased by the immigration of Alsatians and of people from Metz and its district.

Although Nancy remained outside the area of actual fighting during the World War it was bombarded by German aeroplanes and long-range guns, but the damage was not very serious.

Nancy stands on the left bank of the Meurthe 6 m. above its junction with the Moselle and on the Marne-Rhine canal. The railway from Paris to Strasbourg skirts the city on the south-west side; other railways—to Metz, to Épinal by Mirecourt, to Château Salins—join the main line near Nancy, and make it an important junction. The town consists of two portions—the *Ville-Vieille* in the north-west, with narrow and winding streets, and the *Ville-Neuve* (16th-18th centuries) in the south-east with wide straight streets. Between the two lies the Place Stanislas, and on all sides rise imposing buildings of the 18th century—the town hall, episcopal palace, etc. A fine triumphal arch erected by Stanislas in honour of Louis XV. leads from the Place Stanislas to the Place Carrière, which forms a beautiful tree-planted promenade, containing at its further end the government palace (1760) now the residence of the general commanding the XX. army corps, and adjoins the so-called Pépinière (nursery) established by Stanislas.

The cathedral in the Ville-Neuve, built in the 18th century, has a wide façade flanked by two dome-surmounted towers. Of particular interest is the church of the Cordeliers, in the old town, built by René II. about 1482 to commemorate his victory over Charles the Bold. Pillaged during the Revolution period, but restored to religious uses in 1825, it contains the tombs of the counts of Vaudémont. Here also is a chapel built at the beginning of the 17th century to receive the tombs of the princes of the house of Lorraine. The church of St. Epvre, rebuilt between 1864 and 1874 on the site of an old church of the 13th, 14th and 15th centuries, has a fine spire and belfry and good stained glass windows. Of the old ducal palace, begun in the 15th century by Duke Raoul and completed by René II., there remains but a single wing, partly rebuilt after a fire in 1871. The entrance to this wing, which contains the archaeological museum of Lorraine, is Gothic of the early 16th century. One of the greatest treasures of the collection is the tapestry found in the tent of Charles the Bold after the battle of Nancy. Of the old gates of Nancy the most ancient and remarkable is the Porte de la Crafte (1463). The town hall contains a museum of painting and sculpture.

Nancy is the seat of a bishop, a prefect, a court of appeal and a court of assizes, headquarters of the XX. army corps, and centre of an *académie* (educational division) with a university comprising faculties of law, medicine, science and letters, and a higher school of pharmacy. There are also tribunals of first instance and of commerce, a board of trade-arbitrators, and a national school of forestry. The industries of Nancy include printing, brewing, cotton- and wool-spinning and the weaving of cotton and woollen goods, and the manufacture of tobacco (by the State), of boots and shoes, straw hats, pottery, casks, embroidery, machinery, motor cars and spare parts, engineering material, farm implements and iron goods.

NANDI, an East African tribe of mixed Nilotic, Bantu and Hamitic origin. With them are more or less closely allied the Lumbwa (correctly Kipsikis), Buret (or Puret) and Sotik (Soot) tribes, as well as the Elgonyi (properly Kony) of Mount Elgon. They have also affinities with the Masai. The Nandi-Lumbwa peoples inhabit the country stretching south from Mount Elgon to about 1° S. and bounded east by the escarpment of the eastern rift-valley and west by the territory of the tribes, such as the

Kavirondo, dwelling round the Victoria Nyanza. They have given their name to the Nandi plateau. They have a double administrative system, the chief medicine man or *Orkoivot* being supreme chief and regulating war affairs, while representatives of the people, called *Kiruogik*, manage the ordinary affairs of the tribe.

The medicine men are of Masai origin and the office is hereditary. The young men form a separate warrior class to whom is entrusted the care of the country. A period of about $7\frac{1}{2}$ years is spent in this class, and the ceremony of handing over the country from one "age" to the succeeding "age" is of great importance. (See AGE GRADES.) The arms of the warriors are a stabbing spear, shield, sword and club. Many also possess rifles. All the Nandi are divided into clans, each having its sacred animal or totem. They have no towns, each family living on the land it cultivates. The huts are of circular pattern. The Nandi believe in a supreme deity—Asis—who takes a benevolent interest in their welfare, and to whom prayers are addressed daily. Their language is Nilotic. The primitive hunting tribe known as the Wandorobo speak a dialect closely resembling Nandi.

See A. C. Hollis, *The Nandi: Their Language and Folk-lore*, with introduction by Sir Charles Eliot (1909), and the works there cited.

BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY
LUMBWA WARRIOR
EQUIPPED TO SPEAR LIONS

NANDU, the Brazilian name for the rhea (*q.v.*).

NANKANA, a people resembling the Bura and the Mam-pursi, living in the Navoro district of the Northern Territories, Gold Coast, and across the Upper Volta border in the Leo district. They speak a Mossi dialect.

See Cardinal, *The Natives of the Gold Coast*.

NANKEEN, a cotton cloth originally made in China, and now imitated in various countries. The name is derived from Nanking, the city in which the cloth is said to have been originally manufactured. The characteristic yellowish colour of nankeen is attributed to the peculiar colour of the cotton from which it was originally made.

NANKING ("the southern capital"), the name by which Kiang-ning, the chief city in the province of Kiangsu, China, has been known for several centuries. Pop. about 390,000. The city is nearly equidistant between Canton and Peking, on the south bank of the Yangtze Kiang 235 m. from the sea. It dates only from the beginning of the Ming dynasty (1368), although it is built on the site of a city which for more than two thousand years figured under various names in the history of the empire. The more ancient city was originally known as Kin-ling; under the Han dynasty (206 B.C. to A.D. 25) its name was converted into Tan-yang; by the T'ang emperors (A.D. 618-907) it was styled Kiang-nan and Shêng Chow; by the first sovereign of the Ming dynasty (A.D. 1368-1644) it was created the "southern capital" (Nan-king), and was given the distinctive name of Ying-t'ien; and with the accession to power of the Manchu rulers it was officially known as Kiang-ning, though still popularly called Nan-king. It was the seat of the imperial court only during the reigns of the first two emperors of the Ming dynasty, and was deserted for Shun-t'ien (Peking) by Yung-lo, the third sovereign of that line, who in 1403 captured the town and usurped the crown of his nephew, the reigning emperor.

The T'ai'ping rebels, who carried the town by assault in 1853, swept away all the national monuments and most of the public buildings it contained, and destroyed the greater part of the magnificent wall which surrounded it. The wall, of which only small portions remain, was about 70 ft. in height, measured 30 ft. in thickness at the base, and was probably 20 miles in circumference and pierced by thirteen gates. Encircling the north, east and south sides of the city proper was a second wall which enclosed about double the space of the inner enclosure. In the north-

east corner of the town stood the imperial palace reared by Hung-wu, the imperial founder of the modern city. After suffering mutilation at the overthrow of the Ming dynasty, this building was burnt to the ground on the recapture of the city from the T'ai'ping rebels in 1864. The most conspicuous public building at Nanking was the famous porcelain tower, which was designed by the emperor Yung-lo (1403-1428) on a previously sacred site to commemorate the virtues of his mother. The building was begun in 1413. In shape the pagoda was an octagon, and was about 260 ft. in height. The outer walls were cased with bricks of the finest white porcelain, and each of the nine stories into which the building was divided was marked by overhanging eaves composed of green glazed tiles of the same material. Hung on chains which stretched from this apex to the eaves of the roof were five large pearls of good augury for the city's safety from flood, fire, storm and civil disturbance.

Nanking was formerly one of the chief literary centres of the empire. It was taken by the British in 1842 and made a treaty port by the French treaty of 1858, but was not formally opened. Its proximity to Chinkiang, where trade had established itself while Nanking was still in the hands of the rebels, made its opening of little advantage. In 1899 it was voluntarily thrown open to foreign trade by the Chinese government, and in 1909 it was connected by railway with Shanghai. Satin, crêpe, nankeen, cloth, paper, pottery and artificial flowers were among its chief manufactures. There is a depth of from 17 to 45 ft. at the quays and all vessels can reach Nanking if they are able to pass the flats at the mouth of the Yangtze. The town imports cotton goods and yarn, metals, bean and kerosene oil and sugar. The exports include silk goods, skins, beans and frozen meats and dairy produce.

The Nationalist Government (Kus Min Tang) decided to remove the capital from Peking as a further dissociation from the old régime, and, in view of the special position of Nanking, this city was chosen as the republican capital. In 1928 and 1929, Nanking was the scene of frequent disorder, connected with the alleged malpractices of the Nationalist authorities but its position as the headquarters of the republican authorities offers too many advantages for it lightly to be given up.

NANNING, a treaty port in the province of Kwangsi, south China (22° 48' N., and 108° 15' E.), and recently created capital of the province, is situated about 30 miles below the junction of the two branches (Tso-kiang and Yu-kiang) of the south (main) stream of the West River, and about 470 miles above Canton. Nanning was voluntarily opened to foreign trade by China in 1907 to offset French influence at Lungchow, a Treaty port near the Tongking frontier. It is the highest accessible point for steamers on the West River, but the river between Wuchow and Nanning during winter suffers from lack of water so that trade is seriously affected. Numerous small competitive river vessels run between Wuchow and Nanning. Its economic orientation is towards the Canton delta by the natural route of the Si-kiang, rather than towards the nearer Red River delta of Tongking. The construction, however, of the projected railway from Canton, via Nanning, to connect with the Tongking railway system at Langson (the present terminus) may have the effect of diverting some of the trade of Nanning into Tongking; or again, the construction of a railway may draw much of it to Pakhoi on the Gulf of Tongking, the nearest outlet by sea to Nanning.

The value of the whole trade in 1924 was as follows:—net foreign imports 2,758,547, net Chinese imports 1,824,497, exports 2,040,392; total 6,623,437 Hk Taels. The trade of the port in 1926 suffered as a result of the Hongkong boycott. The chief imports of Nanning, to be distributed in W. Kwangsi, and adjacent Yunnan and Tongking, are cotton piece goods, kerosene, clothing, matches, straw mats, while exports comprise chiefly aniseed, beans, hides, groundnut cake, medicines, and antimony (the export of which increased greatly during the World War). Nanning is a collecting and distributing centre for a considerable area further west. Two main channels serve this trade—the Yu-kiang which is navigable for large junks during the summer flood season as far as Pose-ting (whence a road leads up to the

high plateau of Yünnan), and the Tso-kiang which is navigable for large junks and small launches as far as the Treaty port of Lungchow, close to the Tongking border.

The population of the port of Nanning as returned for 1926 by the Chinese Maritime Customs is 65,800.

NANNY-BERRY (*Viburnum Lentago*), a handsome North American shrub or small tree of the honeysuckle family (Caprifoliaceae), called also black haw, sheep-berry, wild raisin and sweet viburnum, sometimes planted for ornament. It is native to rich soil from Quebec to Hudson bay and southward to New Jersey, Georgia and Colorado. The nanny-berry, though usually a shrub, sometimes grows 30 ft. high, with a trunk diameter of 10 inches. It has slender branches, ovate, long-pointed, finely-toothed leaves and bears small white flowers borne in showy clusters, 2 to 5 in. broad. The oval, bluish-black, sweet, edible fruit ripens in late autumn.

NANSEN, FRIDTJOF (1861–), Norwegian scientist, explorer and statesman, was born at Frøen near Christiania, where he spent his childhood, on Oct. 10, 1861. In his fifteenth year his parents removed to Christiania, where he went to school. He entered Christiania university in 1880 and studied zoology; in March 1882 he joined the sealing-ship "Viking" for a voyage to Greenland waters. On his return he became curator of the Bergen Museum, under Daniel Cornelius Danielssen (1815–1894). In 1886 he spent a short time at the zoological station at Naples, during which he wrote papers and memoirs on zoological and histological subjects, for one of which, "The Structure and Combination of the Histological Elements of the Central Nervous System" (Bergen, 1887), the Christiania university conferred upon him the degree of doctor of philosophy. But his voyage in the "Viking" had indicated Greenland as a possible field for exploration, and in 1887 he began preparations for a crossing of the great ice-field of the interior of that country. Nansen took with him Otto Sverdrup (b. 1855), Captain O. C. Dietrichson (b. 1856), K. K. Trana (b. c. 1864), and two Lapps. The expedition started in May 1888, proceeded from Leith to Iceland, and there joined a sealing-ship bound for the east coast of Greenland. On Aug. 16 began the ascent of the inland ice amid storms, intense cold, and other hardships, they reached the highest point of the journey (8,920 ft.) on Sept. 5, and on the 28th struck the west coast at Ameralik Fjord. They were obliged to winter at the settlement of Godthaab, and Nansen used the opportunity to study the Eskimos and gather material for his book *Eskimo Life* (English translation, London, 1893). The party returned home in May 1889. A report of the scientific results was published in *Petermanns Mittheilungen* (Gotha, 1892). On his return from Greenland Nansen became curator of the Zoötomie Museum of Christiania university. In Sept. 1889 he married Eva, daughter of Professor Michael Sars of Christiania university, and a noted singer (d. 1907).

In 1890 he propounded his scheme for a polar expedition before the Norwegian Geographical Society, and in 1892 he laid it before the Royal Geographical Society in London. (See "How can the North Polar Region be crossed?" *Geogr. Journal*, vol. i.) His adversely criticized plan succeeded. The Norwegian parliament granted two-thirds of the expenses, and the rest was obtained by subscription from King Oscar and private individuals. His ship, the "Fram" (i.e., "Forward"), was specially built of immense strength and peculiar form, being pointed at bow and stern and having sloping sides, so that the colliding ice-floes would tend, not to crush, but merely to slip beneath and lift her. She sailed from Christiania on June 24, 1893. Otto Sverdrup was master; Sigurd Hansen, a Norwegian naval lieutenant, was in charge of the astronomical and meteorological observations; Henrik Blessing was doctor and botanist. On Sept. 22 the "Fram" was made fast to a floe in 78° 50' N., 133° 37' E.; she was frozen in, and the long drift began. She bore the pressure of the ice perfectly. On March 14, 1895, Nansen, being satisfied that the "Fram" would continue to drift safely, left her in 84° N., 101° 55' E., and started northward on foot with Johansen. On April 8 they turned back from 86° 14' N., the highest latitude then reached by man; and they shaped their course for Franz Josef Land. They suffered

from shortage of food, and were compelled to winter on Frederick Jackson Island (so named by Nansen) in Franz Josef Land from Aug. 26, 1895, to May 19, 1896. They were uncertain as to the locality, but, after having reached 80° N. on the south coast of the islands, they were travelling westward to reach Spitsbergen, when, on June 17, they fell in with Frederick Jackson and his party of the Jackson-Harmsworth expedition, and returned to Norway in his ship, the "Windward," reaching Vardö on Aug. 13. A week later the "Fram" also reached Norway safely, having drifted north to 85° 57', and returned by the west coast of Spitsbergen. A great welcome awaited Nansen. In England he gave the narrative of his journey at a great meeting in the Albert Hall, London (Feb. 8, 1897), and elsewhere.

In 1896 a professorship of zoology was established for him at the Christiania university; he worked up the results of his expedition and made scientific research in physical geography and oceanography. In the summer of 1900 he took part in an Arctic oceanographic expedition in the S.S. "Michael Sars," headed by Dr. Johan Hjort, and became director of the International Central Laboratory in Christiania for the Research of the Sea. In 1902 he published *The Oceanography of the North Polar Basin*, and in 1904 *The Bathymetrical Features of the North Polar Seas*. In 1905 Nansen took up politics, issuing a manifesto and many articles in connection with the crisis between Norway and Sweden. His attitude may be summarized by the last words of a short work published later in the year: "Any union in which the one people is restrained in exercising its freedom is and will remain a danger" (*Norway and the Union with Sweden*, London, 1905). On the establishment of the Norwegian monarchy Nansen was appointed minister to England (1906), and in the same year was created G.C.V.O. In 1908 he retired from his post and returned to his scientific work as professor of oceanography at Christiania university. In co-operation with Professor Bjorn Helland-Hansen, of the Bergen Museum, he wrote *The Norwegian Sea, its Physical Oceanography* (Report on Norwegian Fishery and Marine Investigations, vol. 2, 1909).

In 1910 Nansen made an oceanographic cruise in the "Fritthof" through the northeastern North Atlantic from Ireland to Iceland and back to Norway, and in 1911 published *In Northern Mists* (2 vol.) on the exploration of the northern regions from early times up to the beginning of the 16th century. In 1912 he made a further oceanographic cruise to Spitsbergen and the waters to the north in his yacht the "Veslemøy," and in 1913 he made an expedition through the Arctic and the Kama Seas to the mouth of the Yenisei river and through Siberia and the Amur region.

In 1914, jointly with Helland-Hansen, Nansen made an oceanographic expedition in the eastern North Atlantic to Portugal, Madeira and the Azores and back to Norway. During the World War oceanographic expeditions were impossible. In 1917 Nansen became head of a Norwegian Govt. commission to the United States, and secured a satisfactory agreement with the American Govt. in regard to the import into Norway of essential supplies. After the Armistice (1918) Nansen, as Commissioner of the League of Nations with the executive assistance of the national Red Crosses, was responsible for the repatriation of about 500,000 prisoners of war from Siberia, China and other parts of the world. This work was financed largely by the governments participating in the International Committee for Relief Credits, Paris, of which Lord Bradbury was chairman.

In 1919 Nansen conferred with Hoover on the possibilities of assisting the Russian people, and suggested an organization on the lines of the Belgian Relief Commission. The Supreme Council supported the proposal on the condition that all hostilities in Russia cease. As this was at the time when Kolchak and Denikin were advancing towards Moscow the project was abandoned. In 1921 Nansen was asked by an international conference in Geneva of delegates of 48 Red Cross societies and 12 governments to direct relief work for famine-stricken Russia, and on Aug. 27 he signed an agreement in Moscow with Chicherin, the Soviet Foreign Minister, regarding the method of furnishing relief on a large scale, and visited the famine areas. In Sept. Nansen failed to induce the League of Nations to assist the starving

millions in Russia by raising, under safeguards, an international governmental relief loan. He next visited the chief capitals of Europe, and as a result the European Red Crosses fed and clothed at the peak of the Russian famine over 1,600,000 inhabitants of the Volga and South Ukraine regions. His publicity campaign had great influence in America, which under Hoover's direction fed at one time 10,000,000 Russian sufferers. Nansen's mission in Russia continued to conduct two agricultural demonstration estates in the former famine areas. In 1923 Nansen published *Russia and the Peace* setting out the economic position of Soviet Russia. As high commissioner for refugees to the League, he was responsible for the protection and settlement of Russian, Armenian and Greek refugees.

In 1923 Nansen was awarded the Nobel Peace Prize, which he gave to the furtherance of the Nansen agricultural demonstration estates and model farms in Saratov and Ekaterinoslav Governments, Russia. In his early manhood Nansen was a great athlete and the popularity of ski-ing in the Alps is largely due to him; and evidence of his enthusiasm for sport is his work on *Sport in the Polar Regions and Wild Norway* (1925). Nansen, as delegate for Norway to the League of Nations, made an impassioned intervention protesting against the occupation of Corfu by Italy in 1923, and at the Fifth Assembly in 1924 he conducted the first informal negotiations for the entry of Germany into the League of Nations. Nansen's interest in education has been evidenced by his campaign in favour of Russian professors and universities. In 1925 he was elected lord rector of St. Andrews, and in 1928 published *Armenia and the Near East*. (See POLAR REGIONS; REFUGEES.)

Besides works mentioned above, Nansen described his travels in *The First Crossing of Greenland* (Eng. trans., 1893); *Farthest North* (Eng. trans., 1897); *The Waters of the Northeastern North Atlantic* (*Internationale Revue der gesammten Hydrobiologie und Hydrogeographie*, Leipzig, 1913); *En ferd til Spitzbergen* (1912); *Through Siberia, the Land of the Future* (London, 1914). The scientific results of the various expeditions are given in the following works—the 1888 expedition, in *Petermanns Mitteilungen* (Gotha, 1892); the 1893 expedition, in *The Norwegian North Polar Expedition, 1893-96: Scientific Results* (London, etc., 1900 sqq.); the 1912 expedition, in *Spitzbergen Waters* (Society of Science, Oslo, 1915); of the 1914 expedition jointly with Helland-Hansen, in *The Eastern North Atlantic* (Geophysic Publication, Academy of Science, Oslo).

NANTERRE, a suburb 13 kilometres north-west of Notre Dame de Paris, with a port on the Seine, in the department of Seine, at the foot of Mount Valerien, 8 m. N.W. of Paris on the railway to St. Germain. Pop. (1926) 31,038. The principal manufactures are chemicals, tallow and aluminium; stone is quarried in the vicinity; the town is noted also for its cakes. Nanterre (the ancient *Nemtodurum* or *Nemetodurum*) owes its origin to the shrine of Ste. Geneviève (420-512), the patron-saint of Paris. The shrine is the object of a pilgrimage in September.

NANTES, a city of western France, capital of the department of Loire-Inférieure, on the Loire, 35 m. above its mouth, at the junction of the Orléans, Ouest-état and State railways, 55 m. W.S.W. of Angers by rail. In population (1926, 166,507), Nantes is the first city of Brittany. The Loire here divides into several branches forming islands over portions of which the city has spread.

History.—Before the Roman occupation Nantes was the chief town of the Namnetes and consisted of *Condivicnum*, lying on the hills away from the river, and of *Portus Namnetum*, on the river. Under the Romans it became a great commercial and administrative centre, though its two parts did not coalesce till the 3rd or 4th century. In the middle of the 3rd century Christianity was introduced by St. Clair. Clotaire I. got possession of the city in 560, and placed it under the government of St. Félix the bishop, who caused the Loire to flow under the walls of the castle. After being several times subdued by Charlemagne, Brittany revolted under his successors, and Nominoë, proclaimed king in 842, razed the fortifications of Nantes because it had sided with Charles the Bald. The Normans held the town from 843 to 936. About this time began the rivalry between Nantes and Rennes, whose counts disputed the sovereignty of Brittany. Pierre de Dreux, declared duke of Brittany by Philip Augustus, made Nantes his capital,

surrounded it with fortifications and defended it against John of England. During the Breton wars of succession Nantes took part first with Jean de Montfort, but afterwards with Charles of Blois, and did not open its gates to Montfort till his success was assured and his English allies had retired. In 1560 Francis II. granted Nantes a communal constitution. Averse to Protestantism, it joined the League along with the duke of Mercœur, governor of Brittany, who helped to raise the country into an independent duchy; and it was not till 1598 that it opened its gates to Henry IV., who here signed on May 2 of that year the famous Edict of Nantes which until its revocation by Louis XIV. in 1685 was the charter of Huguenot liberties in France. The city was in 1793 the scene of the *noyades* of J. B. Carrier, envoy of the Committee of Public Safety.

The Port.—The maritime port of Nantes is reached by way of the Loire and the ship canal between the island of Carnet and La Martinière (9½ m.). Vessels drawing as much as 20 ft. 8 in., and at spring tides, 22 ft., can reach the port, which extends over a length of about 1½ m. The outer port stretches ½ m. to Chantenay. The principal quays extend along the right bank of the branch which flows past the town, and on the western shore of the island of Gloriette. Their total length used for trading purposes is 5 m., and warehouses cover an area of 17 ac. A slipway facilitates the repairing of ships. The river port occupies the St. Félix and Madeleine branches, and has quays extending for half a mile. Finally, on the Erdre is a third port for inland navigation. The quays are bounded by railway lines along the right bank of the river, which the railway to St. Nazaire follows. The older quarter of Nantes is situated to the east of the Erdre.

Buildings.—The cathedral, built above a 12th century crypt, was unfinished till the 19th century. There are two interesting monuments in the transept; Michel Colomb's tomb of Francis II., duke of Brittany, and his second wife Marguerite de Foix (1507), and that of Gen. Juchault de Lamoricière, a native of Nantes, by Paul Dubois (1879). Between the cathedral and the Loire stands the castle of Nantes, founded in the 9th or 10th century. Rebuilt by Francis II. and the duchess Anne, it is flanked by huge towers and by a bastion erected by Philip Emmanuel duke of Mercœur in the time of the League. A fine Gothic façade looks into the courtyard. From being the residence of the dukes of Brittany, the castle became a state prison and is now occupied as the artillery headquarters. The chapel in which the marriage of Louis XII. with Anne of Brittany was celebrated was destroyed in 1800. Nantes has an archaeological collection in the Dobrée museum, and in the museum of fine arts a splendid collection of paintings, modern French masters being well represented. It is the seat of a prefect, of a bishopric under the archbishop of Tours and a court of assizes, and headquarters of the XI. army corps; it has tribunals of first instance and of commerce, a board of trade-arbitrators and a chamber of commerce. It has many educational institutions.

Industries.—Among the more important industries of Nantes are sugar-refining, rice-husking, the manufacture of oil, soap, flour pastes and biscuits, chocolate and the preparation of tinned provisions (sardines, vegetables, etc.); the manufacture of tin boxes, tiles, chemical manures, acid, leather, paper, rope, boots and shoes, brushes, porcelain and glass; shipbuilding, metal founding and the construction of engineering material; and wool and cotton-spinning and the manufacture of cotton and other fabrics, rubber goods, hosiery and knitted goods. Coal and petroleum, sugar, coffee, cotton-seed, copra, hemp, grain, phosphates and pyrites, timber and pulp-wood are imported. The principal exports are machinery, pit-props, iron ore, slate, hoops and provisions. The merchandise handled at the port of Nantes has slightly increased since 1913 when the amount of goods handled at the port was 1,964,000 tons (metric). In 1924 it was 2,154,000 and in 1925, 2,086,000 metric tons.

NANTES, EDICT OF, the law promulgated in April 1598 by the French king, Henry IV., which secured a large measure of religious liberty to his Protestant subjects, the Huguenots. Its main provisions may be summarized as follows: (1) It gave liberty of conscience to the Protestants throughout the whole

of France. (2) It gave them the right of holding public worship in those places where they had held it in 1576 and the earlier part of 1577; also in places where this freedom had been granted by the edict of Poitiers (1577) and the treaties of Nérac (1579) and of Fleix (1580). The Protestants could also worship in two towns in each *bailliage* and *sénéchaussée*. The greater nobles could hold Protestant services in their houses; the lesser nobles could do the same, but only for gatherings of not more than 30 people. Regarding Paris, the Protestants could conduct worship within five leagues of the city instead of ten leagues as previously. (3) Full civil rights were granted them. They could trade freely, inherit property and enter the universities, colleges and schools. All official positions were open to them. (4) To deal with disputes arising out of the edict, a chamber was established in the parlement of Paris (*le chambre de l'édit*). This group was to be composed of ten Roman Catholic and six Protestant members. Chambers for the same purpose, but consisting of Protestants and Roman Catholics in equal numbers, were established in connexion with the provincial parlements. (5) The Protestant pastors were to be paid by the State and to be freed from certain burdens, their position being made practically equal to that of the Roman Catholic clergy. (6) A hundred places of safety were given to the Protestants for eight years, the expenses of garrisoning them being undertaken by the king.

The edict was greatly disliked by the Roman Catholic clergy, and a few changes were made to conciliate them. The parlement of Paris shared this dislike, but was forced by the king to register the edict on Feb. 25 1599. After similar trouble it was also registered by the provincial parlements, the last being the parlement of Rouen, which delayed the registration until 1609.

That the strong political position thus secured to the French Protestants was a danger to the State was proved by the troubles which arose during the minority of Louis XIII. After Richelieu had succeeded in crushing the quasi-independent power of the Huguenot lords and cities, however, the French Protestants ceased to be a political danger. With the revocation of the Edict of Nantes, on Oct. 18 1685, the French Protestants were deprived of all civil and religious liberty.

BIBLIOGRAPHY.—See FRANCE: *History*; and HUGUENOTS. For further details see the papers and documents published as *Le Troisième centenaire de l'édit de Nantes* (1898); N. A. F. Puaux, *Histoire du Protestantisme français* (Paris, 1894); H. M. Baird, *The Huguenots and the Revocation of the Edict of Nantes* (London, 1895); A. Lods, *L'Édit de Nantes devant le parlement de Paris* (1899); and C. Benoist, *La Condition des Protestants sous le régime de l'édit de Nantes et après sa révocation* (Paris, 1900).

NANTEUIL, ROBERT (1623–1678), French line-engraver, was born about 1623, or, as other authorities state, in 1630, the son of a merchant of Reims. Having received an excellent classical education, he studied engraving under his brother-in-law, Nicholas Regnesson. He became known by his crayon portraits, and was pensioned by Louis XIV. and appointed designer and engraver of the cabinet to that monarch. It was mainly due to his influence that the king granted the edict of 1660, dated from St. Jean de Luz, by which engraving was pronounced free and distinct from the mechanical arts, and its practitioners were declared entitled to the privileges of other artists. He died at Paris in 1678. The plates of Nanteuil, several of them almost life-size, number about three hundred. In his early practice he imitated the technique of his predecessors, working with straight lines, strengthened, but not crossed, in the shadows, in the style of Claude Mellan, and in other prints cross-hatching like Regnesson, or stippling in the manner of Jean Boulanger. He then gradually acquired an individual style, modelling the faces of his portraits with the utmost precision and completeness, and employing various methods of touch for the draperies and other parts of his plates. Among the finest of his mature works are the portraits of Pomponne de Bellièvre, Gilles Ménage, Jean Loret, the duc de la Meilleraye and the duchess de Nemours.

A list of his works will be found in Dumesnil's *Le Peintre-graveur français*, vol. iv.

NANTICOKE, a borough of Luzerne county, Pennsylvania, U.S.A., on the Susquehanna river and Federal highway 11, 8 m.

W.S.W. of Wilkes-Barre. It is served by the Pennsylvania railroad and (through West Nanticoke) by the Lackawanna, and for freight also by the Central of New Jersey. Pop. (1920) 22,614 (29% foreign-born white). It is an important anthracite-mining centre, and has a number of factories (making chiefly silk yarn, stockings and cigars) with an output in 1925 valued at \$2,630,227. Nanticoke was laid out in 1793 and was incorporated in 1874.

NANTUCKET, an island 28m. S. of Cape Cod off the south-east coast of Massachusetts, was for more than a century a principal seat of the whaling industry. In 1830 the town of Nantucket ranked after Boston and Salem as the third commercial city of the State; in 1842 it was the home port of 86 ships and barks, 2 brigs and 2 schooners, with a total capacity of 36,000 tons. Leadership in the industry had passed to New Bedford about 1820, however, and soon after 1840 the decline of whaling began in earnest. Retaining its old atmosphere and a distinctive physical character inherited from years of Quaker dominance and whaling prosperity, Nantucket has become a famous summer resort. Its population, once about 10,000, was 3,152 in 1925. For the most part the island is sandy and level. It has few trees and few hills, the highest of which is 191ft. above the sea. Although the length of the island proper is only about 15m. and its average width 2½m., there are 88m. of shore. The climate is profoundly modified by this insular position. Slightly separated from Nantucket are the smaller islands of Tuckernuck and Muskeget.

Nantucket was discovered by Bartholomew Gosnold and purchased, with Martha's Vineyard, by Thomas Mayhew of Watertown in 1641. Thomas Macy led the first band of settlers in 1659, founding a village at what is now Madaket. The present site of Nantucket town was occupied in 1672, named Sherburne in 1673 and rechristened Nantucket in 1695. Christopher Hussey took the first sperm whale in 1712, and development of the vessel fishery, succeeding the old shore fishery of whales, was rapid. The American Revolution, the War of 1812 and the American Civil War were the only interruptions to the prosperity based upon whaling until its final decline. Modern Nantucket is described as an "almost perfect record of what our Yankee forefathers considered a seemly town." The island has extensive fisheries.

Shaler, "Geology of Nantucket," *Bulletin No. 53, U.S. Geological Survey* (1889); *Bulletins Nantucket Historical Society* (1894, et seq.); R. A. D. Lithgow, *Nantucket, A History* (1914); W. F. Macy, *Story of Old Nantucket* (1915); W. F. Macy and R. B. Hussey, *Nantucket Scrap Basket* (1916); A. Starbuck, *History of Nantucket* (1924). (H. B. H.)

NANTWICH, a market town and urban district in the Crewe parliamentary division, Cheshire, England, 16½ m. N.W. of London, on the L.M.S. and G.W. railways. Pop. (1921) 7,296. It lies on the river Weaver, in the upper part of its flat, open valley. The church of St. Mary and St. Nicholas is a cruciform building in red sandstone, of the Decorated and Perpendicular periods, with a central octagonal tower. The fine old carved stalls are said to have belonged to Vale Royal abbey, near Winsford. Nantwich retains a few old timbered houses (16th and 17th centuries), but the town as a whole is modern in appearance. The grammar school was founded in 1611. The salt industry was so important here in the time of Henry VIII. that there were three hundred salt-works. Though this industry has lapsed here, there are now brine baths, and the former mansion of Shrewbridge Hall is converted into a hotel with a spa. Nantwich has tanneries, a manufacture of boots and shoes, and clothing factories; and corn-milling and iron-founding are carried on.

Remains found in the district indicate a Roman settlement here, probably because of the salt. The Domesday Survey contains a long account of the laws, customs and values of the salt-works. The salt-houses were divided between the king, the earl of Chester and certain resident freemen. The name of the town appears variously as Wych Manbank, Wie Malban, Nantwich, Lache Mauban, Wysmanban, Wiens Malbanus, Nampptewiche. About the year 1070 William Malbedeng was created baron of Nantwich, but the barony became subdivided later. The only town charter was granted by Queen Elizabeth (1568). There was a gild merchant and also a town bailiff, but the latter office was

soon dropped. There is documentary evidence of a castle at Nantwich in the 13th century.

NANTY-GLO, a coal-mining borough of Cambria county, Pennsylvania, U.S.A., 24 m. W.S.W. of Altoona; served by the Cambria and Indiana and the Pennsylvania railways. Pop. 5,028 in 1920 (27% foreign-born white).

NAOS, in Greek architecture, the most important portion of the enclosed part, or cella, of a temple. When the cella contains but one room, this is the naos; when it contains two, the naos is the larger of these, in which the statue of the deity is placed.

NAPA, a city of California, U.S.A., 11 m. N. of San Pablo bay and 40 m. N. by E. of San Francisco, at the head of navigation on the tidal Napa river; the county seat of Napa county. It is served by the Southern Pacific and electric railways, and by steamboats to points on San Francisco bay. Pop. 6,757 in 1920 (82% native white); estimated locally at 7,600 in 1928. It is the commercial and industrial centre of the fertile Napa valley, which is famous for its grapes, nuts, prunes, early pears, apples, oats, alfalfa, and other ranch products. The city's manufactures include shoes, gloves, shirts, athletic equipment, paper boxes, stone, dried fruits, butter, cheese, mineral water and grape juices. Napa was settled in 1831 and incorporated as a city in 1872.

NAPERVILLE, a city of Du Page county, Illinois, U.S.A., on the Burlington Route railway, 28 m. W. of Chicago. Pop. 3,830 in 1920; estimated locally at over 5,000 in 1928. It has orchid greenhouses, nurseries, poultry farms and several factories, and is the seat of North Central ("North-Western" until 1926) college, founded by the Evangelical Church in 1861 at Plainfield (Illinois) and moved to Naperville in 1870, and of the Evangelical Theological seminary (1910). The city was founded about 1831.

NAPHTALI was, according to Genesis xxx. 8, a son of Jacob by Rachel's handmaid Bilhah, and full brother of Dan. This may be no more than a reflection of the fact that geographically the tribes of Dan and Naphtali are closely associated. Not only did the land of Naphtali in northern Palestine border on that of Dan, but we find in Deut. xxxiii. 23 an indication that Naphtali dwelt near to Dan in the older seat of the latter tribe in the south-west. The story of the conflict against Sisera, Judges iv. *seq.*, associates Zebulun closely with Naphtali, and informs us that from Kadesh, the old Amorite city which was the chief place in Naphtali's territory, came the hero Barak. Naphtali, because of its exposed situation, suffered at the hands of Syria (1 Kings xv. 20); it was depopulated by Tiglath-Pileser (2 Kings xv. 29). The reference to Naphtali in the Blessing of Jacob, Genesis xlix. 21, is obscure and of uncertain interpretation. (W. L. W.)

NAPHTHA, a word originally applied to the more volatile kinds of petroleum, issuing from the ground in the Baku district of Russia and in Persia. It is the *ναφθα* of Dioscorides, and the *naphtha*, or *bitumen liquidum candidum* of Pliny. By the alchemists the word was used principally to distinguish various highly volatile, mobile and inflammable liquids, such as the ethers, sulphuric ether and acetic ether having been known respectively as *naphtha sulphurici* and *naphtha aceti*.

The term is now seldom used, either in commerce or in science, without a distinctive prefix, and we thus have the following:—

1. *Coal-tar Naphtha*.—A volatile commercial product obtained by the distillation of coal-tar. (See COAL-TAR.)

2. *Shale Naphtha*.—Obtained by distillation from the oil produced by the destructive distillation of bituminous shale. (See PARAFFIN.)

3. *Petroleum Naphtha*.—A name sometimes given (e.g., in the United States) to a portion of the more volatile hydrocarbons distilled from petroleum. (See PETROLEUM.)

4. *Wood Naphtha*.—Methyl alcohol (*q.v.*).

NAPHTHALENE, a hydrocarbon, $C_{10}H_8$, formed when many organic compounds, e.g., acetylene, ethylene, acetic acid, ether or camphor, are passed as vapours through a red-hot tube. This accounts for its presence in certain fractions of the coal-tar distillate (see COAL-TAR), where it was originally observed in 1819 by Garden and independently by Brande. Its composition was first determined by Faraday, in 1826. The amount of naphthalene produced during the manufacture of coal-gas varies with the type

of coal used and increases with rising temperature of carbonization; it rarely exceeds 10% of the tar distillate, and the usual amount is about 5%. Its presence among the products obtained by the modern low-temperature carbonization processes has not yet been established. Even when formed in only small amounts, naphthalene is frequently carried by the coal-gas through the various purifying chambers and escapes into the service pipes, where it gradually accumulates to such an extent as to necessitate its removal by mechanical means. Naphthalene also occurs in some natural mineral oils, but derivatives in nature are rare. Juglone (5-hydroxy-1:4-naphthoquinone), occurring in freshly-gathered walnut shells, and santonin and artemisin, the active principles of wormseed, are the chief.

When the "carbolic oil" fraction (boiling point 170° – 230° C) of the coal-tar distillate is allowed to cool, the crude naphthalene crystallizes out and is readily purified. The oily impurities are first removed by filtration; the naphthalene crystals are then hot-pressed, washed with hot caustic soda to remove acidic phenols (see CARBOLIC ACID) and then heated at 100° C for an hour with 5–10% of strong sulphuric acid to remove basic substances and any residual phenols. After further washings with dilute alkali and hot water, the naphthalene is finally distilled with steam or sublimed.

Properties and Uses.—Pure naphthalene crystallizes in white, shining plates, melting at 80° C, and boiling at 218° C. It possesses a characteristic tarry odour, a pungent taste, and is appreciably volatile even at ordinary temperatures. It is sparingly soluble in hot water and in petroleum spirit, but dissolves readily in benzene, alcohol and ether. With picric acid it forms a stable crystalline picrate, $C_{10}H_6$, $C_6H_2(NO_2)_3OH$; this, in the absence of other picrate-forming compounds, provides a method of estimating naphthalene. When heated in acetic acid solution with formaldehyde and a little sulphuric acid, naphthalene gives a resin, which, unlike phenolic resins, does not become infusible when baked. (See RESINS, SYNTHETIC.) The products obtained on oxidizing naphthalene vary considerably with the type of oxidizing agent employed. Potassium permanganate, in alkaline solution, gives phthalonic acid, but in acid solution phthalic acid is the chief product. Potassium dichromate and sulphuric acid, too, give phthalic acid, but with chromic acid in acetic acid solution, 1:4-naphthoquinone is mainly formed. The action of an excess of 100% sulphuric acid and mercuric sulphate at 200° C produces mainly phthalic acid, which was formerly manufactured by this method.

Naphthalene burns with a luminous, smoky flame, and is in consequence used for increasing the illuminating power of coal-gas. It is also utilized as a vermin killer (in the form of the so-called "white carbon" balls), though as its antiseptic properties are slight, it more frequently functions as a solid solvent for other substances, e.g., para-dichlorobenzene, of higher germicidal power. It is also a useful solvent for sulphur, phosphorus, metallic sulphides, and indigo. The value of naphthalene depends most, however, on its extensive employment in the manufacture of dyestuffs, of explosives, and of phthalic acid (*q.v.*), the last-named being manufactured by the oxidation of naphthalene in the vapour phase by air, using vanadium pentoxide or vanadyl chloride as catalyst. The derivatives most important to the dyestuffs manufacturer are the sulphonic acids of the naphthylamines, naphthols, aminonaphthols, and dihydroxynaphthalenes, but not all are of equal value. Indeed, only relatively few form azo-dyes which are completely satisfactory as regards solubility, fastness, tinctorial power and delicacy of shade. The market price of naphthalene varies of course with the degree of purity, but approximates to £14 per ton. Commercial naphthalene has setting point 79° C, and boiling point 217° C; it should volatilize completely, leaving no residue, and be free from phenols and quinoline bases; it should remain white in nitric acid (sp.gr. 1.42) for half an hour.

Constitution.—In the empirical formula, $C_{10}H_8$, for naphthalene, there are two more carbon atoms than hydrogen atoms, and from a consideration of its chemical properties, its products on disruption and from various modes of synthesizing it, naphthalene is best represented by formula I, or conventionally by formula

II, the carbon atoms, except the two "submerged" atoms, are

Formula I.

Formula II.

associated with a hydrogen atom each, numbered as shown. Although such a formula would appear to consist merely of two benzene rings, neither ring is in fact benzenoid in character until the unsaturation of the other has been destroyed (*see below*). Positions 1, 4, 5, 8 are termed α -positions; 2, 3, 6, 7 are β -positions. Among di-derivatives, as in the benzene series, the 1:2-position is *ortho*, 1:3-*meta*, and 1:4-*para*; of the heteronuclear di-derivatives, the only important names are those given to the 2:6- and the 1:8-, which are called respectively *amphi*- and *peri*-positions. Peri-substituted compounds react in many respects as though they were true *ortho*-compounds. For instance, naphthalene-1:8-dicarboxylic acid (naphthalic acid) easily forms an anhydride; the corresponding diketone (acenaphthene-quinone) readily condenses with *ortho*-diamines; 1:8-naphthylene-diamine combines with suitable organic substances to form another ring; while sultams I. (from *peri*-amino-sulpho-derivatives), sultones II. (from *peri*-hydroxy-sulpho-derivatives), and lactones III. (from *peri*-hydroxy-carboxy-derivatives) may be produced by

III.

the elimination of water. There are ten possible disubstitution products if the entering groups are the same, but if different, 14. The number of trisubstituted products is much greater.

When naphthalene is nitrated, aminated, chlorinated, brominated or iodinated, the entering group invariably replaces the hydrogen atom in the α -position. On sulphonation, however, both α - and β -positions may be occupied by the entering group, the amount of each monosulphonic acid depending on the temperature and duration of the reaction, and also to a lesser extent on the strength and quantity of the acid used. All other monosubstituted β -derivatives must be prepared by indirect processes. Even with one group already in the nucleus, in either the α - or the β -position, further substitution tends to take place at another α -position, though there are exceptions, again more especially on sulphonation.

NAPHTHALENE DERIVATIVES

Homologues.—The methyl, ethyl and other alkyl derivatives of naphthalene used to be of little importance, but they are now being investigated as low-temperature lubricating oils. α -Methylnaphthalene is a liquid which boils at 240° C; β -methylnaphthalene is a solid, melting at 32° C. Both are present in coal-tar, which also contains at least four dimethylnaphthalenes.

Chloronaphthalenes.—During the classical researches of Armstrong and Wynne on the constitution of naphthalene derivatives, the mono-, di- and tri-chloronaphthalenes (all of which—and there are 26—were prepared) were of the greatest scientific importance, in that any naphthalene compound of unknown configuration could be converted into the corresponding chloro-derivative, and its constitution thus established. Only α -chloronaphthalene and 1:4-dichloronaphthalene can, however, be produced cheaply; the former is manufactured by passing chlorine into boiling naphthalene in presence of ferric chloride, and is an oil, boiling at 263° C; its chlorine atom is more reactive than that in chlorobenzene. 1:4-Dichloronaphthalene, melting point 68° C, is pre-

pared by heating naphthalene with thionyl chloride at 140–160° C.

Naphthalene Chlorides.—Another type of chlorinated naphthalene is known in which the halogen atoms are associated with the carbon atoms of the nucleus without replacing the hydrogen atoms. These "additive" compounds, as they are called, are of little technical value, but their formation serves to show the unsaturated nature of the naphthalene nucleus. Naphthalene dichloride, $C_{10}H_8Cl_2$, is a yellow oil formed when the hydrocarbon is treated with potassium chlorate and hydrochloric acid. When heated to 50° C hydrogen chloride is eliminated, leaving α -chloronaphthalene. Naphthalene tetrachloride, $C_{10}H_4Cl_4$, formed when chlorine is passed into a chloroform solution of the hydrocarbon, melts at 182° C.

Nitronaphthalenes.— α -Nitronaphthalene, $C_{10}H_7NO_2$, prepared by the action of strong nitric acid on naphthalene, is readily soluble in benzene, ether and hot alcohol from which it crystallizes in yellow needles, melting point 61° C. It is not volatile in steam. Its technical importance is mainly due to the fact that on vigorous reduction it gives α -naphthylamine (*see below*). β -Nitronaphthalene is commercially unimportant because of its relative inaccessibility. The most convenient method of preparation is that of Vesely and Dvorak (1922), who obtained it in 28% yield by decomposing diazotized β -naphthylamine sulphate with copper bronze in presence of potassium nitrite. It crystallizes from dilute alcohol in yellow needles, melting point 79° C; unlike the α -compound, it is volatile in steam.

On further nitration with nitric acid in presence of sulphuric acid, α -nitronaphthalene yields a mixture of 1:5- and 1:8-dinitronaphthalenes, the former after purification melting at 216° C, and the latter at 170° C. A mixture of the same two components is obtained on dinitrating naphthalene itself. This crude mixture, when heated with sulphur and fuming sulphuric acid, or when dissolved in sulphuric acid and electrolysed at 130° C, furnishes naphthazarin, the bisulphite compound of which is the important black mordant dyestuff Naphthazarin S. For many years naphthazarin was assumed to be 5:6-dihydroxy- α -naphthoquinone, I., because of its similarity to alizarin (*q.v.*). In 1925, however, it was proved to possess the constitution II. Several tri- and

I.

II.

tetra-nitronaphthalenes have been described; some of them find a limited use in the manufacture of explosives.

Naphthoquinones.—Six different naphthoquinones, $C_{10}H_6O_2$, are theoretically possible, three homonuclear, *i.e.*, with the :CO groups in the same ring, and three heteronuclear (in different rings). Of these, only the 1:4-, the 1:2- and the 2:6-, together with a derivative of the 2:3-, have been prepared. 1:4-Naphthoquinone (I.), obtained in yellow plates by the oxidation of various α -derivatives of naphthalene with chromic acid, resembles

(I.)

(II.)

(III.)

benzoquinone in that it has a characteristic odour and is volatile in steam. A hydroxy-derivative of this quinone, juglone, affords a very delicate test of nickel, since in 1% alcoholic solution it gives a distinct violet colour with 0.001% of Ni. 1:2-Naphthoquinone (II.), obtained by oxidizing 2-amino- α -naphthol with ferric chloride, differs from the 1:4-quinone in being, like phenanthraquinone, odourless and non-volatile in steam. 2:6-Naphthoquinone (III.), too, is non-volatile and odourless, but similar to

benzoquinone in chemical properties; it is formed by the oxidation of the corresponding dihydroxynaphthalene with lead peroxide in benzene solution. The 1:2- and 2:6-quinones are red.

Naphthalenesulphonic Acids.—Naphthalene- α -sulphonic acid, $C_{10}H_7SO_3H$, predominates when the hydrocarbon is sulphonated below $80^\circ C$, the β -isomeride when the temperature of sulphonation is 160 – $180^\circ C$. Further sulphonation of the former yields 1:5- and 1:6-, and of the latter 2:7- and 2:6-disulphonic acids. Other disulphonic acids are obtainable by synthetic methods, and numerous tri- and tetra-sulphonic acids are also known. All these acids liberate hydrochloric acid from sodium chloride. They and their alkali salts are soluble in water, but the lead, barium and calcium salts often differ widely in solubility, and can occasionally be utilized in the separation of mixtures. The value of these polysulphonic acids depends largely on the ease with which they lose sulphonic groups or exchange them for hydroxyl groups, both changes taking place more readily from α - than from β -positions.

Naphthylamines (aminonaphthalenes).—Since sulphonation is the only convenient means of obtaining β -derivatives directly from the hydrocarbon, the manufacture of β -naphthylamine and its substitution products (from naphthalene- β -sulphonic acid *via* β -naphthol) differs from that of α -naphthylamine (which is easily accessible through α -nitronaphthalene). The two naphthylamines are the analogues of aniline (*q.v.*), but differ from it in some respects; they may, for instance, be prepared by heating the corresponding naphthol with the ammonia compound of zinc chloride or calcium chloride; aniline cannot easily be so obtained from phenol.

α -Naphthylamine, $C_{10}H_7NH_2$, is made in large quantities by reducing α -nitronaphthalene with soft iron borings ("swarf") and dilute hydrochloric acid at 50 – $70^\circ C$; milk of lime is then added to neutralize the acid, and the liberated amine distilled, either with superheated steam, or preferably in a vacuum. Further distillation and crystallization are necessary to obtain the pure product. If naphthalene is heated at $220^\circ C$ with sodamide in presence of phenol, α -naphthylamine is formed, hydrogen being evolved. It may also be prepared by heating α -naphthol with ammonium bisulphite under pressure or with ammonia-calcium chloride at $270^\circ C$. α -Naphthylamine is soluble in most solvents, and crystallizes when quite pure in colourless flat needles or scales, which melt at $51^\circ C$, and boil at $300^\circ C$. The technical product gradually acquires a greyish-violet colour when exposed to air, owing probably to the presence of easily oxidized 1:8-diaminonaphthalene. α -Naphthylamine can be readily distinguished from the β -isomeride by its faecal odour, by its slight volatility in steam, and by the azure-blue precipitate, soluble in chloroform, which aqueous solutions of its salts give when oxidized with ferric chloride. Diazo-solutions of amines couple with α -naphthylamine in the 4-position, or if this is occupied in the 2-position, giving aminoazo-compounds. If both positions are blocked, either one of the intruding substituents is removed, or azo-coupling does not take place.

α -Naphthylaminesulphonic acids can be prepared in several ways, of which the most important technically are (a) sulphonation of α -naphthylamine, (b) amination of α -naphtholsulphonic acids, using ammonia and ammonium sulphite, and (c) nitration of naphthalenesulphonic acids, with subsequent reduction. Of the seven possible monosulphonic acids of α -naphthylamine, all except the 3- acid are in common use; the most important is 1-naphthylamine-4-sulphonic acid (naphthionic acid), produced by "baking" α -naphthylamine acid sulphate at 180 – $200^\circ C$ in a vacuum, or by heating the amine with sulphuric acid at $170^\circ C$ in presence of 3% of oxalic acid. When diazotized it constitutes the first component of many azo-dyes of the fast red series. It also couples with diazotized bases forming ortho-azo-dyes, but in these circumstances the still intact amino-group in the 1-position cannot be further diazotized owing to the proximity of the diazo-complex; one of the best known dyes in this class is Congo red, from diazotized benzidine (*q.v.*) and two molecules of naphthionic acid.

β -Naphthylamine is manufactured in almost quantitative yield by heating in an autoclave under the pressure of 6 atmos. β -naphthol, 40% ammonium sulphite solution, and 20% ammonia in

suitable proportions at $150^\circ C$ for several hours. (This reaction, named after Bucherer, has an extensive application throughout the naphthalene series.) The crude naphthylamine is removed by filtration, washed with caustic soda to remove unchanged naphthol, and finally distilled in a vacuum to remove $\beta\beta'$ -dinaphthylamine, which is always produced in small quantity. When pure, β -naphthylamine crystallizes from alcohol in colourless, lustrous scales, melts at $112^\circ C$, and boils at $294^\circ C$. Unlike the α -isomeride, it is odourless, moderately volatile in steam, and appreciably soluble in hot water, and solutions of its salts give no colour with ferric chloride or other mild oxidizing agents.

The most important reactions used for the manufacture of β -naphthylaminesulphonic acids are (a) sulphonation of naphthylamine, (b) amination of naphtholsulphonic acids in presence of ammonium bisulphite, and (c) reduction of β -nitronaphthalenesulphonic acids. As sources of azo-dyes these acids are not so important as the α -amino-compounds; many of the dyestuffs derived from them are of little worth and, moreover, once they have coupled (in the α -position) with other diazotized amines, the contiguous β -amino-group cannot be itself diazotized. β -Naphthylamine-6-sulphonic acid (Brönner acid) and β -naphthylamine-3:6-disulphonic acid are among the more important. One valuable property, however, which the β -naphthylamine-di- and tri-sulphonic acids possess is that of exchanging an α -sulphonic group for a hydroxyl group when digested with caustic soda, thus producing the valuable aminonaphtholsulphonic acids; α -naphthylamine-di- (though not tri-) sulphonic acids under the same conditions exchange the amino-group for a hydroxyl group giving merely naphtholdisulphonic acids. The naphthylaminesulphonic acids of both the α - and β - series may be estimated by titration with diazotized *para*-nitraniline.

An important feature of sulphonic groups, not only in the naphthylamine and naphthol series, but also in naphthalenesulphonic acids, is the frequency with which they "migrate" from one position to another during the sulphonation process. This apparent shifting is due largely to hydrolysis of the sulphonic group, followed by resulphonation in another position under the altered conditions. For example, sulphonation of β -naphthol at the ordinary temperature gives the 1-, at $60^\circ C$ the 8-, and at $100^\circ C$ the 6-sulpho-derivative.

The ten possible *diaminonaphthalenes* have all been prepared, most of them by heating the corresponding aminonaphthol or dihydroxynaphthalene with ammonia under pressure, but reduction of nitronaphthylamines, of dinitronaphthalenes, or of azo-dyes furnishes others which would otherwise be difficult of access. They have found little application in the colour industry. 1:8-Naphthylenediamine, $C_{10}H_6(NH_2)_2$, melting point $67^\circ C$, is of interest because, like the true ortho-diamines (1:2- and 2:3-), it readily forms another ring by condensation with such substances as acetone, acetic anhydride, phosgene, ethyl oxalate and nitrous acid. The *diaminonaphthalenesulphonic acids* are unimportant.

Naphthols (hydroxynaphthalenes).—These industrially important substances are the naphthalene analogues of phenol (*see CARBOLIC ACID*), which they resemble in a general way. Nevertheless, there are certain important differences due to the greater reactivity of the hydroxyl group in the naphthols. For instance, the naphthols when heated under pressure with ammonia furnish the corresponding naphthylamines; they can be etherified when heated with alcohol and hydrochloric acid at $150^\circ C$; and they are converted into naphthyl ethers (dinaphthyl oxides) by boiling sulphuric acid. Phenol undergoes none of these reactions to any appreciable extent. The naphthols are said to occur in very small amount in high-boiling coal-tar fractions. Many tests have been devised for detecting and estimating traces of α - and β -naphthols in each other. Moreover, certain colour reactions are available: (1) ferric chloride, with which the α - isomeride gives an opalescence changing to a violet precipitate of $\alpha\alpha$ -dinaphthol, whereas the β gives a pale green colour changing to a white precipitate of $\beta\beta'$ -dinaphthol; (2) bleaching powder solution, α - giving a violet colour, and β - a pale yellow; (3) sodium hypiodite (α - gives a purple colour, and β - nil), and (4) titanil

sulphate (α - gives an intense green colour changing to reddish-violet on addition of acetic acid, and β - nil). Both α - and β -naphthols develop Prussian blue colorations with chloroform and caustic potash solution.

α -Naphthol, $C_{10}H_7OH$, is usually manufactured by adding sodium naphthalene- α -sulphonate to fused caustic soda in an open vessel at about $300^\circ C$, or by heating it with strong caustic soda solution in an autoclave at about $280^\circ C$ for 10–12 hours, whereby the formation of oxidation products attendant upon open pot fusions is avoided. If required quite free from β -naphthol (which is always present in α -naphthol prepared by fusion processes), it may be obtained by heating α -naphthylamine sulphate or hydrochloride with water at $200^\circ C$ under pressure for four hours. Another method consists in heating under pressure α -chloronaphthalene, caustic soda and methyl alcohol at $210^\circ C$ for several hours. α -Naphthol crystallizes in white, lustrous prisms, melting point $94^\circ C$, boiling point 278 – $280^\circ C$. It is readily soluble in most organic solvents and in caustic alkali solutions, but only sparingly in hot water. Unlike β -naphthol, it is volatile in steam at $100^\circ C$, and possesses a phenolic odour. α -Naphthol is more poisonous than β -naphthol, and finds no medicinal application. Nitrous acid converts it into a mixture of 2- and 4-nitroso- α -naphthol, the former preponderating. One chlorine atom can be introduced by using sulphuryl chloride to give 4-chloro- α -naphthol, but chlorination with chlorine leads to the formation of the 2:4-dichloro-derivative. Nitration gives, in the same way, not a mononitro-compound, but 2:4-dinitro- α -naphthol. The sodium salt of this substance, known variously in commerce as Martius yellow, Manchester yellow, or naphthalene yellow, was formerly used as a golden-yellow dye for silk and wool. It is easily removed from the fibre, however, and has been superseded. A closely related dyestuff of greater importance is naphthol yellow S (2:4-dinitro- α -naphthol-7-sulphonic acid).

The most important technical methods for the manufacture of α -naphtholsulphonic acids are (a) sulphonation of α -naphthol, (b) replacement of the amino-group of α -naphthylaminesulphonic acids by hydroxyl, through the diazo-reaction, (c) conversion of α -naphthylaminesulphonic acids by heating with sodium bisulphite solution (i.e., the reverse of Bucherer's reaction for the introduction for an amino-group), (d) exchange of one of the α -sulphonic groups in naphthalenepolysulphonic acids for hydroxyl by fusion with caustic alkali, and (e) similar exchange of the chlorine atom in α -chloronaphthalenesulphonic acids. The best known is 1-naphthol-4-sulphonic acid (Neville and Winther's acid) which is used for making a large number of azo-dyes.

β -Naphthol is invariably made technically by fusion of the sodium salt of naphthalene- β -sulphonic acid with caustic alkali, and is therefore liable to contain a small amount of the α -isomeride unless carefully purified. When pure it crystallizes in plates, melting point $122^\circ C$, boiling point 285 – $286^\circ C$. Its solubility in various solvents is similar to that of α -naphthol, but it is odourless, and appreciably volatile only in superheated steam. It has marked antiseptic properties, and its salicylate

, which is known in pharmacy as betol or

naphtholsalol, is useful medicinally. When ortho-aminoazotoluene is diazotized and coupled with β -naphthol, a dark reddish-brown powder, called scarlet red, is formed. This possesses valuable therapeutic properties, and is also used for stains in microscopy. The alkyl ethers of β -naphthol find scope as cheap perfumes. With nitrous acid, β -naphthol yields the 1-nitroso-derivative, which forms insoluble precipitates with certain metallic salts, thus enabling cobalt to be separated from nickel, iron from aluminium, and copper from cadmium, magnesium and zinc. These precipitates are easily converted into metallic oxides by ignition, and so afford a means of estimating cobalt, iron and copper. Chlorination of β -naphthol gives the 1-chloro-derivative, but on nitration 1:6-dinitro- β -naphthol is obtained. If β -naphthol is condensed in alcoholic solution with para-nitrosodimethylaniline

hydrochloride, an oxazine, Meldola's blue (dimethylaminonaphthophenoxazonium chloride), is formed (see DYES, SYNTHETIC).

The general methods available for the production of β -naphtholsulphonic acids are somewhat limited by the difference in reactivity between α - and β -sulphonic groups in the naphthalene nucleus. For instance, only from those disulphonic acids (and there are but two available, the 2:6- and 2:7-) containing both sulphonic groups in β -positions can a β -naphthol derivative be obtained by fusion with alkali, for if an α -sulphonic group be present it will be replaced preferentially. Furthermore, replacement of the β -amino-group by hydroxyl is usually impracticable, as the most convenient method of preparing the required β -naphthylaminesulphonic acids is from the β -naphtholsulphonic acids themselves. Fortunately a greater number of β -naphtholsulphonic acids can be obtained by direct sulphonation than in the α -series. Of these, β -naphthol-1-sulphonic acid (oxy-Tobias acid) is of little value for dyestuff purposes, but it is unique among the acids of the naphthalene series in that it undergoes a curious transformation when successively condensed with diazotized paranitraniline and treated with an excess of sodium hydroxide, a complex phthalazine I. being formed, instead of the usual para red II. β -Naphthol-6-sulphonic acid (Schaeffer acid), -8-sulphonic

I.

II.

acid (Croceine acid), -3:6-disulphonic acid (R-acid), -6:8-disulphonic acid (G-acid), and -3:6:8-trisulphonic acid, all produced by sulphonation of β -naphthol under varying conditions, are very important. G-Acid furnishes a series of valuable yellow or orange azo-dyes, hence its name (from Ger. *Gelbsäure* = yellow acid), in contradistinction to R-acid (from *Rotsäure* = red acid) which gives the more common red shades.

The dihydroxynaphthalenes and their sulphonic acids are of greater technical importance than the diamiononaphthalenes, especially 1:5-dihydroxynaphthalene, 1:8-dihydroxy-4-sulphonic acid, and 1:8-dihydroxy-3:6-disulphonic acid (chromotropic acid). When coupled with diazotized amines they furnish dyes which form insoluble lakes with iron, aluminium or chromium mordants.

Among the more important aminonaphtholsulphonic acids are 2-amino-5-naphthol-7-sulphonic acid (J-acid) (which, unlike its isomerides, endows many dyes of which it is a component with the property of dyeing unmordanted cotton), 2-amino-8-naphthol-6-sulphonic acid (γ -acid), and 1-amino-8-naphthol-3:6-disulphonic acid (H-acid), the last being one of the most valuable intermediates that the dyestuff industry possesses. H-Acid, as well as other 3:6-naphthalenedisulphonic acids, has also been employed in the synthesis of trypanocides for use in combating sleeping sickness. Several of the aminonaphtholsulphonic acids, e.g., "Eikonogen" and "Diogen," are used in photography.

Carboxylic Acids.—Only certain hydroxy-derivatives of α - and β -naphthoic acids are technically valuable. Their chief interest, with one exception, lies in one of the methods of preparation, for Kolbe's synthesis (the action of carbon dioxide under pressure on the dry sodium or potassium salt of the naphthol) furnishes from α -naphthol the 2-carboxy-acid, and from β -naphthol the 1-, 3-, or 6-carboxy-acid, according to the temperature. Of these, 2-hydroxy-3-naphthoic acid, melting point $216^\circ C$, is most important, since it gives rise to various anilides, toluidides, naphthylamides, etc., when heated in a solution of a tertiary base, such as dimethylaniline, with the appropriate amine in presence of phosphorus trichloride. These substances, of which the simplest,

melting point 243 – $244^\circ C$, has the trade

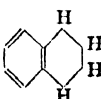

name "Naphthol AS" (Brenthol AS), possess a strong affinity for both natural and artificial fibres. When the material so impregnated is passed through a diazo-solution from *p*-nitroaniline or other aromatic base, coupling takes place inside rather than on the surface of the fibre, and the colours are much faster to light and washing than those from azo-dyes produced by merely "padding" the fibre with (say) β -naphthol. Various dyestuffs of this series are available for cotton, wool and artificial silks.

Hydrogenated Derivatives.—All the hydrogenated products of naphthalene, from dihydronaphthalene, $C_{10}H_{10}$, to decahydronaphthalene, $C_{10}H_{18}$, are known, each member having two hydrogen atoms more than its immediate predecessor. Three general methods are available for their preparation, in all of which, however, the products vary considerably with variations in the conditions. (1) Reduction with hydriodic acid: this method gives mixtures difficult to purify. Two intermediate products in the preparation of decahydronaphthalene by this method have been identified, viz., 1:4-dihydro- and 1:4:5:8-tetrahydro-naphthalene. (2) Reduction with sodium and an alcohol: by this method no more than four hydrogen atoms can be introduced into the naphthalene nucleus, no matter what alcohol is employed. Amyl alcohol and sodium yield 1:2:3:4-tetrahydronaphthalene, but the product when any other alcohol is used depends to a certain extent on the concentration of the sodium alcoholate, and also on the boiling point of the solvent. 1:4-Dihydronaphthalene I. is the first product and un-

less this isomerizes to 1:2-dihydronaphthalene II. hydrogenation can proceed no further. (3) Reduction with hydrogen in presence of a catalyst: the particular hydro-derivative obtained by this method depends upon a variety of conditions. Most important is the nature and oxygen content of the catalyst, but the degree of hydrogenation is dependent also on the temperature, pressure and duration of the reaction, and on whether the naphthalene reacts in the vapour or liquid phase or in solution.

Tetralin.—The method adopted for the manufacture of 1:2:3:4-

tetrahydronaphthalene  ("Tetralin") by the Tetralin Co.

at their works near Rosslau in Germany, where 120 tons per day can be produced, is briefly as follows: Commercially pure naphthalene, which contains sulphur compounds (e.g., thionaphthenes) equivalent to 0.25% of sulphur, is freed from them by heating with fuller's earth, kieselguhr or other absorbent material. If this were not done, the catalyst would be quickly poisoned and unable to function. The purified naphthalene is distilled into the hydrogenating autoclaves, which contain the catalyst (usually finely-divided nickel and copper oxide deposited on an inert medium), and hydrogen (freed from carbon monoxide and sulphur dioxide) is pumped in until at 200° C a pressure of about 220 lb. per sq. in. is attained. The agitated molten naphthalene rapidly takes up hydrogen until the tetrahydro-stage is reached, when the rate of absorption diminishes. The product is then distilled under reduced pressure, a fresh charge of molten naphthalene introduced, and the process repeated. As many as 40 hydrogenations can be effected before the catalyst has to be re-

activated. If "Decalin" (decahydronaphthalene)

is required, more hydrogen is introduced when the reaction attains the tetrahydro-stage, and the process continued.

Tetralin is a colourless liquid, boiling point 206°–208° C, flash point 78° C. It is insoluble in water and only sparingly soluble in ethyl alcohol (except after long standing, when oxidation products have affected its physical properties), but it mixes freely with amyl alcohol, butyl alcohol or benzene. It is a useful solvent for certain types of synthetic resins, essential and vegetable oils, waxes, rubber, sulphur and many organic substances and dyestuffs; it also finds application as a diluent in boot polishes. Both it and "tetralin extra" (a mixture of decalin and tetralin) are used in the manufacture of lacquers and varnishes; decalin alone has not such a powerful solvent action. Tetralin was used in Germany during the World War as a motor fuel in place of petrol, but under normal conditions its high flash point is a serious objection for such a purpose. When it is treated with concentrated sulphuric acid and the sulphonated oil neutralized with caustic soda, tetralin-soda sulphite, a white soapy substance, soluble in water and possessing a powerful emulsifying action, is formed: "Tetralol" (*ar*-tetra-hydro- β -naphthol) is used as a disinfecting soap; it is non-poisonous to man and may therefore also be employed for the preservation of fruit-trees.

When the naphthylamines and naphthols are reduced to their tetrahydro-derivatives with sodium in boiling amyl alcohol, two types of compounds are formed: (a) those in which the four hydrogen atoms are attached to the same ring as the original substituent, and (b) those in which the original substituent is in one ring and the four added hydrogen atoms are in the other. The members of class (a) are termed "alicyclic" (or *ac*-) derivatives, because they have become aliphatic in character; e.g., β -naphthylamine is hydrogenated to *ac*-tetrahydro- β -naphthyl-

alkaline, has an ammoniacal odour, absorbs carbon dioxide from the air, and cannot be diazotized. β -Naphthol similarly gives a secondary alcohol. The members of class (b) are termed "aromatic" (or *ar*-) because they still bear a close analogy to the corresponding compounds in the benzene series; e.g., α -naphthylamine and α -naphthol yield on hydrogenation *ar*-tetrahydro-

-OH), the properties of which closely resemble those of ortho-xylidine and ortho-xyleneol respectively.

NAPHTHOLS: *see* NAPHTHALENE.

NAPHTHYLAMINES: *see* NAPHTHALENE.

NAPIER, SIR CHARLES (1786–1860), British admiral, second son of the Hon. Charles Napier, R.N., and grandson of the 5th Lord Napier, was born at Merchiston Hall, near Falkirk, on March 6, 1786. He became a midshipman in 1800 and lieutenant in 1805. He was appointed to the "Courageux" (74), serving with her in the West Indies, and later was appointed commander of the "Pultusk" brig (Nov. 30, 1807). In August 1808 he was moved into the "Recruit," and in April 1809 took part in the capture of the "Hautpoul" and was promoted acting post captain. Coming home with a convoy, he was put on half pay and spent some time at the university of Edinburgh, and later visited Portugal. He served in 1811 in the Mediterranean and in 1813 on the coast of America. He spent his leisure in Italy and Paris, but was ruined by speculation in a steamboat company. In 1827 he was appointed to the "Galatea," was at the Azores when they were held by the count de Villa Flor for the queen of Portugal, and accepted the offer of the constitutional leaders to take command of the fleet (February 1833). With it he destroyed

the Miguelite fleet on July 5, and was struck off the English navy list. He commanded the Portuguese land forces in the defence of Lisbon (1834) and was made Count Cape St. Vincent in the peerage of Portugal.

Napier then returned to England, was restored to his former rank in 1836, and received the command of the "Powerful" in 1838. In 1840 he was made K.C.B. for his services as second in command in Syria. He was M.P. for Marylebone from 1842-46. He was promoted rear-admiral in 1846 and commanded the Channel fleet from 1846-48. In the Russian War he received the command of the Baltic fleet, and hoisted his flag in February 1854. He refused to attack Cronstadt, and a great outcry was raised against him for not obeying the orders of the Admiralty. He was not again offered a command. He was M.P. for Southwark from February 1855 until his death on Nov. 6, 1860.

See Major-General E. Napier's *Life and Correspondence of Admiral Sir Charles Napier, K.C.B.* (2 vols., 1862); Napier's own *War in Syria* (2 vols., 1842); *The Navy: its past and present state, in a series of letters*, edited by Sir W. F. Napier (1851); and *The History of the Baltic Campaign of 1854, from documents and other materials furnished by Vice-Admiral Sir C. Napier, K.C.B.* (1857). See also *The Life and Exploits of Commodore Napier* (1841); and *Life of Vice-Admiral Sir C. Napier* (1854).

NAPIER, SIR CHARLES JAMES (1782-1853), British soldier and statesman, was born in London, the eldest son of Colonel George Napier (a son of the 5th Lord Napier) and Lady Sarah Lennox, on Aug. 10, 1782. He was lieutenant in 1800 and captain in the staff corps under Sir John Moore. He became major in 1806 and served in the Danish campaign (1807) and in Portugal, but was badly wounded at Coa and Busaco. He took part in the pursuit of Masséna and became lieutenant-colonel (1811) of the 102nd regiment, which he thoroughly reorganized. At Bermuda in 1813 he served against the United States, but returned in 1815 and was made C.B. From 1822 to 1830 he was military resident of Cephalonia, where he met Lord Byron, and was recommended as commander-in-chief of the Greek forces. Napier declined, and, after trouble with Sir Frederick Adams, the high commissioner, he became commanding officer in the north of England during the Chartist riots (1839), although his sympathies were on the popular side. He accepted an Indian commission in 1841, and in September 1842 was ordered to Sind.

His command in Sind lasted until August 1847. He at once determined to seek the first opportunity of conquering the amirs. He was to be accompanied by James Outram (q.v.) who had been British resident in Sind during the Afghan War. On Feb. 15, 1843, Outram was treacherously assailed at Hyderabad, and on the 17th Napier attacked the Baluch army 30,000 strong, with but 2,800 men. With these 2,800 men, including the 22nd regiment, he won the brilliant and decisive victory of Miani, one of the most amazing in the history of the British army, in which generals had to fight like privates. In March he finally destroyed the army of the amirs at the battle of Hyderabad, and for this service received the K.C.B. Sind, when it came under British rule, was in a state of anarchy, for the Baluchis had formed a tyrannical military government. The native population was protected by Sir Charles Napier. The difficulties of administration were increased by the necessity of repressing the hill tribes, encouraged to lawless acts by the licence which followed the Afghan War; the later years were made very stormy by attacks in England on the policy of the conquest. Napier left Sind in August 1847 after quarreling with nearly every authority in India. His short stay in England was occupied with incessant struggles with the directors of the East India Company, but the panic in England which followed the news of the indecisive victory of Chillianwalla obliged the company to summon the greatest general of the day to command its armies.

Napier left for India at once, only to find that the victory of Gujrat had been won and the Sikh War was over. He was on good terms with the governor-general, Lord Dalhousie, until, in Dalhousie's absence at sea, Napier took upon himself, in face of a threat of mutiny, to alter the regulations regarding allowances to native troops. On Dalhousie's return he reprimanded the commander-in-chief, and reversed his decision. Napier immedi-

ately resigned, and, when Wellington repeated the reprimand, he returned to England.

He has been credited with foreseeing the Mutiny of 1857, and on the whole with justice. On one occasion he wrote that mutiny was "one of the greatest, if not the greatest, danger threatening India—a danger that may come unexpectedly, and if the first symptoms be not carefully treated, with a power to shake Leadenhall." On the mutiny of the 66th native regiment at Govindgarh he disbanded it, and handed its colours over to a Gurkha regiment, thus showing that he distrusted the high-class Brahman, and recognized the necessity of relying upon a more warlike and more disciplined race. His constitution was undermined by the Indian climate, and he died at Portsmouth on Aug. 29, 1853. The bronze statue of him by G. G. Adams, which stands in Trafalgar Square, London, was erected by public subscription, by far the greater number of the subscribers being, as the inscription records, private soldiers.

The chief authority for Sir Charles Napier's life is his *Life and Opinions* by his brother (1857); consult also MacColl, *Career and Character of C. J. Napier* (1857); M'Dougall, *General Sir C. J. Napier, Conqueror and Governor of Scinde* (1860); W. N. Bruce, *Sir Charles Napier* (1855); and T. R. E. Holmes, *Four Famous Soldiers* (1889). His own works are *Memoir on the Roads of Cephalonia* (1825); *The Colonies, treating of their value generally and of the Ionian Islands in particular*; *Strictures on the Administration of Sir F. Adam* (1833); *Colonization, particularly in Southern Australia* (1835); *Remarks on Military Law and the Punishment of Flogging* (1837); *A Dialogue on the Poor Laws* (1838?); *A Letter on the Defence of England by Corps of Volunteers and Militia* (1852); *Lights and Shadows of Military Life* (trans. from the French, 1840); and *A Letter to the Right Honourable Sir J. C. Hobhouse on the Baggage of the Indian Army* (1849); *Defects, Civil and Military, of the Indian Government* (1853); *William the Conqueror, a Historical Romance*, edited by Sir W. Napier (1858). On Sind, consult primarily Sir W. Napier, *The Conquest of Scinde* (1845); *The Administration of Scinde* (1851); *Compilation of General Orders issued by Sir C. Napier* (1850); and Outram, *The Conquest of Scinde, a Commentary* (1846). For his command-in-chief, and the controversy about his resignation, consult J. Mawson, *Records of the Indian Command of General Sir C. J. Napier* (Calcutta, 1851); *Minutes on the Resignation of the late General Sir C. Napier*, by Field-Marshal the Duke of Wellington, etc. (1854); *Comments by Sir W. Napier on a Memorandum of the Duke of Wellington* (1854); Sir William Napier, *General Sir C. Napier and the Directors of the East India Company* (1857); Sir W. Lee Warner, *Life of Lord Dalhousie* (1904).

NAPIER, JOHN (1550-1617), Scottish mathematician, the inventor of logarithms, was born in Merchiston near Edinburgh in 1550, and was the eighth Napier of Merchiston. He matriculated at St. Salvator's college, St. Andrews, in 1563. Very little is known of his life at this time, but it is plain from the "Discourse" which he prefixed to his *Plaine Discovery* that he was already a devoted adherent of the Protestant cause. From St. Andrews he went apparently to study in Paris, and travelled in Italy and Germany. But he was back at Merchiston in 1571, and in the next year married Elizabeth, daughter of Sir James Stirling. The son of this marriage was Archibald, Lord Napier. Elizabeth Napier died in 1579, and soon after Napier married Agnes Chisholm.

Napier was one of the Edinburgh commissioners to the General Assembly in 1588, and on Oct. 17, 1593, was a member of a committee nominated by a convention of delegates to make representations to the king at Jedburgh on the safety of the Church and the punishment of the Roman Catholic earls. He was a member of a similar delegation later in the month. On Jan. 29, 1594, Napier addressed to the king the letter which forms the dedication of his *Plaine Discovery of the whole Revelation of Saint John: set down in two treatises* . . . (Edinburgh, 1593). This book has a great place in the history of theology in Scotland, for it is the first important Scottish work on the interpretation of scripture.

After the publication of the *Plaine Discovery*, Napier seems to have occupied himself with the invention of secret instruments of war, for in the Bacon collection at Lambeth Palace there is a document, dated June 7, 1596, and signed by Napier, giving a list of his inventions for the defence of the country against the anticipated invasion by Philip of Spain. In 1614 appeared *Canonis Descriptio* embodying his invention of logarithms. Their nature is explained by reference to the motion of points in a straight line, and the principle upon which they are based is that of the correspondence of a geometrical and an arithmetical series of numbers.

The table gives the logarithms of sines for every minute to seven figures. This work contains the first announcement of logarithms to the world, the first table of logarithms and the first use of the name logarithm, which was invented by Napier.

In 1617 Napier published his *Rabdologia*. The method which Napier terms "Rabdologia" consists in the use of certain numerating rods for the performance of multiplications and divisions. These rods were commonly called "Napier's bones." The second method, which he calls the "Promptuarium Multiplicationis," involves the use of a number of lamellae or little plates of metal disposed in a box. In an appendix he gives his third method, "local arithmetic," which is performed on a chess-board, and depends, in principle, on the expression of numbers in the scale of radix 2. In the *Rabdologia* he gives the chronological order of his inventions.

John Napier died on April 4, 1617, the same year as that in which the *Rabdologia* was published.

The *Canonis Descriptio* on its publication in 1614 at once attracted the attention of Edward Wright, whose name is known in connection with improvements in navigation, and Henry Briggs, then professor of geometry at Gresham college, London. The former translated the work into English, but he died in 1615, and the translation was published by his son Samuel Wright in 1616. The logarithms introduced by Napier in the *Descriptio* are not the same as those now in common use, nor even the same as those now called Napierian or hyperbolic logarithms. The change from the original logarithms to common or decimal logarithms was made by both Napier and Briggs, and the first tables of decimal logarithms were calculated by Briggs, who published a small table, extending to 1,000, in 1617, and a large work, *Arithmetica Logarithmica*, containing logarithms of numbers to 30,000 and from 90,000 to 100,000, in 1624. (See LOGARITHM.) Napier's *Descriptio* of 1614 contains no explanation of the manner in which he had calculated his table. This account he kept back, as he himself states, in order to see from the reception met with by the *Descriptio* whether it would be acceptable. Though written before the *Descriptio* it had not been prepared for press at the time of his death, but was published by his son Robert in 1619 under the title *Mirifici Logarithmorum Canonis Constructio*. In this treatise (which was written before Napier had invented the name logarithm) logarithms are called "artificial numbers."

Napier's priority in the publication of the logarithms is unquestioned and only one other contemporary mathematician seems to have conceived the idea on which they depend.

An account of the contents of the manuscripts of John Napier in the possession of the family which survived a disastrous fire at the end of the 18th century was given by Mark Napier in the appendix to his *Memoirs of John Napier*, and the manuscripts themselves were edited in their entirety by him in 1839 under the title *De Arte Logistica Joannis Naperi Merchistonii Baronis Libri qui supersunt. Impressum Edinburgi M.DCCC.XXX.IX.*, as one of the publications of the Bannatyne club. The *Arithmetica* consists of three books, entitled: (1) *De Computationibus Quantitatum omnibus Logisticae speciebus communium*; (2) *De Logistica Arithmetica*; (3) *De Logistica Geometrica*. At the end of this book occurs the note—"I could find no more of this geometrical pairt among all his fragments." The *Algebra Joannis Naperi Merchistonii Baronis* consists of two books: (1) "De nominata Algebrae parte; (2) De positiva sive cossica Algebrae parte," and concludes with the words, "There is no more of his algebra orderlie sett down."

Besides the logarithms and the calculating rods or bones, Napier's name is attached to certain rules and formulae in spherical trigonometry. To him also seems to be due the first use of the decimal point in arithmetic. Decimal fractions were first introduced by Stevinus in his tract *La Disme*, published in 1585, but he used cumbrous exponents (numbers enclosed in circles) to distinguish the different denominations, primes, seconds, thirds, etc. In the *Rabdologia* Napier gives an "Admonitio pro Decimali Arithmetica," in which he commends the fractions of Stevinus and gives an example of their use, the division of 861094 by 432. The quotient is written 1993.273 in the work and 1993,273 in

the text. The decimal point is, however, used systematically in the *Constructio* (1619), there being perhaps two hundred decimal points altogether in the book.

Napier was in possession of all the conventions and attributes that enable the decimal point to complete so symmetrically our system of notation, viz. (1) he saw that a point or separatrix was quite enough to separate integers from decimals, and that no signs to indicate primes, seconds, etc., were required; (2) he used ciphers after the decimal point and preceding the first significant figure; and (3) he had no objection to a decimal standing by itself without any integer. Napier thus had complete command over decimal fractions and the use of the decimal point.

The bibliography of Napier's work attached to W. R. Macdonald's translation of the *Canonis Constructio* (1889) is complete and valuable. Napier's three mathematical works are reprinted by N. L. W. A. Gravelaar in *Verhandelingen der Kon. Akad. van Wet te Amsterdam* (1899).

NAPIER, SIR WILLIAM FRANCIS PATRICK (1785-1860), British soldier and military historian, third son of Colonel George Napier (1751-1804), was born at Celbridge, near Dublin, on Dec. 17, 1785. He became an ensign in the Royal Irish Artillery in 1800, but at once exchanged into the 62nd, and was put on half-pay in 1802. He afterwards became a cornet in the Blues, but he soon exchanged into the 52nd, which was about to be trained at Shorncliffe. Through Sir John Moore he soon obtained a company in the 43rd, joined that regiment at Shorncliffe and became a favourite with Moore. He served in Denmark, and was present at the engagement of Kioge, and, shortly afterwards bore himself nobly through the retreat to Corunna. In 1809 he became aide-de-camp to the duke of Richmond, lord lieutenant of Ireland, but joined the 43rd when that regiment was ordered again to Spain. With the light brigade (the 43rd, 52nd, and 95th), under the command of General Craufurd, he marched to Talavera and had an attack of pleurisy on the way. He refused to leave Spain, was wounded on the Coa, and shot near the spine at Casal Nova. After he left the lines of Torres Vedras he became brigade major, was present at Fuentes d'Onor, but had an attack of ague and was obliged to return to England. He married Caroline Amelia Fox, daughter of General Henry Fox. Three weeks afterwards he again started for Spain, and was present at the storming of Badajoz, where his great friend Colonel M'Leod was killed. He took command of the 43rd regiment (he was now a substantive major) and commanded it at the battle of Salamanca. At the battle of the Nivelle he secured the most strongly fortified part of Soult's position, practically without orders. He served with his regiment at the battles of the Nive, where he was wounded, Orthes, and Toulouse. For his services he was made brevet lieutenant-colonel, and one of the first C.B.'s. He then entered the military college at Farnham. He commanded his regiment in the invasion of France after Waterloo, and remained in France with the army of occupation until 1819, when he retired on half-pay. As this was not enough for him to live on with a wife and family, he studied with George Jones, the academician to become an artist.

His career was to be great in literature, not in art. The tendency appeared in a review of Jomini's works (*Edinburgh Rev.*) in 1821, and in 1823 Bickersteth (afterwards Lord Langdale) suggested to him writing a history of the Peninsular War. The duke of Wellington gave him much assistance, and handed over to him the whole of Joseph Bonaparte's correspondence which had been taken at the battle of Vittoria; this was all in cipher, but Mrs. Napier, with great patience, discovered the keys. Marshal Soult also took an active interest in the work and arranged for the French translation of Mathieu Dumas. In 1828 the first volume of the *History* appeared. The publisher, John Murray, was disappointed in the sale of the first volume and Napier published the remainder himself. But the excitement which followed the appearance of each volume is proved by the innumerable pamphlets issued by those who believed themselves to be attacked, and by personal altercations with many distinguished officers. This success was due to a combination of qualities which have justly secured for Napier the title of being the greatest military historian England has produced. When in 1840 the last volume of the

History was published, his fame was safely established.

His life during these years had been chiefly absorbed in his *History*, but he had warmly sympathized with the movement for political reform which was agitating England. The Radicals of Bath and many other cities and towns pressed him to enter parliament, and Napier was invited to become the military chief of a national guard to obtain reforms by force of arms. He refused the dangerous honour on the ground that he was in bad health and had a family of eight children. In 1830 he had been promoted colonel, and in 1842 he was made a major-general and given the lieutenant-governorship of Guernsey. Here he managed the relations between the soldiers and the inhabitants, and worked out proposals for a complete scheme of reform in the government of the island.

In 1845 he published his *History of the Conquest of Scinde*, and in 1851 the corresponding *History of the Administration of Scinde*. In 1847 he resigned his governorship, and in 1848 was made a K.C.B., and settled at Scinde House, Clapham Park. In 1851 he was promoted lieutenant-general. His time was occupied in defending his brother, and in revising the numerous editions of his *History* which were being called for. His energy is the more astonishing when it is remembered that he never recovered from the effects of the wound he had received at Casal Nova, and that he often had to lie on his back for months together. His domestic life was shadowed by the incurable affliction of his only son. He devoted himself to writing the life of his brother Charles, which appeared in 1857. He died on Feb. 12, 1860. Four months earlier he had been promoted to the full rank of general.

His brother, SIR GEORGE THOMAS NAPIER (1784-1855), entered the army in 1800, and served with distinction under Moore and Wellington in the Peninsula. He became major-general in 1837, K.C.B. in 1838 and lieutenant-general in 1846. He was governor and commander-in-chief at the Cape from 1839 to 1843. He was offered, but declined, the chief command in India after Chillianwalla, and also that of the Sardinian army in 1849. He became full general in 1854. He died at Geneva on Sept. 16, 1855. His autobiography, *Passages in the Early Military Life of General Sir G. T. Napier*, was published by his son, General W. C. E. Napier in 1885.

The youngest brother, HENRY EDWARD NAPIER (1789-1853), served in the navy during the Napoleonic wars, retired as a captain, and wrote a learned *Florentine History from the earliest authentic Records to the Accession of Ferdinand III. of Tuscany* (1846-1847).

For Sir William Napier's life, see his *Life and Letters*, edited by H. A. Bruce (Lord Aberdare) (1862).

NAPIER AND ETTRICK, FRANCIS NAPIER, Baron (1819-1898), British diplomatist, descended from the ancient Scottish family of Napier of Merchistoun, was born on Sept. 15, 1819, the son of William John, ninth Lord Napier. He entered the diplomatic service in 1840, and held successive posts at Vienna, Constantinople, Naples, Washington and The Hague. In 1860 he became ambassador at St. Petersburg, and in 1864 at Berlin. In 1866 he was appointed governor of Madras, and was at once confronted with a serious famine in the northern districts. In dealing with this and other problems he showed great activity and practical sense, and he encouraged public works, particularly irrigation. In 1872 he acted for a few months as Viceroy, after Lord Mayo's assassination; and on Lord Northbrook's appointment to the office he returned to England, being created a baron of the United Kingdom (Baron Ettrick of Ettrick) for his services. He was for a time a member of the London School Board, and was chairman of the Crofters' Commission in 1883, the result of which was the appointment of a permanent body to deal with questions affecting the Scottish crofters and cottars. He died at Florence on Dec. 19, 1898.

NAPIER OF MAGDALA, ROBERT CORNELIS NAPIER, 1ST BARON (1810-1890), British field-marshal, son of Major Charles Frederick Napier, was born at Colombo, Ceylon, on Dec. 6, 1810. He entered the Bengal Engineers from Addiscombe College in 1826, and after the usual course of instruction at Chatham, arrived in India in November 1828. For some

years he was employed in the irrigation branch of the public works department, and in 1838 he laid out the new hill station at Darjeeling. Promoted captain in January 1841, he was appointed to Sirhind, where he laid out cantonments on a new principle—known as the Napier system—for the troops returning from Afghanistan. In December 1845 he joined the army of the Sutlej, and commanded the Engineers at the battle of Mudki, where he had a horse shot under him. At the battle of Ferozeshah on Dec. 31 he again had his horse shot under him, and, joining the 31st Regiment on foot, was severely wounded in storming the entrenched Sikh camp. He was present at the battle of Soobraon on Feb. 10, 1846, and in the advance to Lahore. He was chief engineer at the reduction of Kote-Kangra by Brigadier-General Wheeler in May 1846, and received the thanks of government. He was then appointed consulting engineer to the Punjab resident and council of regency, but was again called to the field to direct the siege of Multan. He was wounded in the attack on the entrenched position in September 1848, but was present at the action of Shujabad, the capture of the suburbs, the successful storm of Multan on Jan. 23, 1849, and the surrender of the fort of Chinot. He then joined Lord Gough, took part, as commanding engineer of the right wing, in the battle of Gujrat in February 1849, accompanied Sir W. R. Gilbert in his pursuit of the Sikhs and Afghans, and was present at the passage of the Jhelum, the surrender of the Sikh army, and the surprise of Attock. At the close of the war Napier was appointed civil engineer to the board of administration of the annexed Punjab province, and carried out many important public works. In December 1852 he commanded a column in the first Hazara expedition, and in the following year against the Boris. He was appointed military secretary and adjutant-general to Sir James Outram's force for the relief of Lucknow in the Indian Mutiny in 1857, and was engaged in the actions which culminated in the first relief of Lucknow. He directed the defence of Lucknow until the second relief, when he was severely wounded in crossing an open space with Outram and Havelock to meet Colin Campbell. He was chief of the staff to Outram in the defence of the Alambagh position, and drew up the plan of operations for the attack of Lucknow, which was approved by Campbell and carried out by Napier, as brigadier-general commanding the Engineers, in March 1858. On the fall of Lucknow Napier received the C.B. He joined Sir Hugh Rose as second-in-command in his march on Gwalior, and commanded the 2nd brigade at the action of Morar on June 16. On the fall of Gwalior he was entrusted with the task of pursuing the enemy. With only 700 men he came up with Tantia Topi and 12,000 men on the plains of Jaora Alipur and completely defeated him, capturing all his guns (25), ammunition and baggage. On Rose's departure he took command of the Gwalior division, captured Paori in August, routed Ferozeshah, a prince of the house of Delhi, at Ranode in December, and in January 1859, succeeded in securing the surrender of Man Singh and Tantia Topi, which ended the war. For his services Napier received the thanks of parliament and of the Indian government, and was made K.C.B.

In January 1860 Napier was appointed to the command of the 2nd division of the expedition to China under Sir Hope Grant, and took part in the action of Sinho, the storm of the Peiho forts, and the entry to Peking. For the next four years Napier was military member of the council of the governor-general of India and, on the sudden death of Lord Elgin, for a short time acted as governor-general, until the arrival of Sir W. T. Denison from Madras. In January 1865 he was given the command of the Bombay army; in March 1867 he was promoted lieutenant-general, and, later in that year, appointed to command the expedition to Abyssinia, selecting his own troops and making all the preparations for the campaign. He arrived at Annesley Bay in the Red Sea in January 1868, reached Magdala, 420 m. from the coast, in April; stormed the stronghold, freed the captives, razed the place to the ground, returned to the coast, and on the 18th June the last man of the expedition had left Africa. He received for his services the thanks of parliament, a pension, a peerage, the G.C.B., the G.C.S.I., and many academic honors. He held the

command-in-chief in India for six years from 1870, during which he did much to benefit the army and to encourage good shooting. He was promoted general in 1874, and appointed a colonel-commandant of the Royal Engineers. In 1876 he was the guest of the German crown prince at the military manoeuvres, and from that year until 1883 held the government and command of Gibraltar. In the critical state of affairs in 1877 he was nominated commander-in-chief of the force which it was proposed to send to Constantinople. On Jan. 1, 1883 he was promoted to be field-marshal, and in December 1886 appointed Constable of the Tower of London. He died in London on Jan. 14, 1890.

See H. D. Napier, *Field Marshal Lord Napier of Magdala* (1927).

NAPIER, a seaport on the east coast of North Island, New Zealand, capital of the provincial district of Hawke's Bay, 200 m. by rail N.E. of Wellington. Pop. (1927) 18,680. The main portion of the town stretches along the flat shoreland of Hawke's Bay, while the suburbs extend over the hills to the north. The site consists of a picturesque peninsula known as Scinde Island. The harbour (Port Ahuriri) is sheltered by a breakwater. The cathedral church of St. John (1888) for the bishopric of Waiapu, is one of the finest ecclesiastical buildings in New Zealand, imitating the Early English style in brick. The district is agricultural, and wool, frozen meats and fruit are exported.

NAPLES (Ital. *Napoli*, and Lat. *Neapolis*), formerly the capital of the kingdom of the Two Sicilies, and since 1860 the chief town of the province which bears its name. It was the largest city in the country in 1901, containing 547,503 inhabitants, but has now been outstripped by Milan. Its population in 1921 was 771,857 (town), 772,405 (commune). It is the see of a cardinal archbishop; the residence of the general commanding the X. Army Corps and of the admiral commanding the second Naval Department of Italy; and it possesses also an ancient and important university. Since 1925 the province has been placed under a high commissioner.

Naples disputes with Constantinople the claim of occupying the most beautiful site in Europe. It is situated on the northern shore of the Bay of Naples (*Sinus Cumanus*), in $40^{\circ} 52' N.$, $14^{\circ} 15' 45'' E.$, as taken from the lighthouse on the mole. By rail it is distant 135 m. from Rome, by the direct line, and 155 by the older line via Cassino. (For map, see ITALY.) The circuit of the bay is about 35 m. from the capo di Miseno on the north-west to the Punta della Campanella on the south-east, or more than 52 m. if the islands of Ischia, at the north-west, and of Capri, at the south entrance, be included. At its opening between these two islands it is 14 m. broad; while another 4 m. separates Capri from the mainland at the Punta della Campanella, and from the opening to its head at Portici the distance is 15 miles. It affords good anchorage, with nearly 7 fathoms of water, and is well sheltered, except from winds which blow from points between south-east and south-west.

On the north-east shore east of Naples is an extensive flat, forming part of the ancient *Campania Felix*, and watered by the small stream Sebeto and by the Sarno, which last, in classical times, formed the port of Pompeii. From this flat, between the sea and the range of the Apennines, rises Mt. Vesuvius, at the base of which, on or near the sea-shore, are populous villages as well as the classic sites of Herculaneum and Pompeii. At the south-east extremity of the plain, 3 m. beyond the outlet of the Sarno, a great offshoot of the Apennines, branching from the main range near Cava, and projecting as a peninsula more than 12 m. W., divides the Bay of Naples from the Bay of Salerno (*Sinus Paestanus*), and ends in the bold promontory of the Punta della Campanella (Promontorium Minervae), which is separated by a strait of 4 m. from Capri. On the north slope of this peninsula, where the plain ends and the coast abruptly bends to the west, stands the town of Castellammare di Stabia, at the foot of Mt. Sant' Angelo, which rises to a height of 4,722 feet.

The north-west shore to the west of Naples is more broken and irregular. The promontory of Posilipo, which projects due south, divides this part of the bay into two smaller bays—the eastern, with the city of Naples, and the western, or Bay of Baiae, which is sheltered from all winds. A tunnel through the

promontory, 2,244 ft. long, 21 ft. broad, and in some places as much as 70 ft. high, possibly constructed by Marcus Agrippa in 27 B.C., forms the so-called grotto of Posilipo; at the Naples end stands the reputed tomb of Virgil, which has recently been restored. Beyond Posilipo is the small island of Nisida (*Nesìs*); and at a short distance inland are the extinct craters of Solfatara and Astroni and the lake of Agnano. Farther west, on the coast, and provided with a convenient harbour, stands Pozzuoli (*Puteoli*), containing many Roman remains, and beyond it, round the Bay of Baiae, are Monte Nuovo, a hill thrown up in a single night in Sept. 1538; the classic site of Baiae; the Lucrine lake; Lake Avernus; the Lake of Fusaro (*Acherusia Palus*); and the port and promontory of Misenum. Still farther to the south-west lie the islands of Procida (*Prochyta*) and Ischia (*Pitheculus*, *Aenaria* or *Inarime*), which divide the Bay of Naples from the extensive Bay of Gaeta. All this country was comprised in classical times under the title of the *Phlegrean Fields*, and was certainly then more actively volcanic than it now is, although the severe shock of earthquake which occurred in the island of Ischia in 1883, completely destroyed Casamicciola, and did serious damage to Forio, Lacco Ameno and Serrara Fontana, shows that there is great seismic activity in the locality. The whole region abounds with fissures, from which steam highly charged with hydrochloric acid is continually issuing, and in many places boiling water is found at a very few feet below the surface.

The city of Naples is built at the base and on the slopes of a range of volcanic hills, and, rising from the shore like a theatre, is seen to best advantage from the sea. From the summit occupied by the castle of St. Elmo a transverse ridge runs south to form the promontory of Pizzofalcone, and divides the city into two natural crescents. The western crescent, known as the Chiaja ward, though merely a long narrow strip between the sea and Vomero hill, is the fashionable quarter most frequented by foreign residents and visitors. A fine broad street, the Riviera di Chiaja, was begun at the close of the 16th century by Count d'Olivares, and completed by the duke de Medina Celi (1695-1700), running for a mile and a half from east to west, ending

WEATHER GRAPH OF NAPLES. THE MERCURY INDICATES THE NORMAL MEAN TEMPERATURE. THE CURVE SHOWS THE NORMAL MONTHLY MEAN TEMPERATURE. THE COLUMNS INDICATE THE NORMAL MONTHLY PRECIPITATION

in the quarter of Mergellina and Piedigrotta, at the foot of the hill of Posilipo. In front lie the public gardens of the Villa Nazionale, the chief promenade of the city, which were first laid out in 1780, and have been successively extended in 1807, in 1834, and again in recent years; and the whole edge of the bay from the Castel dell' Ovo to Mergellina is lined by a massive embankment and carriage-way, the Via Caracciolo, constructed in 1875-81. The eastern crescent includes by far the largest, as well as the oldest, portion of Naples.

The best known thoroughfare is the historic Toledo (officially Via Roma), which runs almost due north from the Piazza del Plebiscito in front of the Palazzo Reale, till, as Via Nuova di Capodimonte, crossing the Ponte della Sanità (constructed by

Murat across the valley between Santa Teresa and Capodimonte), it reaches the gates of the Capodimonte palace, thus dividing the city into two parts. A fine street, the Corso Vittorio Emanuele, winds along the slopes behind the city from the Mergellina railway station till it reaches the museum by the Via Salvatore Rosa. The character of the shore of the eastern crescent has been much altered by the new harbour works, which, with the wharves and warehouses, have absorbed the Villa del Popolo, or People's Park, originally constructed on land reclaimed from the bay. The two crescents have now been united by the construction of a connecting thoroughfare on the seaward side of the Castel Nuovo, the royal palace, and the hill of Pizzofalcone; while a tunnel (the Galleria della Vittoria) has been cut under this hill, thus further uniting the east and west halves of the city. There is also a metropolitan underground railway between the central station at Naples and Pozzuoli.

The streets of Naples are generally well-paved with large blocks of lava or volcanic basalt. In the older districts there is a countless variety of narrow gloomy streets, many of them steep. The houses are mostly five or six storeys high, are covered with stucco made of a kind of pozzolana, which hardens by exposure, and have large balconies and flat roofs. The castle of S. Elmo (S. Erasmus), which dominates the whole city, had its origin in a fort (Belforte) erected by King Robert the Wise in 1329. The present building, with its rock-hewn fosses and massive ramparts, was constructed by Don Pedro de Toledo in 1537-46, and was long considered practically impregnable. It is now a military prison. On a small island (I. del Salvatore, the *Megaritis* of Pliny), now joined to the shore at the foot of the Pizzofalcone by an arch-supported causeway, stands the Castel dell' Ovo, restored in the 16th century. Castel Nuovo, a very picturesque building constructed near the harbour in 1279-82 by Charles I. of Anjou, contains between the round towers of its façade the triumphal arch erected in 1455-58 to Alfonso I. In the interior is a fine Gothic hall. (See CELESTINE V.) The whole building has recently been restored. Castel del Carmine was demolished in 1906. The royal palace, begun in 1600 from designs by Domenico Fontana, partly burned in 1837, and repaired and enlarged by Ferdinand II., is an enormous building with a sea frontage of 800 ft. and a main façade 554 ft. long and 95 ft. high, exhibiting the Doric, Ionic and Composite orders in its three storeys. It now contains the important National Library (Biblioteca Nazionale Vittorio Emanuele III.) with valuable books and mss., including mss. recovered from Austria after the war, which had been removed to Vienna by Charles V. Another royal palace, that of Capodimonte, contains a gallery of modern pictures and a fine collection of 18th century Neapolitan porcelain.

Naples has 237 churches and 57 chapels. Most of the churches are notable rather for rich internal decoration than for architectural beauty. The cathedral of St. Januarius was erected in 1294-1323. The general plan is that of a basilica with a nave and two (Gothic vaulted) aisles separated by pilasters. The western façade was completed in 1906. Beneath the high altar is a subterranean chapel containing the tomb of St. Januarius (San Gennaro), the patron saint of the city; in the right aisle there is a chapel (Cappella del Tesoro) built between 1608 and 1637 in popular recognition of his having saved Naples in 1527 "from famine, war, plague and the fire of Vesuvius"; and in a silver tabernacle behind the high altar of this chapel are preserved the two phials partially filled with his blood, the periodical liquefaction of which forms a prominent feature in the religious life of the city. Accessible by a door in the left aisle of the cathedral is the church of Sta. Restituta, a basilica of the 4th century. Its baptistery contains important mosaics of that period. Santa Chiara (14th century, richly restored in the baroque style in the 18th) is interesting for a fresco ascribed to Giotto (at one time there were many more), and monuments to Robert the Wise, his son's wife, Mary of Valois, and his daughter Mary, empress of Constantinople.

San Domenico Maggiore, founded by Charles II. in 1289, but completely restored later, has an effective interior particularly rich in Renaissance sculpture. In the neighbouring monastery is

shown the cell of S. Thomas Aquinas. San Filippo Neri or dei Gerolomini, erected in 1592-1619, has a white marble façade and contains the tombstone of Giambattista Vico. Sta. Maria del Parto, in the Chiaja, contains the tomb of Sannazaro, and is named after his poem, *De Partu Virginis*. San Francesco di Paola, opposite the royal palace, is an imitation of the Pantheon at Rome, by Pietro Bianchi of Lugano (1815-18). The church of the Certosa (Carthusian monastery) of San Martino, has now become a museum. Dating from the 14th century, and restored in the 17th, it is a building of extraordinary richness of decoration, with paintings and sculpture by Guido Reni, Lanfranco, Caravaggio, D'Arpino, Solimena, Luca Giordano and Ribera. The monastery has been transformed into a mediaeval museum. The view from the south-western balcony is incomparable.

Other churches with interesting monuments are Sant' Anna dei Lombardi (the church of Monte Oliveto), built in 1414, which contains some splendid marble Renaissance sculpture; Sant' Angelo a Nilo, which contains the tomb of Cardinal Brancaccio, the joint work of Donatello and Michelozzo (1426-28), San Giovanni a Carbonara, built in 1343 and enlarged by King Ladislaus in 1400, which contains among much other remarkable sculpture the tomb of the king, the masterpiece of Andrea da Firenze (1428), and that of Gianni Caracciolo, the favourite of Joanna II., who was murdered in 1432 (the chapel in which it stands has one of the earliest majolica pavements in Italy); San Lorenzo (13th century), the Royal Church of the House of Anjou, and S. Maria Donna Regina, with its frescoes by Pietro Cavallini. The catacombs of S. Gennaro (2nd century) are in many respects not inferior to those at Rome.

Of the secular institutions in Naples none is more remarkable than the National Museum, formerly known as the Museo Borbonico. The building was put to its present use in 1790, when Ferdinand IV. placed in it the Farnese collection, which he had inherited from his father, and all the specimens from Herculaneum, Pompeii, Stabiae, Puteoli, Paestum, etc., which till then had been housed in the palace at Portici. Vast numbers of objects have since been added to it, both by purchase and from excavations, and it is now unique as a treasure house of Italo-Greek and Roman antiquities, besides containing important pictures.

The building, as now arranged, contains the large bronzes and statues on the ground floor; a gallery of Pompeian frescoes and mosaics in the entresol; the picture gallery, papyri, terra cottas and small bronzes, on the first floor; and the glass, jewellery, arms, gems, and the collection of Italo-Greek vases, on the second floor. The large bronzes are almost the only ones which have survived from classical times, the most famous of them being the seated Mercury and the dancing Faun; the marbles reckon among their vast number the Psyche, the Capuan Venus, as well as the huge group called the Toro Farnese (Amphion and Zethus tying Dirce to the horns of the bull), the Farnese Hercules, the excellent though late statues of the Balbi on horseback, and a very fine collection of ancient portrait busts.

The Galleria Umberto I. and Galleria Principe di Napoli somewhat resemble the Milan arcade. The Borsa (or exchange) is a fine building in the Piazza of the same name, built over the remains of the very ancient church of Sant' Aspreno, which are still preserved in the crypt. In front of it is the fine 16th century Fontana Medina.

Educational and Learned Institutions.—The university of Naples was founded by Frederick II. in 1224, and is well equipped with zoological, mineralogical and geological museums, a physiological institute, a cabinet of anthropology, and botanical gardens. The buildings were originally erected in 1557 for the use of the Jesuits. The new building, completed in 1906, faces the Corso Umberto I. (Rettifilo), the street from the Borsa to the railway station. The famous zoological station at Naples, whose aquarium is the principal building in the Villa Nazionale, was founded by Dr. Dohrn in 1872; the marine flora and fauna of the neighbourhood are more varied than those of any district in Europe. The chief universities of the world pay £100 a year for tables to which they send students. The astronomical observatory is situated on the hill of Capodimonte.

The Royal Society of Naples, dating from 1756, is divided into three academies, namely, moral and political; physical and mathematical; letters, archaeology and fine arts. The famous Accademia Pontaniana, founded by Antonio Becardella and J. J. Pontanus in 1442, was restored in 1808 and still exists. The Royal School for Oriental Languages owes its existence to Matteo Ripa, who in 1732 established a school for Chinese missionaries. The Royal Conservatory of Music in S. Pietro a Majella has existed in one form or other since 1760, and has had many famous pupils.

Elementary education has been greatly improved. Whereas in 1925 the schools were utterly insufficient, the attendances have risen from 42,000 to 51,000 in 1928, out of the 90,000 who should by law attend. The higher grade schools are also numerous, and there are special foreign schools, established by private enterprise.

The State archives in Vico San Severino e Sossio contain all the records of past Governments; the Notarial archives in Via San Paolo contain all the original notarial acts from 1450 onwards, to the number of 800,000. The Società di Storia Patria, established in 1875 to record all details of the history of the locality, has a good library also.

The San Carlo opera house, with its area of 5,157 sq. yd. and its stalls capable of seating 1,000 spectators, is one of the largest in Europe. It was originally built in 1737 under Charles III., but was destroyed by fire in 1816 and completely rebuilt. The Mercadante dates from 1778.

Charitable institutions are numerous in Naples. The Reclusorio or poorhouse was founded in the 18th century, and besides being a refuge for the indigent poor has a series of industrial schools attached, at which foundling boys are educated and taught trades. There are also several hospitals, the largest being the Incurabili, founded in 1519.

Harbour.—At a very early date the original harbour at Naples, now known in its greatly reduced state as Porto Piccolo, and fit only for boats and lighters, became too small. In 1302 Charles II. of Anjou began the construction of the Porto Grande by forming the Molo Grande or San Gennaro, which stretched eastward into the bay, and was terminated by a lighthouse in the 15th century. By the addition of a new pier running north-east from the lighthouse, and protected by a heavily armed battery, Charles III. in 1740 added greatly to the safety of the harbour. In 1826 the open area to the south of the Porto Grande was formed into the Porto Militare by the construction of the Molo San Vincenzo, 1,200 ft. long. The lengthening of the Molo San Vincenzo to a total of more than 5,000 ft., and the construction of curving moles on the east to meet it, has formed a large outer basin, the Avamposto, and an inner harbour (Porto Mercantile). New quays have been made all the way from the old Immacolatella landing-place to the Capitaneria di Porto, close to which is the marine railway station, with piers such that the largest liner can lie alongside the jetty. The depth of this new harbour is from 25 to 30 feet. To the east are dock basins, silos for grain and other warehouses. In 1926 the total tonnage entering the port amounted to 8,540,025 tons in 9,536 vessels, while the clearances were almost identical; 1,711,500 tons of goods were imported, and 422,137 exported (including coastwise trade); while the passenger traffic was 650,503 embarked, and 627,378 disembarked. The difference is accounted for by the excess of Italian emigrants over those returning from abroad; while the figures are enormously swollen by the passengers on the night mail boats to and from Palermo. The specialties of Naples are the manufacture of coral, tortoise-shell, kid gloves and macaroni, but it has been growing also as an industrial centre. The port of Naples is second only to that of Genoa.

Water Supply.—Naples has as fine a water supply as any city in Europe, derived from the hills in the neighbourhood of Avellino. It is received in a covered masonry canal, whence it flows in iron pipes till it reaches five enormous reservoirs constructed just opposite to the entrance gates of the royal palace at Capodimonte. Hence it comes by natural gravitation into the town at a pressure of five atmospheres, so that it supplies the highest parts of the town with abundant water. The supply was brought into the town just after the terrible cholera outbreak of

1884. The effect on the health of the city has been extraordinary. Cholera epidemics, which used to be frequent, have become things of the past, and there is now abundant water.

Modern Growth.—Naples has increased in modern times at an enormous rate. On the large areas reclaimed from the sea, hotels and mansions let in flats have been erected. The gardens at the west end of the town are all built over. The Vomero is now an important suburb. The commune has been built over in every direction, one great incentive being the creation of an industrial zone to the eastward of the city, set aside for the purpose of industrial development. It now contains a large number of factories for spinning silk, cotton, jute and wool, and the making of railway plant, automobiles, the building of ships, etc. After the cholera epidemic of 1884, Depretis, then premier, visited Naples, and uttered the famous dictum "*Bisogna sventrare Napoli*"—"Naples must be disembowelled!" The worst slums, which lay between the centre of the town and the railway station, were pulled down and a wide street was constructed from the centre of the town to the eastward. A large working-class quarter was erected to the north and beyond the railway station, known as the Rione Vasto. There are also new middle-class quarters at Santa Lucia, Vomero Nuovo and Sant' Efrema, Poggioreale and Fuorigrotta, and better houses on the Riviera di Chiaja, Via Elena and Via Caracciolo at Mergellina, Via Partenope near the Chiatamone, and an aristocratic quarter in the large extensions made in the Rione Amedeo. The narrow alleys of Porto, Pendino and Mercato have nearly all disappeared, and old Naples has been vanishing day by day. About 50,000,000 lire were assigned to Naples in 1927-28 for public works.

Folk-lore.—The charms against the Evil Eye used by the Neapolitans are derived from classical legends. They are: first, the sprig of rue in silver, with sundry emblems attached to it, all of which refer to the worship of Diana, whose shrine at Capua was of considerable importance; secondly, the serpent charms, which formed part of the worship of Aesculapius, and were no doubt derived largely from the ancient eastern opiolatry; and lastly, charms derived from the legends of the Sirens.

History.—All ancient writers agree in representing Naples as a Greek settlement. The earliest Greek settlement in the neighbourhood was at Pithecusa (Ischia), but the colonists, being driven out of the island by the frequent earthquakes, settled on the mainland at Cumae, where they found a natural acropolis of great strategic value. From Cumae they founded Dicaearchia (Pozzuoli) and subsequently Parthenope or Palaeopolis, where Naples now stands, upon the splendid natural acropolis formed by the hill of Pizzofalcone, defended on the land side by a fosse which is now the Strada di Chiaja, and a massive wall, of which remains may still be traced at the back of the existing houses. To the colonists of Parthenope there came afterwards a considerable addition from Athens and Chalcis, and they built themselves a town which they called *Neapolis*, or the "new city," in contradistinction to the old settlement, which in consequence was styled Palaeopolis or the "old city."

In 328 B.C. the Palaeopolitans having provoked the hostility of Rome by their incursions upon her Campanian allies, the consul Publius Philo marched against them, and laid regular siege to Palaeopolis; at length the city was betrayed into the hands of the Romans. Neapolis, perhaps, surrendered without resistance, as it was received on favourable terms, had its liberties secured by a treaty, and obtained the chief authority. From that time Palaeopolis totally disappeared from history, and Neapolis became an allied city (*foederata civitas*)—a dependency of Rome, to which it remained faithful. In 280 B.C. Pyrrhus unsuccessfully attacked its walls; and in the Second Punic War Hannibal was deterred by their strength from attempting to make himself master of the town. During the civil wars of Marius and Sulla a body of partisans of the latter, having entered it by treachery (82 B.C.), massacred the inhabitants; but Neapolis soon recovered, as it was again a flourishing city in the time of Cicero.

Neapolis long retained its Greek culture and institutions; and even at the time of Strabo it had gymnasia and quinquennial games, and was divided into *phratræ* after the Greek fashion.

NAPLES, THE METROPOLIS OF SOUTHERN ITALY

1. View of the city of Naples, the bay, and Mount Vesuvius from the Corso Vittorio Emmanuele, a winding driveway which ascends the slopes above the city. The massive structure in the distance at the right is the Castel Nuovo (13th century), long a royal and vice-regal residence. Extending into the bay to the right of the castle is the Molo San Vincenzo, off which the largest ocean liners are moored. Commercial shipping is chiefly served at the Molo San Gennaro and Molo Orientale further to the left
2. A narrow street in Naples characteristic of the older city
3. Typical Neapolitan street scene in the newer part of the city, showing the five and six storey, densely populated tenements with shops on the street level
4. Via Roma, still popularly called the Via Toledo, after its founder Don Pedro di Toledo (1532-54), viceroy during the Spanish regime. With its continuation, the Via Enrico Persina, this street runs in a nearly straight line for 1½ miles, from the Palazzo Reale to the Museo Nazionale. It is one of the busiest streets of the modern city

Many of the Romans of the upper classes, from a love of Greek manners and literature, resorted to Neapolis, either for education and the cultivation of gymnastic exercises or for the enjoyment of music and of a soft and luxurious climate. It was the favourite residence of many of the emperors; Nero made his first appearance on the stage in one of its theatres; Titus assumed the office of its archon; and Hadrian became its demarch. It was chiefly at Neapolis that Virgil composed his *Georgics*; and he desired to be buried on the hill of Pausilypon, the modern Posilipo, in its Neighbourhood, though his traditional tomb is really a *columbarium* of some family unknown. It was also the favourite residence of the poets Statius (A.D. 61) and Silus Italicus (A.D. 25), the former of whom was a Neapolitan by birth.

After the fall of the Roman empire, Neapolis suffered severely during the Gothic wars. Having espoused the Gothic cause in the year 536, it was taken, after a protracted siege, by Belisarius, who diverted the water of a subterranean aqueduct, marched into the city through it, and put many of the inhabitants to the sword. In 542 Totila besieged it and compelled it to surrender, but after being recovered by Narses, it long remained a dependency of the exarchate of Ravenna, under the immediate government of a duke, appointed by the East Roman emperors. When the Lombards pushed their conquests in the south, the limits of the Neapolitan duchy were considerably narrowed. In the beginning of the 8th century, at the time of the iconoclastic controversy, the Neapolitans, encouraged by Pope Gregory III., threw off their allegiance to the Eastern emperors, and established a republican form of government under a duke of their own appointment. Under this régime Neapolis retained independence for nearly 400 years, though constantly struggling against the powerful Lombard dukes of Benevento. The Normans, in their turn, gradually superseded all powers in the south of Italy, and checked the Saracens in their advances through Apulia.

From that date the history of Naples becomes that of a kingdom, sometimes separate, sometimes merged with the kingdom of Sicily in that of the Two Sicilies. The city of Naples henceforth formed the metropolis of the kingdom to which it gave its name. (See NAPLES, KINGDOM OF.)

BIBLIOGRAPHY.—R. T. Günther, *Earth Movements in the Bay of Naples* (Oxford, 1905); Rolfe and Ingleby, *Naples in 1888* (London, 1888); Black, *Naples in the Nineties* (1897); Arthur Norway, *Naples, Past and Present* (London, 1901).

NAPLES, BANK OF, is an autonomous, public utility, non-profit earping foundation, incorporated under a charter granted in 1866. Its origins date back to 1539 when two public-spirited Neapolitans, Aurelio Paparo and Leonardo di Palma, founded in their city a first bank with a capital of 4,000 ducats for granting loans on pledge and without or at a very low rate of interest to free the poorer classes from the evils of usury.

The institution rapidly developed, and survived all the vicissitudes of the kingdom of Naples. After the annexation of Naples to the kingdom of Italy the *Banco di Napoli* remained a bank of issue. Regional interests and the still strong traditions of regional independence maintained this situation until May 6, 1926, when the *Banca d'Italia* became the sole bank of issue.

The *Banco di Napoli* is a foundation organized as a trust, administered by a Board whose members are nominated by the Government, by the province and municipality of Naples, and by the organs representing the commercial activities of the province. Its officers have the status of public officials. Its capital and reserves stood in Dec. 1927 at 1,251.7 million lire. It acts as a savings bank, an agricultural credit bank, and a pledge bank for the southern provinces, and discharges the services connected with emigrant remittances from abroad, for which purpose it has agencies in New York and Chicago. Part of its profits are assigned to purposes of public utility and charity, the bulk going to increase its reserves.

By a process of amalgamation it has absorbed the agricultural credit institutes of the Southern provinces and is now the most powerful instrument for the progress of South Italian agriculture and one of the most effective agencies for economic development. (O. R. A.)

NAPLES, KINGDOM OF, the name conventionally given to the kingdom of Sicily on the Italian mainland (Sicily beyond the Faro), to distinguish it from that of Sicily proper (Sicily on this side of the Faro, i.e., Messina).

The leaders of the Norman house of Hauteville, Robert Guiscard and Richard of Aversa, in 1059 did homage to Pope Nicholas II. (q.v.) for all the conquests they made both in the island and upon the mainland. In 1130 Roger de Hauteville (Roger II. as "great count" of Sicily) assumed the style of king as Roger I. In this way the south of Italy, together with the island of Sicily, was converted into one political body.

The Hohenstaufen.—After the death of Tancred, son of William II., the emperor Henry VI., of the house of Hohenstaufen, who by his marriage with Constance or Costanza d'Altavilla, daughter of Roger I. (d. 1154), laid claims to the kingdoms of Naples and Sicily, descended into Italy in 1194. He easily conquered both the mainland and the island, but died in 1197. Costanza then had her son, Frederick (b. 1194) proclaimed king, and obtained the support of the Holy See on condition that the kingdom should be once more recognized as a fief of the Church. The Hohenstaufen kings afterwards refused to admit this claim; thus provoking the persistent hostility of the popes and many foreign invasions. Costanza died in 1198, leaving Pope Innocent III. regent and tutor to her son. In 1209 Frederick married Costanza, daughter of the king of Aragon, with whose help he succeeded in reducing a large part of Sicily to obedience. Two years later he was elected king of the Romans, and in 1220 he was crowned emperor in Rome by Pope Honorius III., but continued to reside in Sicily. In 1227 Gregory IX. excommunicated him because he delayed the crusade which he had promised to undertake. Frederick sailed for Palestine the following year and on his return defeated the army which the pope had sent into Neapolitan territory, peace being made at San Germano in 1230 and the excommunication withdrawn. In 1231 he issued the celebrated Constitutions of the Sicilian kingdom at the parliament of Melfi. He died in 1250.

His son Conrad IV. succeeded to the empire, while to his illegitimate son Manfred he left the principality of Taranto and the regency of the southern kingdom. Conrad died in 1254, leaving an infant son, Conradin (b. 1252), and Manfred was appointed vicar-general during the latter's minority. In 1258, on a rumour of Conradin's death, Manfred was offered and accepted the crown of Naples and Sicily. The rumour was false, but he retained the crown, promising to leave the kingdom to Conradin at his death and to defend his rights.

Angevin and Aragonese.—In 1265 Clement IV., wishing to rid himself of the Hohenstaufen, induced Charles of Anjou, brother of Louis IX. of France, to come to Italy. Agreeing to accept the kingdom of the Two Sicilies as a fief of the Church, Charles, in 1266, marched southward with the privileges of a crusader (see CHARLES I., king of Naples and Sicily). Manfred was defeated and killed at Benevento, and Charles was soon master of almost the whole kingdom.

In Sicily, however, Charles's government soon made itself odious by its exactions and the insolence and cruelty of the king's French officials and favourites. The malcontents were led by the Salernitan noble Giovanni da Procida, who had induced Peter III. of Aragon, husband of Manfred's daughter Costanza, to make good his shadowy claims to the crown of Sicily. On Easter day 1282, just as Charles was preparing an expedition to the East, the popular rising known as the Sicilian Vespers broke out at Palermo and resulted in the massacre of nearly all the French in the island. Peter reached Palermo in September. Pope Martin IV. proclaimed a crusade against the Aragonese, and the war continued for many years. The Sicilian fleet under Ruggiero di Lauria defeated that of the Angevins at Malta in 1283, and in 1284 in the Bay of Naples. Charles I. died in 1286; his heir, Charles the Lamé, being a prisoner, was not crowned until two years later. (See CHARLES II., king of Naples and Sicily, and FREDERICK III., king of Sicily.)

Charles II. died in 1309 and was succeeded by his second son Robert, who became leader of the Guelphs in Italy. War between

Naples and Sicily broke out once more, when Frederick allied himself with the emperor Henry VII. on his descent into Italy and proclaimed his own son Peter heir to the throne. Robert died in 1342; he had been a capable ruler, a scholar, and a friend of Petrarch, but his authority was limited by the rights of a turbulent and rebellious baronage (see ROBERT, king of Naples). He was succeeded by his granddaughter Joanna, wife of Andrew of Hungary, who was assassinated in 1345, not without suspicion of Joanna's complicity. Andrew's brother Louis, king of Hungary, attempted to make good his claims on Naples and avenge the murder of Andrew; but as Pope Clement refused to recognize his claims he went back to Hungary in 1348 and Joanna and her second husband Louis of Taranto were crowned at Naples by the pope's legate in 1352, but Niccolò Acciaiuoli, the seneschal, became the real master of the kingdom. Joanna nominated Louis of Anjou her heir, but while the latter was recognized by the anti-pope Clement VII., Pope Urban VI. declared Charles of Durazzo (great-grandson of Charles II.) king of Sicily *al di quò del Faro* (i.e. of Naples). Charles conquered the kingdom and took Joanna prisoner in 1381, and had her murdered the following year. Louis failed to drive out Charles, and died in 1384. A period of anarchy followed during the reigns of Charles III. and his son Ladislas, and on the latter's death in 1414 he was succeeded by his sister Joanna II. (q.v.), during whose reign the kingdom sank to the lowest depths of degradation. Louis died in 1434 and Joanna in 1435. Alphonso was recognized as king of Naples by Pope Eugene IV. in 1443.

Under Alphonso, surnamed "the Magnanimous," Sicily was once more united to Naples and a new era was inaugurated, for the king was at once a brilliant ruler, a scholar, and a patron of letters. He died in 1458, leaving Naples to his illegitimate son Ferdinand I. (Don Ferrante) (q.v.), and Sicily, Sardinia, and Aragon to his brother John. Ferdinand died in 1494 and was succeeded by Alphonso. In the September of the following year Charles VIII. of France entered Italy and conquered the Neapolitan kingdom without much difficulty. Alphonso abdicated, and his son Ferrandino and his brother Frederick withdrew to Ischia. But Ferrandino, with the help of Ferdinand II. of Spain, was able later to reoccupy his dominions. He died much regretted in 1496 and was succeeded by Frederick. The country was torn by civil war and brigandage, and the French continued to press their claims; until, with Gonzalo de Cordoba's victory on the Garigliano in Dec. 1502, the whole kingdom was in Spanish hands.

Spanish Rule.—On Ferdinand's death in 1516, the Habsburg Charles became king of Spain, and three years later was elected emperor as Charles V.; in 1522 he appointed John de Lanoy viceroy of Naples, which became henceforth an integral part of the Spanish dominions. Spanish rule presently provoked several rebellions. On July 7, 1647, tumults occurred at Naples in consequence of a new fruit tax, and the viceroy, Count d'Arcos, was forced to take refuge in the Castelnuovo. The populace, led by an Amalfi fisherman, known as Masaniello (q.v.), obtained arms, erected barricades, and, while professing loyalty to the king of Spain, demanded the removal of the oppressive taxes and murdered many of the nobles. D'Arcos came to terms with Masaniello; but in spite of this, and of the subsequent assassination of Masaniello, the disturbances continued.

In 1670 disorders broke out at Messina, which developed into an anti-Spanish movement; and while the inhabitants called in the French, the Spaniards, who could not crush the rising, called in the Dutch. In 1707 an Austrian army conquered the kingdom and Spanish rule came to an end.

The Bourbons.—In Sicily the Spaniards held their own till the peace of Utrecht, in 1713, when the island was given over to Duke Victor Amadeus of Savoy, who assumed the title of king. In 1718 he had to hand back his new possession to Spain, which, in 1720, surrendered it to Austria and gave Sardinia to Victor Amadeus. In 1733 the treaty of the Escurial between France, Spain, and Savoy against Austria was signed. Don Carlos of Bourbon, son of Philip V. of Spain, easily conquered both Naples and Sicily, and in 1738 he was recognized as king of the Two Sicilies, Spain renouncing all her claims. Charles was well re-

ceived and, with the Tuscan Bernardo Tanucci as his minister, introduced many useful reforms. In 1759 Charles III., having succeeded to the Spanish crown, abdicated that of the Two Sicilies in favour of his 8-year-old son Ferdinand, who became Ferdinand IV. of Naples and III. of Sicily, with a regency under Tanucci. The regency ended in 1767, and the following year Ferdinand married the masterful and ambitious Maria Carolina, daughter of the empress Maria Theresa. With the help of John Acton, an Englishman whom she made minister in the place of Tanucci, she secured a *rapprochement* with England and Austria.

On the outbreak of the French Revolution the king and queen were not at first hostile to the new movement; but in 1793 they joined the first coalition against France, instituting severe persecutions against all who were remotely suspected of French sympathies. Republicanism, however, gained ground, especially among the aristocracy. In 1798, during Napoleon's absence in Egypt and after Nelson's victory at Aboukir, Maria Carolina induced Ferdinand to go to war with France. The French marched on Naples, but not until Jan. 20, 1799, were the invaders masters of the city. On the 23rd the Parthenopaean republic was proclaimed. The Republicans were men of culture and high character, but doctrinaire and impractical, and they knew very little of the lower classes of their own country. Meanwhile the court at Palermo sent Cardinal Fabrizio Ruffo to Calabria, to organize a counter-revolution. He succeeded beyond expectation, and with his "Christian army of the Holy Faith" (*Esercito Cristiano della Santa Fede*), consisting of brigands, convicts, peasants and some soldiers, advanced on the capital, whence the French, save for a small force under Méjean, withdrew. On June 13 Ruffo and his hordes reached Naples and, after a desperate battle at the Ponte della Maddalena, entered the city. The French in Castel Sant' Elmo and the Republicans in Castelnuovo and Castel dell' Uovo still held out and finally an armistice was concluded and a capitulation agreed upon, whereby the castles were to be evacuated and the garrisons free to remain in Naples unmolested or to sail for Toulon.

Nelson at Naples.—On June 24 Nelson arrived with his fleet, and on hearing of the capitulation refused to recognize it save in so far as it concerned the French. Ruffo indignantly declared that the treaty had been signed, not only by himself but by the Russian and Turkish commandants and by the British captain, Foote. On the 26th Nelson changed his attitude and informed the cardinal that he would do nothing to break the armistice; while Captains Bell and Troubridge wrote that they had Nelson's authority to state that the latter would not oppose the embarkation of the Republicans, who thereupon embarked on the vessels prepared for them. But on the 28th Nelson, acting on despatches from the court (in reply to his own), held up the vessels and many of the Republicans were arrested. Caracciolo, who commanded the Republican Fleet, was tried by court-martial on board Nelson's flagship, condemned to death, and hanged at the yard arm, (see CARACCILO and NELSON).

On July 8 King Ferdinand arrived from Palermo and the State trials resulted in hundreds of persons being executed, including some of the best men in the country, such as the philosopher Mario Pagano, the scientist Cirillo, Massa, the defender of Castel dell' Uovo, and Ettore Caraffa, the defender of Pescara. After the peace of Amiens in 1802 the court returned to Naples, where it was well received. But when the European war broke out again in the following year King Ferdinand played a double game, appearing to accede to Napoleon's demands while negotiating with Britain. After Austerlitz, Napoleon declared that "the Bourbon dynasty had ceased to reign" and sent an army under his brother Joseph to occupy the kingdom.

Joseph Bonaparte and Murat.—Ferdinand and Maria Carolina fled to Palermo in 1805; in Feb. 1806 Joseph Bonaparte entered Naples as king. A cultivated, well-meaning, not very intelligent man, he introduced many useful reforms and abolished feudalism, but the taxes and forced contributions proved very burdensome. Joseph's authority did not exist throughout a large part of the kingdom, where royalist risings, led by brigand chiefs, maintained a state of anarchy, and a British force, under Sir John

Stuart, defeated the French at Maida in Calabria (July 6, 1806).

In 1808 Napoleon conferred the crown of Spain on Joseph and appointed Joachim Murat king of Naples. Murat continued Joseph's reforms and reorganized the army; and although he introduced the French codes and conferred many appointments and estates on Frenchmen, his administration was more or less native and favoured the abler Neapolitans. The king gained many sympathies; he gradually became estranged from Napoleon and secretly opened negotiations with Austria and Great Britain. In Jan. 1814 he signed a treaty with Austria, and the following month proclaimed his separation from Napoleon. But when Napoleon escaped from Elba, Murat suddenly returned to the allegiance of his old chief, marched into northern Italy, and from Rimini issued his famous proclamation in favour of Italian independence (March 30, 1815). He was subsequently defeated by the Austrians several times and on May 18 sailed from Naples for France (see MURAT, JOACHIM). On the 23rd the Austrians entered Naples to restore Bourbon rule.

The Restoration.—Ferdinand and Maria Carolina had continued to reign in Sicily, where the court's extravagance and the odious Neapolitan system of police espionage rendered their presence a burden instead of a blessing to the island. A bitter conflict broke out between the court and the parliament, and the British minister, Lord William Bentinck, forced Ferdinand to resign his authority and appoint his son regent and introduced many valuable reforms. In 1812 a constitution on British lines was introduced, and the queen, who was perpetually intriguing against Bentinck, was exiled. Bentinck, whose memory is still cherished in the island, departed in 1814. Ferdinand dissolved parliament in May 1815, after concluding a treaty with Austria for the recovery of his mainland dominions by means of an Austrian army. On June 9 Ferdinand re-entered Naples and bound himself in a second treaty with Austria not to introduce a constitutional government. At first he abstained from persecution and received many of Murat's old officers into his army. In Oct. 1815 Murat, believing that he still had a strong party in the kingdom, landed with a few companions at Pizzo di Calabria, but was immediately captured by the police and the peasantry, court-martialled, and shot.

Ferdinand proclaimed himself king of the Two Sicilies at the congress of Vienna, incorporating Naples and Sicily into one state, and abolished the Sicilian constitution (Dec. 1816). In 1818 he concluded a Concordat with the Church, by which the latter renounced its suzerainty over the kingdom, but was given control over education, the censorship, and many other privileges. But there was much disaffection throughout the country, and the Carbonarist lodges had made much progress, especially in the army (see CARBONARI). In July 1820 a military mutiny broke out at Caserta, the mutineers demanding a Spanish constitution although professing loyalty to the king. Ferdinand, feeling himself helpless to resist, acceded to the demand. The new government's first difficulty was Sicily, where the people had risen in rebellion demanding their own charter of 1812, and although the Neapolitan troops quelled the outbreak with much bloodshed the division proved fatal to the prospects of liberty.

This outbreak seriously alarmed the Powers responsible for the preservation of the peace in Europe. At the congress of Troppau (Oct. 1820) the famous protocol was issued affirming the right of collective "Europe" to interfere to crush dangerous internal revolutions. Both France and Great Britain protested against this dangerous principle; but by general consent King Ferdinand was invited to attend the adjourned congress, fixed to meet at Laibach in the spring of the following year. Under the new constitution the permission of parliament was necessary before the king could leave Neapolitan territory. This was weakly granted, after Ferdinand had sworn the most solemn oaths to maintain the constitution. He was scarcely beyond the frontiers, however, before he repudiated his engagements, as exacted by force. The powers authorized Austria to march an army into Naples to restore the autocratic monarchy. General Pepe commander of the Constitutional forces, was sent to the frontier at the head of 8,000 men, but was completely defeated by the

Austrians at Rieti on March 7. On the 23rd the Austrians entered Naples, followed soon afterwards by the king. Every vestige of freedom was suppressed, and the inevitable State trials instituted with the usual harvest of executions and imprisonment. Pepe saved himself by flight. (See FERDINAND IV., king of Naples.)

Ferdinand died in 1825 and was succeeded by his son Francis I., an unbridled libertine, under whom the corruption of the administration assumed unheard-of proportions. (See FRANCIS I., king of the Two Sicilies.) He died in 1830 and was succeeded by his son, Ferdinand II., who at first awoke hopes that the conditions of the country would be improved; but on the death of his first wife, Cristina of Savoy, he married Maria Theresa of Austria, who encouraged him in his reactionary tendencies and brought him closer to Austria. The desire for a constitution was by no means dead, and the survivors of the old Carbonari gathered round Carlo Poerio, while the *Giovane Italia* society (independent of Mazzini) promoted a few sporadic outbreaks easily crushed. The following year the Venetian brothers Bandiera, acting in concert with Mazzini, landed in Calabria, believing the whole country to be in a state of revolt; they met with little local support and were quickly captured and shot, but their deaths aroused much sympathy, and the whole episode was highly significant as being the first attempt made by Italians from other parts of the country to promote revolution in the south.

Revolution of 1848.—On Jan. 12, 1848, a revolution under the leadership of Ruggiero Settimo broke out in Sicily. These events were followed by demonstrations at Naples, and on Jan. 28 the king granted the constitution. The popular demand was now that Naples should assist the Lombards in their revolt against Austria, for a feeling of Italian solidarity was growing up. Ferdinand declared war against Austria (April 7, 1848); and a Neapolitan army under General Pepe marched towards Lombardy in May, while the fleet sailed for Venice. But a dispute between the king and the parliament concerning the form of the royal oath having arisen, a group of demagogues with criminal folly provoked disturbances and erected barricades (May 14). The king refused to open parliament unless the barricades were removed. A few shots were fired on the 15th, the Swiss regiments stormed the barricades and street fighting lasted all day. By the evening the Swiss and the royalists were masters of the situation. A new ministry under Prince Cariati was appointed. Parliament was dissolved, the National Guard disbanded and the army recalled from the Po.

In Sicily the revolutionists were bitterly hostile to the Neapolitans. The Sicilian assembly met in March 1848, and Settimo in his inaugural speech declared that the Bourbon dynasty had ceased to reign and that Sicily united her destinies to those of Italy; Settimo was elected president of the Government. After the Austrian victories Ferdinand sent a Neapolitan army under Carlo Filangieri (*q.v.*) to subjugate the island. The troops landed at Messina, whose citadel had been held by the royalists throughout, and after three days' desperate fighting the city itself was captured and sacked. Filangieri marched forward, committing many atrocities. In April he reached Palermo while the fleet appeared in the bay, and tumults having broken out within the city the Government surrendered on terms which granted amnesty for all except Settimo and 42 others.

For a few months after the dissolution of the Neapolitan parliament the Government abstained from persecution, but with the crushing of the Sicilian revolution its hands were free; and when the commission on the affair of May 15 had completed its labours thousands of respectable citizens were thrown into prison, such as L. Settembrini, Carlo Poerio, and Silvio Spaventa. The abominable conditions of the prisons in which the best men of the kingdom were immured were made known to the world by the famous letters of W. E. Gladstone, which branded the Bourbon regime as "the negation of God erected into a system of government." In 1857 Carlo Pisacane, an ex-Neapolitan officer who had taken part in the defence of Rome, fitted out an expedition, with Mazzini's approval, from Genoa, and landed at Sapri in Calabria; but the local police assisted by the peasantry attacked the band, killing many, including Pisacane himself, and

capturing most of the rest. The following year, at the instance of Great Britain and France, Ferdinand commuted the sentences of some of the political prisoners to exile. (See FERDINAND II., king of the Two Sicilies.)

In May 1859 Ferdinand died and was succeeded by his son, Francis II. (*q.v.*). Victor Emmanuel, king of Sardinia, wrote to him proposing an alliance for the division of Italy, but Francis refused. In June part of the Swiss Guard mutinied and were shot down; and this affair resulted in the disbanding of the whole force—the last support of the autocracy. Various proposals were made for an alliance with Sardinia, but Francis rejected them and indeed began to negotiate with Austria.

Garibaldi.—In the meantime events in Sicily were reaching a crisis destined to subvert the Bourbon dynasty. Mazzini's emissaries, F. Crispi (*q.v.*) and R. Pilo, had been trying to organize a rising in favour of Italian unity and, although they merely succeeded in raising a few armed bands, they persuaded Garibaldi (*q.v.*) that the revolution, which he knew to be imminent, had broken out. Garibaldi, whose hesitation had been overcome, embarked on May 5, 1860, at Quarto, near Genoa, with 1,000 picked followers on board two steamers, and sailed for Sicily. On the 11th the expedition reached Marsala and landed without opposition. Garibaldi was somewhat coldly received by the astonished population; but he set forth at once for Salemi, where he issued a proclamation assuming the dictatorship of Sicily in the name of Victor Emmanuel, with Crispi as secretary of state. On the 15th he attacked and defeated 3,000 of the enemy under General Landi at Calatafimi; the news of this brilliant victory revived the revolutionary agitation throughout the island, and Garibaldi was joined by Pilo and his bands. By a cleverly devised ruse he avoided General Colonna's force, which expected him on the Monreale road, and entering Palermo from Misilmeri received an enthusiastic welcome. After three days' street fighting the Bourbonist commander, General Lanza, not knowing that the Garibaldians had scarcely a cartridge left, asked for and obtained a 24 hours' armistice (May 30). Garibaldi went on board the British flagship to confer with the Neapolitan generals Letizia and Chrétien; then he informed the citizens by means of a proclamation of what he had done, and declared that he would renew hostilities on the expiration of the armistice. Although unarmed, the people rallied to him as one man, and Lanza became so alarmed that he asked for an unconditional extension of the armistice, which Garibaldi granted; 15,000 Bourbon troops embarked for Naples on June 7, leaving the revolutionists masters of the situation. The Sardinian Admiral Persano's salute of 19 guns on the occasion of Garibaldi's official call constituted a practical recognition of his dictatorship by the Sardinian (Piedmontese) Government. In July further reinforcements of volunteers under Cosenz and Medici, assisted by Cavour, arrived at Palermo with a good supply of arms furnished by subscription in northern Italy. Garibaldi's forces were now raised to 12,000 men, besides the Sicilian *squadre*. Cavour's attempt to bring about the annexation of Sicily to Sardinia failed, for Garibaldi wished to use the island as a basis for an invasion of the mainland. When the Garibaldians advanced eastward they encountered a force of 4,000 of the enemy under Colonel Bosco at Milazzo; on July 20 a desperate battle took place, resulting in a hard-won Garibaldian victory. The Neapolitan Government then decided on the evacuation of the whole of Sicily except the citadel of Messina, which did not surrender until the next year.

The news of Garibaldi's astonishing successes entirely changed the situation in the capital, and on June 25, 1860, the king granted a constitution, and appointed A. Spinelli prime minister. Disorders having taken place between Liberals and reactionaries, Liborio Romano was made minister of police in the place of Aiossa. The king appealed to Great Britain and France to prevent Garibaldi crossing the Straits of Messina, and only just failed (for this episode see under LACAITA, SIR JAMES). On Aug. 19 Garibaldi crossed with 4,500 men and took Reggio by storm. He was soon joined by the rest of his troops, 15,000 in all, the Neapolitan army collapsed before Garibaldi's advance, and the people rose in his favour almost everywhere. On Sept. 6 the

king and queen sailed for Gaeta; on the 7th Garibaldi entered Naples alone, although the city was still full of soldiers, and was received with delirious enthusiasm; on the 11th a part of the royalists capitulated and the rest retired on Capua. Cavour now decided that Sardinia must take part in the liberation of southern Italy, for he feared that Garibaldi's followers might induce him to proclaim the republic and attack Rome, which would have provoked French intervention; consequently a Piedmontese army occupied the Marche and Umbria and entered Neapolitan territory with Victor Emmanuel at its head. On Oct. 1 and 2, 1860, a battle was fought on the Volturno and the Garibaldians, although inferior in numbers, were victorious. On the 26th he met Victor Emmanuel at Teano and hailed him king of Italy and subsequently handed over his conquests to him. On Nov. 3 a plebiscite was taken, which resulted in an overwhelming majority in favour of union with Sardinia under Victor Emmanuel. Garibaldi departed for his island home at Caprera, while L. C. Farini was appointed viceroy of Naples and M. Cordero viceroy of Sicily. The last remnant of the Bourbon army was concentrated at Gaeta, the siege of which was begun by Cialdini on Nov. 5; on Jan. 10, 1861, the French fleet, which Napoleon III. had sent to Gaeta to delay the inevitable fall of the dynasty, was withdrawn at the instance of Great Britain; the fortress surrendered on Feb. 13 and the royal family departed by sea. The citadel of Messina capitulated a month later and Civitella del Tronto on March 21. On Feb. 18 the first Italian parliament met at Turin and proclaimed Victor Emmanuel king of Italy. Thus Naples and Sicily ceased to be a separate political entity and were absorbed into the united Italian kingdom.

NAPOLEON I. (1769–1821), emperor of the French. Napoleon Bonaparte was born at Ajaccio on Aug. 15, 1769, the year following the reunion of Corsica with France. His father, Charles Buonaparte—it was not until after 1796 that the spelling Bonaparte was adopted—came of a good family which had been established in the island since the 16th century. The family origins may perhaps be traced to Tuscany, an Italian province, the relations of which with Corsica had always been close. Napoleon himself, in later years, scoffed at the exaggerated tales invented by flatterers and courtiers, of the lordly status formerly held by the family at Treviso and Bologna. Yet his father was undoubtedly of noble birth, and was the delegate of the Corsican nobility at Paris. Charles Buonaparte married Laetitia Ramolino, a woman of strong character and great personal beauty. He was a lawyer by profession and brought up a large family in difficult times. After the Corsicans had, several times, revolted against their Genoese masters, the republic of Genoa, despairing of ever bringing the rebels to submission, ceded its rights to France, against which the Corsicans, led by Paoli (*q.v.*) at first attempted resistance. Charles Buonaparte joined Paoli's party. He even joined him in his campaign, taking with him his wife and children,

lest they should be seized as hostages by the French. When Paoli was beaten and had to fly Charles Buonaparte became reconciled to French rule and benefited by the protection of M. de Marbeuf, the governor, to whom he was able to make himself useful. In 1779, sent on a mission to Versailles, he took with him his second son, Napoleon, for whom M. de Marbeuf had obtained a bursary at the military academy at Brienne.

EARLY LIFE

These facts enable us to understand the character of Napoleon. He was born a Frenchman, of a family which, unwilling at first to become French, afterwards unreservedly accepted the *fait accompli*. From the age of ten he was educated with other boys of his own class by French people according to French ideas. Though we must make due allowance for heredity, family influence, and the impressions of early childhood, it is an exaggeration to explain Napoleon, as historians since Stendhal have been too much inclined to do, entirely in the light of his Corsican and Tuscan origin, and to see in him the incarnation of a *condottiere*, or of a 14th century Italian city despot, a modern Castruccio Castracani. It is more important to bear in mind that young Bonaparte, born in an island which had only just become part of France, shared neither the traditions nor the prejudices of his new country.

In 1789, at the age of 20, he came into the Revolution with an open mind, feeling neither like nor dislike for many things which other Frenchmen either regretted or frankly detested. If he remained Corsican in temperament he was, by virtue of the instruction he had received, and the books he had read, pre-eminently a man of the 18th century. His occasional early philosophical writings leave no doubt as to this side of his character, which is also illustrated by the life-long habit of epigrammatic, well-turned, often paradoxical expression, a trait which he had in common with Chamfort and Rivarol; witness his celebrated definition of love as "*une sottise faite à deux*." Further, having lost his father in 1785, and having been designated by him as the head of the family, although he was the second and Joseph the eldest son, he had known poverty and the responsibility of helping to provide for his mother, brothers and sisters. Success was more necessary to him than to others, and the upheaval of 1789 favoured the ambitious.

We must realize therefore that he entered the Revolution in rather an unusual frame of mind, occasionally ardent, joining the Jacobins without hesitation, but also capable of coolly judging events as when on June 20, at the capture of the Tuileries, he was moved to scorn by the weakness of Louis XVI. We must also remember that, having begun his studies at the cadet school at Brienne, he completed them at the *Ecole Militaire* in Paris, where (1784-5) he received a solid grounding in the work of an artilleryman and an officer. It would be wrong to look on him as a kind of self-taught genius, a god of war, who might be said to have discovered, taught, and even created strategy and tactics.

The Artillery Officer.—He himself acknowledged, modestly and loyally, his debt to his teachers. He had studied the treatises of Bourcet and of Guibert, who had evolved from modern armaments new principles and methods of warfare. As a sub-lieutenant at Auxonne, after leaving the *Ecole Militaire*, he received at first hand instruction from baron du Teil, brother of the author of a remarkably advanced work on the use of modern artillery. He profited by the instruction, and always spoke of it with appreciation. However gifted a man may be, he still needs inspiration and counsel, and learns more from his predecessors than he himself passes on to his contemporaries and to posterity. The genius of Napoleon was not least evident in the way in which he made use of the instruction which he received. Curiously enough, Guibert in his *Système de guerre moderne* had predicted that a great man would arise to put into practice the military theories which were then taking shape. These facts, which place Napoleon in his proper intellectual environment, seem to the writer to throw more light on his mind and his character than would countless anecdotes of his childhood and schooldays, such as that at Brienne he was nicknamed *Paille au nez* by his companions because of the

way in which he pronounced *Napolione*.

Between his spells of garrison duty at Valence and at Auxonne as a young artillery officer, a part of his early career of which little is known was passed in the leave which he spent on more than one occasion in Corsica, where the somewhat complicated affairs of his family demanded his presence. At Ajaccio in Sept. 1789, he found his elder brother Joseph deep in the affairs of the democratic party which had inevitably, with the progress of the Revolution, become the party of France. Paoli, who had at first thought that events in France would bring about Corsican independence, had soon been disillusioned, Jacobinism being essentially a unifying and centralising force. He inclined therefore to the counter-revolution and entered the opposite camp.

Napoleon, promoted lieutenant in 1791 on the reorganization of the artillery, was stationed for another three months at Valence, where he continued his studies, and even wrote an essay on a subject set for competition by the academy of Lyons: "What are the principles and institutions most likely to bring about the greatest happiness of mankind?" He treated the subject in the style and according to the principles of Jean Jacques Rousseau. When, years afterwards, Talleyrand showed him the essay, he threw it into the fire.

He was again in Corsica from Sept. 1791 to May 1792. Feeling ran high in the island, as a result of the disestablishment of the Catholic Church. He plunged into political intrigue, outstayed his leave, and became liable to the penalties in force against deserters and émigrés. On April 20, 1792, however, the legislative assembly had declared war on Austria. Officers were needed. Instead of undergoing any penalty, Bonaparte, whose zeal for the Revolution was well known, was made a captain. In this capacity he remained in Paris for several months, and witnessed the great events of the Revolution. After the September massacres, he went to Ajaccio to take home his sister Elisa from the convent of Saint Cyr which had just been closed. This was his last visit to his native country. The break with Paoli was now complete. Bonaparte was on the side of the "*patriotes*," while the old champion of independence was appealing to the English against the Republic, One and Indivisible. Paoli was victorious. Bonaparte and his family, now entirely ruined, had to fly from the island and take refuge in France. This was the termination of what we may call his "insular" period. As he himself said afterwards, once he had left Ajaccio, more important affairs left him little time to think of Corsica and Paoli.

Early Military Opportunities.—In Sept. 1793, Napoleon Bonaparte was still unknown to the world which was to ring with his name. Amazed himself at his extraordinary career, and the incredible swiftness of his rise to power, he said in Saint Helena to Las Cases, "Centuries will pass before the unique combination of events which led to my career recur in the case of another." Favourable circumstances were also required to bring the young artillery officer to the front, and these were not lacking. The republic, which had challenged half Europe, had to face foreign and civil war, under conditions of anarchy. Bonaparte was a Jacobin, with a great reputation as an artillery officer. At Beaucaire, on his way to Paris, he had written a pamphlet, the *Souper de Beaucaire*, in which he had refuted the arguments of three Southern federalists or counter-revolutionaries. It is probable that it reflects a conversation which actually took place in an inn of the little town beside the Rhone. Its publication attested the patriotism of its author. The good word of Robespierre's brother and of Napoleon's compatriot, the deputy Salicetti, were also of assistance. At this juncture it was necessary to recapture Toulon, the inhabitants of which had rebelled against the Convention and called in the assistance of an English squadron. An able officer of artillery was required to direct the siege operations. Bonaparte was chosen.

There has since grown up the legend of "the great Napoleon at the siege of Toulon," though the part which he really played was essentially that of a technical expert. He found in command General Carteaux, formerly an artist, who was too ignorant even to understand that to take Toulon he must capture the position which commanded the roadstead. Things were no better under

his successor, Doppet, and until the arrival of General Dugommier, a soldier of greater experience, who, together with Gasparin, the people's commissary, recognized the knowledge and good sense of the young artillery officer.

On the fall of Toulon in Dec. 1793, Napoleon was promoted general of brigade, and in Feb. 1794 he was given the command of the artillery of the army of Italy. These were still subordinate positions, offering little opportunity for prominence. He spent the next few months—the period of the Terror—in inspecting fortifications and was even for a time “suspect” for having reconstructed an old fort at Marseilles, a town which had also risen against the Convention. He had rejoined the army of Italy, when fresh disaster seemed imminent. After the 9th Thermidor, his relations with the Jacobins became compromising. Accused of having disclosed certain plans to the younger Robespierre, he was arrested, but, in default of evidence, was released on Carnot's instructions. Nevertheless his position at this juncture was extremely precarious. Under the nerveless leadership of Schérer, he had no opportunity of distinguishing himself in the Italian campaign except at Saorgio and on the Roja. He was marking time, in fact. Like a true soldier he detested the campaign in la Vendée, and he refused the command of an infantry brigade which was to be sent against the Western royalists. Aubry, the minister of war, removed him from the active list in consequence.

Reverses.—He now experienced real poverty, and had to sell his books and his watch. He thought of taking service with the sultan to re-organize the Turkish army. Madame Tallien, wife of the member of the Convention, whom he met at this time, interested herself in him and made his peace with the authorities. When Kellermann lost the lines of the Apennines it was remembered that Bonaparte knew Italy, he was taken into consultation, and joined the topographical service of the army.

At this time, in the autumn of 1795, Hoche, Marceau and Jourbert were already famous; Bonaparte was still unknown. It looked almost as if fortune were definitely against him. The only thing which he had brought back from his campaigns was the itch and, probably, the malaria, which made him very ill. He was obliged to shave his head, which was later on to bring him the nickname of “*le petit tondu*.” Small in stature, thin, yellow-faced, badly dressed, his person was unimposing and no one would have seen in him the future emperor of the French.

The Insurrection of 1795.—It needed a day of revolution and of civil war to bring him into prominence, by giving him the chance to do the Republican Government a service, the vital service of saving the Republic. In the autumn of 1795 the majority of the people of Paris were chafing against dear food, *assignats* and never-ending war. The Convention, by declaring for a constitution designed to keep its own members in power, provoked an insurrection, which, owing to the weakness of General Menou, very nearly succeeded. The Convention then placed the deputy Barras in command of the home forces. He, having known and learnt to value Bonaparte at the siege of Toulon, asked for, and obtained, his appointment as second in command. The young general at once assumed complete control, issued rapid orders, forestalled the insurgents who were about to capture the artillery parked at Les Sablons, and shot them down in the rue Saint-Honoré, on the steps of the church of Saint-Roch. In less than a day he had subdued a serious royalist rising (13 *Vendémiaire*—Oct. 4, 1795). He had saved the republic and earned the nickname *Général Vendémiaire*.

ITALIAN AND EGYPTIAN CAMPAIGNS

Italy.—His first reward was the hand of Josephine, a beautiful Creole, widow of the viscount de Beauharnais, who had been guillotined during the Terror. Josephine, whose morals were none too strict, was living at this time mainly by her wits. The general was six years younger than she, but he seemed to be on the threshold of a brilliant career, and the marriage freed her from poverty. He had, in fact, as his second reward been appointed commander in chief of the Army of Italy. Like Josephine, the government of the Republic was at the end of its financial resources. At this moment, indeed, there was difficulty enough in

feeding the troops; it was hoped they would live on the conquered territory. At the beginning of March 1795 Bonaparte married Josephine. At the end of the month he arrived at his headquarters at Nice.

His army consisted of thirty thousand starving soldiers, in want of everything. He issued to them the famous proclamation:—“You are badly fed and all but naked. . . . I am about to lead you into the most fertile plains in the world. Before you are great cities and rich provinces; there we shall find honour, glory, and riches.” He entered Italy on April 10. His plan of campaign—the separation of the Piedmontese from the Austrians—was very simple; he executed it successfully after severe actions at Montenotte, Millesimo and Dego.

While he was conducting the campaign, he did not forget that he was a general of the Revolution, and issued to the Italian people proclamations which, while treating the Catholic religion with respect, spoke the language of liberty. The king of Sardinia took fright, and, on the advice of the Archbishop of Turin, sued for peace to an army “with neither artillery, cavalry, nor shoes to its feet.” The pope and the dukes of Parma, Modena and Tuscany were not long in following the example of Victor Amadeus. Great political schemes were taking shape in Bonaparte's mind, but first he had to beat the Austrians. This was, indeed, his first experience of large-scale operations. The crossing of the bridge of Lodi was a bold achievement which made his name known in a day all over France and indeed all over Europe. That day, by an old camp custom, his soldiers dubbed him corporal, and another nick-name, the “*petit caporal*,” stuck to him.

New Republics.—In May, some weeks after the setting out of his ragged army, he entered Milan in triumph. He could write to the directory: “The republic holds all Lombardy.” At that same moment he received from Paris orders which upset all his plans. Sure that his resignation would not be accepted, he sent it in, and, while waiting for the answer, harried the Austrians, whose generals “faithful to the old system of warfare, scattered their troops in small detachments before a man who practised mass-movement.” The further Bonaparte advanced with so small an army, the greater was the need for skill and boldness. At Arcola he suffered in his own person, by falling into a swamp. These “miracles of genius and courage” were crowned by the victory of Rivoli, followed by the preliminary negotiations of Leoben (April 18, 1797). “No other general could show such fourteen months.” He had forced Austria to sue for peace. He had founded the Cispadane, the Cisalpine, and the Ligurian republics, which brought a large part of Italy under the same *régime* as France, and preparations were begun for its annexation. He had been able to provide for his army by requisitioning; to conquer without costing the treasury anything, and had even sent money to Paris. Finally when the Republicans, having lost their majority in the Councils, were in need of help, Bonaparte, though he had cause for complaint against the directory, sent them his subordinate Augereau, for, the *coup de force* of Fructidor (Sept. 1797) directed against the royalists and the moderates. True, the royalists and moderates wanted peace, while Bonaparte agreed with the Jacobins, and aspired to secure France's “natural frontiers.”

He was able to congratulate himself on fulfilling both desires by the Treaty of Campo-Formio (Oct. 17, 1797). By it the emperor ceded to France both Belgium and the left bank of the Rhine. Glorious as it was, however, and in keeping with Revolutionary foreign policy, the treaty, far from ending the war, perpetuated it. To assure the permanence of these conquests the goodwill of England was necessary, and England was not in a position to give it; compulsion was therefore necessary. The whole story of Napoleon up to Waterloo turns on this. Henceforth he was to struggle against England, and in that struggle he was in the end to be vanquished.

England and Egypt.—The brusqueness of his manner, and still more his popularity with the masses made him an object of suspicion, in spite of the services which he had rendered the Republic. He, on his side, despised the corrupt government of the directory, “a government of lawyers,” whether Jacobin or moderate. He soon realised that their plans for an invasion of England

had no chance whatever of success. In any case he thought it prudent to quit France for a time. The East had always fascinated him. "Only in the East can one do great things," he said. Reading and reflection had convinced him that Egypt was one of the keys of the world. This idea had already emerged in the days of Louis XIV., and was taken up again during the 18th century wars between France and England; there too Napoleon had his fore-runners. He planned to strike at the power of England through Egypt and the route to India, and to stir the imagination of his own country-men. The directory accepted the scheme.

The Egyptian expedition was thus indirectly to be the means of forcing the British government to recognise the territorial acquisitions of the Revolution. The weakness of this plan, a weakness inherent in the whole struggle with England, was that France had no navy. Though Bonaparte, by a fortunate combination of circumstances, was able to land his army near Alexandria (July 1, 1798), Nelson, a month later (Aug. 1), destroyed the French fleet at Aboukir. From that moment the Egyptian expedition, instead of being "*le commencement d'une grande chose*" was merely an adventure. In vain Bonaparte executed a brilliant campaign, capturing Cairo, and subduing the country in three weeks. Of the great expedition nothing has endured but famous sayings, such as "Soldiers, from these pyramids forty centuries look down on you"; the Institute of Egyptology; the diffusion of the French language in the valley of the Nile; and, in Bonaparte's own case, a romantic touch of orientalism, symbolised by his faithful mamluke Roustan. Nevertheless, to carry through his great scheme, he undertook the conquest of Syria. Acre, under Admiral Sidney Smith, held out. "That man made me miss my destiny," he said later.

18th BRUMAIRE AND THE CONSULATE

The Coup d'État.—The expedition was, in fact, a failure. Bonaparte realized that there was nothing to be done in Egypt. At the same time came news which told him that there was work for him in France. The directory was in difficulties both at home and abroad. Disorder was rampant, finance and currency desperate, discontent everywhere. The Government, not knowing which way to turn, swayed one day to the Jacobins, the next to the moderates. In Germany the war continued, and in Italy the Republican armies suffered a series of reverses, and invasion was only checked with difficulty by Brune at Bergen, and by Masséna at Zürich. The restoration of the monarchy seemed inevitable. The republic could be saved only by a military leader. "I seek a sword," said Sieyès, one of the five directors, racking his brains for a general to whom he could confide the defence of the Republic. At that crucial moment Bonaparte decided to return. He went boldly on board a frigate, slipped through the English cruisers in the Mediterranean, and landed at Fréjus on Oct. 8, 1799. He was greeted with shouts of "Long live the republic." He was the man of the hour for all those who desired an end of anarchy but were opposed to the return of the Bourbons. Without him the Revolution was a lost cause. This consideration is essential to the understanding of the famous *coup d'état* of the 18 Brumaire (Nov. 9, 1799).

The *coup d'état* was organized, indeed, from within. Not only had Bonaparte accomplices among those in power, he had not even to offer or to impose himself; he was sought out. Baudin, a deputy from the Ardennes, and a staunch Republican, died of joy when he heard of the return of "*Général Vendémiaire*," who was once more to save the Republic. Of the five directors, Sieyès, though a regicide, had given up hope of saving the country except by a dictatorship, of which he hoped to be the head, with Bonaparte as his strong right hand. Roger-Ducos was of the same opinion. The third, Barras, was corrupt, and would do anything for money. Only the remaining two, Moulin and Coghier, were immovable in their Jacobinism, and had to be silenced. Resistance could come only from political circles, the assemblies, or perhaps from part of the army, where Jacobinism was still strong. The conspirators were assured in advance of the support of public opinion. It is, therefore, essential to note that the *coup d'état* was conceived and organized by Sieyès, who took charge of the

parliamentary side, while Bonaparte was an executive agent charged with assuring the support of the army. We must not forget that from its origin to the days of *Fructidor* and *Prairial*, the Revolution had undergone many forcible changes and had violated its different constitutions over and over again.

The pretext for the transference of the two legislative assemblies from Paris to Saint Cloud on the 18 Brumaire was a terrorist plot invented for the occasion. The plan, though well laid, all but miscarried. On the first day, that of 18 Brumaire, all went well, and, as the Convention had done in *Vendémiaire*, the assemblies placed Bonaparte in command of their forces. On the morrow at Saint Cloud, affairs took a dangerous turn. The Upper Chamber or Council of the "Ancients" had been won over, but the lower or Council of the Five Hundred, whose Jacobin members had had time to summon their forces, greeted the general with shouts of "Down with the dictator! Outlaw him!" Bonaparte lost the thread of his speech, lost countenance, and for a moment was surrounded by a threatening crowd of deputies. Soldiers came to his assistance; however, the day would have been lost but for his brother Lucien, who had made his way in politics and was president of the assembly. Declaring that the right of free speech had been outraged, he dramatically threw off his insignia and rushed into the court of the Orangery to harangue the still hesitating soldiers. Bonaparte, having recovered from a fainting condition, appeared, his face bleeding where, in his agitation, he had scratched it. This made the soldiers think that he had been wounded. General Leclerc, his brother-in-law, thus charged at the head of his grenadiers and cleared the hall of the refractory deputies. That very evening Bonaparte, Sieyès and Roger-Ducos were elected "consuls" by the Council of the Ancients.

The Revolution was not over. Bonaparte was to continue it under monarchical forms, and to give it at last a government. Sieyès dreamed of giving a constitution to France, but France had worn out so many constitutions during the last ten years! Bonaparte, who had used the "ideologues" as stepping stones to power, now made it clear to them that they had a master; and of Sieyès' constitution, only such portions as suited him remained. Authority was narrowing its limits. Five directors had given place to three consuls.

First Consul.—Immediately after, Napoleon became the first, the only one, elected for ten years. Public opinion gave him what was practically unlimited power. Disillusion and anxiety made him master of France. Some were tired of violence and disorder. Others, who had profited by the Revolution to possess themselves of national property, feared the return of the Bourbons and its restoration to its former owners. The mass of the people therefore, desired the consolidation of the new régime. Had it not been for the 18 Brumaire, it is probable that the restoration of the legitimate branch would have taken place much sooner, before the Napoleonic empire had consolidated the results of the revolution by permanent institutions. The great mistake of the royalists was to look upon Bonaparte as another General Monk. He replied with disdain to the overtures of the comte de Provence—the future Louis XVIII. The royalists in their turn hastened to resume the struggle against him, thus definitely marking him as the representative of the "revolution in arms."

The Revolution was further indissolubly bound to its idea of "natural frontiers," and could not surrender the conquests which the rest of Europe refused to recognise. The war had to go on, whether they liked it or not—a fact which entailed government by a soldier. With the rest of his heritage, Bonaparte had to accept the necessity which had made the weak directory as warlike as the Convention. His term of power served merely to postpone the inevitable catastrophe.

Reforms.—His first work was to restore order and to regulate the administration of government. Here his lack of prejudice helped the first consul. As has already been said, being of French education, but not of French origin, he neither disliked nor regretted the old régime. He was thus able to adopt the strong points of the old monarchical system and reject the weaknesses of revolutionary democracy. The Revolution had made the system of election universal, in the civil service, in the magistracy, and

in the police: a fault which killed successive governments. Bonaparte replaced the elected committees by prefects and sub-prefects, thus re-establishing and multiplying the old *intendants*. Unwilling to restore completely the independence of the magistracy, of which the parlements had availed themselves against the crown, he gave the government the right to nominate magistrates, while making them, in the interests of justice, irremovable. Thus, making use of the experience both of the monarchy and of the revolution, Bonaparte framed the system known as the constitution of the year VIII. based on administrative centralization which subordinated the nation to the State, and which has been so convenient for governments that it has been kept in being by all the succeeding régimes. Altered only in detail, it subsists today.

At the outset Bonaparte justified the hopes aroused by his *coup d'état*. The mass of the people longed for peace at home and abroad. He appeared to fill the rôle of peacemaker. Having rid himself of Sieyès, he associated with himself, for form's sake, two other consuls, Cambacérès and Lebrun, men of ripe age and moderate views, the latter of whom had been secretary to Chancellor Maupeou under Louis XV. When a plebiscite was taken, the First Consul was approved by three million votes. He immediately reassured both the solid middle class, and the revolutionaries who had enriched themselves during the Revolution. He wiped out the last relics of Jacobinism, by suppressing the progressive forced loans, and the law of hostages. He re-opened the churches and pacified the Vendée by putting an end to religious persecution and thus indicating a forthcoming *concordat* with the Pope. With the help of a former official of the monarchy, Gaudin, who became duke of Gaeta, he reorganised the finances, and prepared the way for a return to a stable currency.

Marengo and Hohenlinden.—Abroad his task was more difficult. There is no reason to think that Bonaparte was not sincere in trying to put an end to hostilities, though he may have wished to prove to the peace party that peace was unobtainable. The proof, in any case, was quickly forthcoming. The emperor of Russia having retired from the coalition, it remained to deal with England and Austria. The first consul offered a cessation of hostilities. It was a mistake to think that England, so long as she remained mistress of the seas, would ever allow France to retain possession of the mouths of the Scheldt. Pitt refused. Then Bonaparte made another miscalculation. A smashing victory on the Continent would, he thought, compel England to yield. He persisted in this erroneous idea until Waterloo. His history henceforth is a striving for the impossible, *i.e.*, the capitulation of Great Britain on a point she had never admitted—the annexation of Belgium—by a France, which was powerless at sea.

Seven months after the 18 *Brumaire*, he boldly crossed the Alps by the Great Saint Bernard to compel Austria to make peace. On June 14, 1800, the hardly won victory of Marengo made him once more master of Italy. Together with Moreau's victory at Hohenlinden in December, it forced the Emperor Francis to sign the treaty of Lunéville, by which Austria recognized all the conquests of the Revolution. The left bank of the Rhine became part of France, and was divided into departments. This was the triumph of Bonaparte and of the revolution. For the first time in history France had regained her "natural frontiers," those of Gaul as known to Caesar.

By the treaty of Lunéville, the British government lost her last Continental ally. The war was costing dear, and many people were weary of it. Trade was severely affected. The first consul, who knew this, resumed in appearance the preparations for invasion, which had been begun in 1797. When, after the fall of Pitt, negotiations were begun with the London cabinet, he strove to drive a bargain, renouncing all claims on Egypt. In March 1802, the treaty of Amiens was signed. It was, and could only be a truce, but the French saw in it definitive peace, and the prestige of the first consul was increased.

Extensions of Power.—In the midst of his success there was one seed of anxiety. He was in power only for ten years. Three had already passed, and opposition was beginning to make itself felt. A Jacobin conspiracy was discovered. Soon after he narrowly escaped being killed by an infernal machine. Former ter-

rorists were thought to be responsible, but Fouché, the minister of police, found that the criminals were royalists instigated by the irreconcilable Cadoudal. Then the Tribunal instituted by Sieyès, opposed Bonaparte's favourite ideas; the Concordat with the Pope, the Order of the Legion of Honour, the Civil Code. Their opposition would become more formidable as the ten year period drew to a close. Definitely to establish the Consulate, and to make it safe from attack, permanence was desired. Thus by a natural progression opinion tended towards the revival of the monarchy in favour of the first consul. He himself was silent, asked for nothing, and let his friends work for him. This they did most effectively.

After the triumph of the peace of Amiens, they proposed a national token of gratitude. The Senate accorded only a prolongation of power for a further ten years. This was a discomfiture. Then Cambacérès thought of consulting the people whether Napoleon Bonaparte (his Christian name was beginning to be used officially) should be made consul for life. It was carried by three and a half million to less than ten thousand votes. The first consul also received the right to choose his successor (Aug. 1802). Although he then had no children, there was nothing to prevent him from choosing his son, if he should have one.

Hereditary monarchy was thus on the point of being re-established, after so many solemn protestations to the contrary. From that time the sovereigns of Europe began to regard Bonaparte as one of themselves. They watched him "climbing step by step towards the throne," though there were to be further happenings before he reached it. It would be an error to accuse him of having sought to gain the crown by means of a new war. The establishment of the empire was an indirect consequence of the renewal of hostilities in May 1803, the immediate cause of which was a dispute over Malta and the interpretation of the treaty of Amiens, though for reasons easily understood, and beyond the control of statesmen, peace could never have been more than a truce. Could England allow France to remain in permanent possession of the finest coast line and most valuable ports of the Continent from Rotterdam to Genoa? To put the question is to answer it. And we must remember that Napoleon had received Belgium and Holland in trust for the Revolution.

Counterplots.—France and England slowly prepared for a struggle which this time must be carried to the bitter end. The twice abandoned plan of invading Great Britain was again resumed, and a camp was formed at Boulogne. Meanwhile the irreconcilable royalists, encouraged by the first consul's new difficulties, conspired with General Pichegru to assassinate him. Georges Cadoudal, who had landed in France, succeeded in implicating the celebrated Moreau, jealous of the first consul. The discovery of this plot infuriated Bonaparte. He accused the *émigrés* of ingratitude, publicly affirmed his republican sympathies, and declared that the intention was to destroy the revolution in his person. He determined to strike.

A young prince of the house of Condé, the duke of Enghien, one of the Bourbons, was forcibly seized on the territory of the duchy of Baden, summarily tried and shot. Bonaparte has been universally condemned for this judicial murder, which set "a ditch filled with royal blood" between the older dynasty and the throne upon whose steps he stood. His regicide monarchy was no longer suspect even to the fiercest republicans. Just as the infernal machine had contributed to the success of the first plebiscite, the conspiracy of Cadoudal and Pichegru facilitated the proclamation of the empire. The first consul had escaped the conspirators, and the danger helped his cause.

THE FIRST EMPIRE

The consulate for life seemed too precarious; a Napoleonic dynasty would survive its founder. Since his enemies, who were the enemies of the revolution, wished to destroy him "he must be made king or emperor, so that heredity should reinforce his power by ensuring him of natural and unquestioned successors and, by rendering useless crimes against his person, should remove the temptation to commit them." (Thiers.)

Thus France returned to hereditary monarchy, approved by a

unanimous vote of the Senate, and by a plebiscite. The empire was proclaimed on May 18th, 1804, the title of emperor being chosen because the word king was inseparably connected with the Bourbons, and because it sounded more impressive, more military. It evoked, moreover, memories of Rome and of Charlemagne. And, like Charlemagne, Napoleon wished to be crowned by the Pope, not in Rome but in Paris. After some hesitation Pius VII. granted his request. On Dec. 2, at Notre Dame the amazing ceremony took place, and the soldier of the revolution became the anointed of the Lord. Moreover he took the crown from the hands of the Pope, and placed it on his own head. And Josephine the Creole adventuress, became empress. But Napoleon could dare all. He built up a new nobility, he gathered together a court. France approved of everything. When the wife of Marshal Lefebvre (the celebrated *Madame Sans Gêne*, who had been a washer-woman) became the duchess of Dantzic he dared even ridicule.

Boulogne, Ulm and Cadiz.—The empire united the old France with the new; in it revolutionary and monarchical ideas were combined. There was general satisfaction. Prosperity had returned with ordered government. No one troubled about the one weak point. The empire could not be really established, nor the conquests of the revolution assured, without the defeat of the British power. Napoleon did not forget it, and in the midst of his re-organization of home affairs, his thoughts were on the camp at Boulogne. He knew that to settle finally with England he must overcome her on her own ground, and must have therefore, were it only for one day, free passage across the Channel. A third coalition was forming. He could, he was sure, defeat its forces by land, but this new victory would be no more effective than earlier ones, so long as the British navy was undefeated. With the help of Admiral Decrès, Napoleon had laboured since the days of the consulate to re-establish the French navy, ruined by the Revolution. But a navy is not built in a day. Failure at Boulogne was to change the fortunes of the empire.

Yet the plan was bold and simple. France had two squadrons. The destruction of one mattered little if, while it fought, the other could slip into the Channel and for 24 hours assure the transport of the troops gathered at Boulogne. On this strategy everything turned; it failed. Villeneuve failed Napoleon, as Grouchy was to fail him at Waterloo. The admiral was uneasy about his equipment, his officers, and his raw and untrained crews. His anxiety was shared by Decrès, the minister of marine. Napoleon spent the month of Aug. 1805 in cruel suspense. Villeneuve, he learnt at last, had not dared to enter the Channel and instead of bearing towards Brest, was making sail to the south. Once more the invasion of England must be abandoned, or at least postponed. Austria was openly threatening, Russia was arming, Prussia could not be depended upon. Austria must be brought to the knees without delay. Napoleon broke up the camp at Boulogne, marched into Germany with amazing rapidity ("The emperor makes war with our legs," said his soldiers) and forced General Mack to surrender at Ulm on Oct. 19.

Two days later this magnificent victory, with all those which were to follow it, was nullified. Villeneuve, blockaded by Nelson in Cadiz, had tried to escape. The British fleet, though smaller in numbers, had destroyed the Franco-Spanish off Cape Trafalgar. From that day the French empire was doomed. Napoleon was faced with the hopeless task of subduing England, absolute mistress of the seas. All his future was governed by that impossibility.

Austerlitz and Jena.—Because he had not crossed the Straits of Dover, he was to go in vain even to Moscow. In vain he sought to triumph first over the Continental powers, hoping then to find the British government discouraged and in a mood for compromise. The Russians having offered battle, he defeated them, and also a fresh Austrian army, in the most brilliant of his victories, that of Austerlitz (Dec. 2, 1805), exactly a year after his coronation. In a few weeks the third coalition was wiped out.

The armies of France, under the single command of a man who was a military genius and an absolute sovereign, seemed invincible. Napoleon, and perhaps he alone, knew that no decision had been

reached. He rejected Talleyrand's plan for a reconciliation with Austria, and, returning to the idea which had inspired his Egyptian expedition, planned to strike at England through the East. By the peace of Pressburg he made of a subjugated and diminished Austria a means of communication with Constantinople. The vision was taking shape. To realize it, however, he must dominate all Europe. Within a few years he exhausted the Empire in the attempt. With the conquest of Belgium as a starting point, the revolution urged its successor to vast enterprises, for which neither the military genius of Napoleon nor his political ability would suffice. It was not mania for conquest but the logical development of these schemes which led him to annexations and dangerous territorial adjustments which disquieted all Europe. His brother Joseph became king of Naples, his brother Louis king of Holland. He formed the states of Southern Germany into the Confederation of the Rhine, with himself as president. Prussia, charged with closing the Baltic to the English, was promised Hanover, and the Bourbons, dethroned in Naples, were to have the Balearic isles. After the death of Pitt, he tried to conciliate England by offering secretly to restore Hanover. These diplomatic moves served only to make him two enemies, Prussia, which he had humoured for so long, and Spain, a former ally.

The Prussian campaign saw another of the lightning strokes which he understood so well. The Prussian Army, which had lived on the reputation gained under the great Frederick, was routed at Jena (Oct. 1806). In a few weeks the defence had collapsed, and Napoleon was master of the greater part of Prussia.

The Subjugation of Europe.—Since Prussia had refused to lend herself to his schemes, he would make northern Germany another annex to his empire, himself closing the Baltic and eventually all Europe, to English commerce. From Berlin he promulgated the Continental blockade, an idea arising naturally out of the situation, simple, easy to set out on paper, but entailing the suppression of the independence of all the nations of Europe, since the prohibition of trade with England to be effective must be general. The Continental blockade was the consequence of and the counter-stroke to Trafalgar.

But Napoleon was caught in a net from which there was no escape. He had set himself an endless task. After Ulm had to come Austerlitz, after Austerlitz, Jena. After Jena he had to complete the conquest of Prussia, and to complete it, to defeat Russia, penetrate further into the East, cross the Vistula. At Eylau (Feb. 8, 1807), three hundred leagues away from France, he fought in the snow a bloody and inconclusive battle. A new effort, the calling up of next year's conscripts was demanded of Frenchmen "that peace might be won." In June at Friedland, the *grande armée* was again victorious.

Once more Napoleon had the illusion that the goal was reached, that he was master of Europe and could hold England to ransom. The czar Alexander, highly strung and impressionable, was now won over to the idea of an agreement with the emperor of the French for a policy of partition on 18th century lines. This time Turkey was to be divided instead of Poland. Napoleon was convinced that, allied with Russia against England, able to close the Mediterranean against her, threatening her even in India, he would force her to her knees. The meeting at Tilsit, and the conclusion of the pact of friendship between the emperor of the East and the emperor of the West, seemed to justify the costly victories which had led the French army as far as the Niemen.

Spain, Prussia and Austria.—The first disappointment was that the Franco-Russian alliance determined England to fight more fiercely than ever; her answer was a declaration of war against Russia, and the bombardment of Copenhagen. The Continental blockade everywhere led to increasing difficulties. Portugal showed no eagerness to shut out English trade. Junot had to be sent there with an army. Spain was also giving trouble, and Napoleon determined to drive the Bourbons from Madrid. As if he were transferring prefects, he placed his brother Joseph on the throne of Charles IV., and succeeded him at Naples by Murat, who had married Caroline Bonaparte. At the same time the occupation of the Papal States by General Miollis, charged with enforcing the blockade, embroiled him with the Pope. The

system drove Napoleon to increasing severity. To hold Germany and Italy, together with the Adriatic coasts, and the Spanish peninsula, would soon require a standing army of a million men, while the patience with which his conquests and his violence were endured would decrease in proportion to the dispersion of his troops.

Spain gave the signal for resistance. The Spanish people refused to recognise Joseph, and a wide spread insurrection broke out. When, in July 1808 General Dupont surrendered at Baylen, the Napoleonic empire suffered its first military reverse. The news resounded all over Europe. At the same time an English army landed in Portugal and Junot succumbed to superior numbers. Napoleon's desire to direct and control Spanish affairs had not only caused the English to be received as liberators, but had committed himself to an endless struggle against a people in arms. The uprising of the Spanish nation was infectious. In Prussia, in Tirol, in Dalmatia, patriotism was extolled, and the idea of a holy war for national independence took root and grew. In later days the emperor realized that Spain had been his first check, and that the limit of his power had been attained. In spite of a fresh interview at Erfurt, at which the two emperors paraded their friendship before an audience of kings, the Franco-Russian alliance languished. The partition of Turkey was hindered by the question of Constantinople, which neither emperor wished to see in the power of the other. Alexander was beginning to doubt the power of his new friend. Napoleon, feeling that the ill-success of his policy in Spain was injuring his prestige, determined himself to cross the Pyrenees, and re-establish Joseph in Madrid.

Incited by England and lavishly supplied with English money, Austria took advantage of his absence to re-enter the struggle. Napoleon had to return in haste from the Ebro to the Danube. The Austrian plans were carefully laid, and their opposition was far from negligible. Essling was a difficult, and Wagram (July 1809) a costly victory, but in both he carried the day.

Russia.—From these very successes, however, there arose a further complication. Napoleon had made use of Poniatowski and his Poles against the Austrians. Alexander, who, in any case, had remained neutral, feared that Napoleon was planning the reconstitution of Poland. Abandoning his former ally, he denounced the Continental blockade, and had in his turn to be encountered. The idea of conquering England by Europe and Asia, the sea by the land, had brought about a result which, though it seems at first absurd, was yet the logical conclusion.

It was with no light heart that Napoleon decided to carry the war into Russia. He still hoped that it might not be necessary, if Spain were subdued and if the United States, to whom he had ceded Louisiana and promised Florida, declared war on England, which, attacked in its vital interests by the Continental blockade, would at last sue for peace. There was no doubt that the blockade was having a disastrous effect on British trade; its results on the commerce of other nations were no less serious. Holland refused to enforce it, and Napoleon was obliged to resume control from his brother Louis, who had espoused the cause of his new subjects. He annexed the country, and divided it into departments, thus giving England a fresh reason for remaining under arms. In this way the Continental blockade led either to fresh wars or to expansions of territory which the English inevitably refused to recognise, since they had never recognised those revolutionary conquests which the new ones consolidated.

France was growing uneasy. Common sense made it clear that this extension of territory and of war could not go on indefinitely, and yet no end was in sight. Far-seeing members of the emperor's own circle, such as Talleyrand and Fouché, began to fear that affairs were going wrong. "If it only lasts," said Laetitia Ramolino, *Madame Mère*. Yet the empire never seemed so great, nor the future so secure as in 1810.

Marie-Louise.—Already on a level with kings, Napoleon in his second marriage equalled the proudest dynasties. The head of the house of Habsburg gave him the hand of his daughter. Josephine, though she was loved by the people and her dethronement regretted, was growing old and she had given him no heir. He was tired of her, and anxious to ensure the succession. The

emperor of Austria must have shared his confidence in the future, since he was willing to accept the "Corsican ogre" as his son-in-law. The marriage contract with the archduchess was modelled on that of Louis XVI. and Marie-Antoinette, into whose family he was now admitted, in one of the most extraordinary episodes of even his life. The following year Marie-Louise bore him a son; the empire had an heir, who was given the title king of Rome, as the heir to the Holy Roman Empire had been named king of the Romans. But in 1811 Rome was but the capital of the department of the Tiber. The pope had been deported to Savona and was about to be imprisoned at Fontainebleau. By the Continental blockade the restorer of Catholicism in France had been led to alienate Catholics all over the world. Nevertheless, excommunicated, having driven the Bourbons from Naples and from Madrid, the man who 20 years before had been an insignificant officer with neither name nor fortune, married a daughter of the Habsburgs. Confident in his star, he carried all before him.

Though his marriage gratified his ambition, Napoleon had decided upon it only after the failure of negotiations for an alliance with a sister of Alexander. He would have preferred a Russian princess, for more than one old veteran of the Revolution, remembering Marie-Antoinette, asked why the "little corporal" should marry another "Austrian." But the Russian emperor was gradually disengaging himself from the alliance, on which Napoleon was ceasing to rely.

Moscow.—Realising that the Russians would never consent to the extension of the French empire, which under the necessity of the Continental blockade had ended by annexing the Hansa towns of Bremen and Hamburg, and making them the principal cities of two of its hundred and thirty departments, he saw that war was inevitable. French territory now stretched to the Baltic, and the nearer its boundaries approached those of Russia, the greater was the danger of conflict. Difficulties arose continually over Oldenburg, Poland, the East, and the reluctance of Russia to abandon trade with England. The two allied emperors were arming against each other. These preparations were themselves a further offence. Convinced that this new struggle had been decreed by fate, and that his work would not be accomplished till he had vanquished Russia as he had vanquished Prussia and Austria, Napoleon now assembled for the campaign of 1812 the greatest army which the world had yet seen, an army of "twenty nations" made up of contingents from all the peoples allied to or dependent on France, a sort of Western crusade against Asiatic Russia. By natural inclination, as much as by policy, Napoleon raised again for this crusade the battle cry of the Revolution, the liberation of nationalities, of which the reconstitution of Poland was to be the token. He forgot that the Spaniards were already fighting for their independence, and that the nationalism, awakened by principles of the Revolution, was stirring the people of Germany. Alexander, who could play many parts, also spoke the language of liberalism, invoked justice, enlisted on his side the countries defeated and subjugated by France or in rebellion against her, and prepared for peace with Prussia and Austria by complicity in the partition of the Polish provinces. Napoleon was thus to stake everything on the inevitable Russian campaign. Victorious, he would be master of the East, of Constantinople, of all Europe, and would at last force the English to capitulate. Defeated, he himself would have given the signal for the debacle. The war which began in 1792, having carried the French to the gates of Moscow was to return by a swift and violent revulsion to the gates of Paris.

In June 1812 the *grande armée* crossed the Niemen. According to their custom, the Russians declined battle. Alexander had said that he would retire if necessary beyond Tobolsk, while Napoleon imagined himself dictating peace from Moscow. The Russians set fire to the city, and made no peace. Then began a retreat which after the passage of the Beresina became a disaster. In the month of December, Ney and Gérard arrived at Königsberg almost alone. The *grande armée* had melted away. Realising the extent of the catastrophe, and its probable effects in Europe and in France itself, the emperor had secretly left the army, which was kept in ignorance of his departure. The news of General Malet's

conspiracy, which had reached him in Russia, had shown him how precarious was his position and how much weakened his prestige.

The Loss of Germany.—The subsequent history of the Empire is the story of a rapid return to the conditions under which Napoleon had assumed the dictatorship in 1799. The Republicans themselves on the 18th *Brumaire* had entrusted him with the task of saving the Revolution and its conquests. To this end France had allowed him to take the crown, to found a dynasty, to overrun three-quarters of Europe and to raise countless armies. All in vain. In a few months he was back at his starting point.

The Spanish insurrection of 1809 had encouraged England to persevere, and had revived the resistance of the conquered peoples. The disasters of the Grand Army in 1813 spurred on his enemies still more. "A few more sacrifices," said the English, "and our end is accomplished." Not even the long hoped for declaration of war by the United States, due not to French diplomacy but to the doctrine of the freedom of the seas as opposed to the English "tyranny at sea," could affect the determination of the British government. Everything pointed to a vast change of fortune in favour of the cause of which England, at one moment, had remained the sole champion. Nationalist propaganda was bearing fruit in Germany. Prussia, while still protesting fidelity to Napoleon, had shifted her allegiance, and secretly reconstituted her army. A Prussian corps in French service, commanded by General York, went over to the Russians. Its defection made a great sensation in Germany and hastened the continued retreat to the Elbe of the remnants of the French army. The Prussian government then unmasked and, obedient to popular opinion, proclaimed a war of liberation and independence.

Napoleon chose to consider his Russian defeat as an accident. In Germany it would always be easy for him, he thought, to beat the Prussians and the Russians; having raised and trained a fresh army he did, in fact, beat them at Lutzen and at Bautzen. The campaign of 1813 opened well. He was, however, justly apprehensive of Austria, and instead of following up these fresh successes he agreed to an armistice, so as to be ready for the third adversary. A coalition of Austria, Prussia and Russia had no terrors for him. He wished to settle with it as quickly as possible, thinking that he held enough cards to secure even from England a favourable peace. The victory of Dresden (Aug. 27) seemed to justify this. But, one after the other, his generals, badly served by their contingents from the Germanic Confederation, were beaten in the field, and his plans were delayed. At Leipzig, where he had returned to prevent the junction of his three opponents, Napoleon fought a three days' battle (Oct. 16-19), during which his Saxon troops went over to the enemy. Having lost this immense battle, and all Germany with it, he had to fall back to the Rhine. In November what had been the *grande armée* entered Mainz, after fighting its way through the Bavarians who in their turn had betrayed him.

Was it possible, on the banks of the Rhine, to secure peace on the basis of "natural frontiers"? The question had been identical under the Revolution. Prussia showed herself at last as the German power most fiercely opposed to France, and England insisted on the renunciation of Antwerp. This was, as it had been during twenty years of war, the question at stake.

Disintegration.—Holland had risen against French rule. Belgium was tired of conscription and of taxes, and there also was awaking an old, invincible consciousness of nationality. The British government, well informed on the condition of France, was aware of her exhaustion. Everything, they knew, had been organized for conquest, nothing for defence. The Allies were much superior in numbers. Even within its own boundaries the Napoleonic empire was tottering. Their determination to finish the business once and for all carried even more weight than Prussia's hatred, and the negotiations which took place before the Allied entry into Paris were for that reason insincere. It had been clear since 1798 that, with England undefeated, France could make peace only on returning to her former frontiers.

No one knew better than Napoleon himself that he was, as the

Convention and the directory had been, bound hand and foot by the war and its conquests. He must defend those conquests to the end, or perish with them, as the Revolution had perished. The very nature of his power and the conditions on which he had received it, forbade him that honourable and prudent peace which he has been vainly reproached for failing to achieve. First the allies would have none of it, though their unwillingness was veiled to give the impression in France that only the insensate ambition of the emperor stood in the way; secondly, no government of revolutionary origin could accept the former boundaries. The situation was the same as in 1799. "As things are," said Napoleon, "no one but a Bourbon can succeed me."

The Bourbons, however, succeeded him for another reason. When the Allies invaded France in 1814, they were not in agreement on the form of government. They had not made war for the re-establishment of the monarchy before or now. The Austrian emperor preferred the regency of his daughter Marie-Louise, which would have given him control of French policy. The emperor of Russia dreamed of a king of his making, such as Bernadotte, one of the luckiest adventurers of the Revolution, who by an unprecedented combination of circumstances had become crown prince of Sweden and had betrayed Napoleon. Prussia, concerned only with her own aggrandisement, cared little who ruled in France provided that she obtained her share of the spoils.

Thus Castlereagh, who wished to see France smaller, but free and in subjection neither to Austria nor to Russia, became convinced that a Bourbon monarchy alone would fulfil England's conditions, since, according to Albert Sorel, "this government of principles and not of expedients would be neither the debtor nor the client of any of the Allies." Unknown to, or uncomprehended by the French, this was the reason for the restoration, which to them seemed to be arbitrarily imposed by the enemy, though, in accordance with the English theory of the balance of power, it was intended to preserve their national independence.

Napoleon's campaign in France, the most brilliant of them all, was a barren masterpiece. Albert Sorel has compared his victories, Brienne, Champaubert, Montmirail, Montereau, to that of Valmy. The Allies hesitated and wondered whether to negotiate. But just as the Revolution had demanded that the enemy should quit French territory, so Napoleon insisted on the guarantee of "natural frontiers." He could do no less, but the object of the coalition was to deprive France of them. "We must reassume the uniform and the courage of '93," he said in Feb. 1814. He clung instinctively to the Revolution, and welcomed the proffered assistance of Carnot, former comrade of Robespierre, and one of the few revolutionaries who had held aloof from the empire. The allies on their side remembered that when, after Valmy, the invaders had retired behind the Rhine, Revolutionary France had decided to pursue them. This recollection stiffened their determination, and strengthened their alliance. The four powers bound themselves afresh by the pact of Chaumont, and resumed the offensive, determined to dictate terms of peace.

Everything was crumbling around Napoleon. With the last levies which France could give him, scarcely more than children, he again tried to hold back the enemy, then to outflank and defeat them. His plans failed for want of men. On March 30 the Allies were masters of Paris, and a German wrote from Montmartre, "Nine and a half centuries ago our emperor Otto planted his eagles on these hills."

Abdication.—On April 11, 1814, at Fontainebleau, Napoleon abdicated. Not only had his Senate, the child of the *Corps Législatif* of *Brumaire*, itself the child of the Convention, deserted him and declared for the Bourbons, but his marshals fiercely urged him to renounce his sovereignty and leave the country. They had returned to the position before the 18 *Brumaire*, from which the Directory had sought to escape. It is again Albert Sorel who notes that the empire ended, as the consulate began, by one of those "days" which had overthrown so many revolutionary governments. On May 5, Louis XVIII. entered Paris, while the fallen emperor landed on the island of Elba where his sovereignty was recognized. The former master of Europe now reigned over a few square miles. But he was only forty-five and in the full force

of his powers. A man of such immense energy and such ardent imagination could not resign himself so easily to defeat.

Only 25 years separated the beginning of the revolutionary era from his fall. A quarter of a century, however crowded with events, is a short space of time. What had happened? In the part of its programme which included republican government, and "natural frontiers," the Revolution had doubly failed: first, when to save itself it had had recourse after the 18th *Brumaire* to a dictatorship, to absolute sovereignty, to the empire; and again when after incessant fighting for "natural frontiers," the empire had ended by laying France itself open to invasion. Conditions which the Revolution would never accept even though the refusal involved a military despotism, were now imposed. France was obliged to return to her former boundaries, and this involved the restoration of the Bourbons. It was the only possible solution, and there were few in 1814 who did not accept it. Talleyrand, who was far from being a legitimist, played a principal part in the restoration, simply because he realized that it was the only solution. Any government, whether republican or imperial, which sprang from the revolution, was doomed to war, and France had already waged war to the limit of her strength. The monarchy alone could assume the heavy responsibility of concluding peace on the terms offered. Hence when the French had forgotten the disasters and the despotism of the empire arose the reproach that the Bourbons had "returned in the baggage waggons of the enemy."

The return of Louis XVIII. was accompanied by the grant of the "Charter," and representative government. He did not restore the institutions of pre-revolutionary France, but on the contrary, retained those of Napoleon, of the year VIII., even confirming the greater number of his prefects in their office. It remained to make peace in Europe. Louis XVIII. and Talleyrand, making use of the jealousies which had arisen among the allies, sought to make the general settlement as favourable as possible to France. The Congress of Vienna was still sitting when, early in March 1815, the news came "like a bombshell" that "Bonaparte" had escaped from Elba. It had all to be done over again.

There are few examples in history of such sentimental and passionate episodes as the return from Elba. Though the good sense of the French protested against the adventure, it caught at their hearts. Napoleon brought with him so many memories, and with them the tricolor. The daring of his landing in France recalled the return from Egypt. He had only to appear, and almost all France rushed to support him. Yet moderate men realized that the emperor's new adventure was all but hopeless, and would end in a catastrophe even worse than that of 1814. Liberals regretted the loss of the "Charter." France was sick of war, and the abolition of conscription had been the most insistent demand made on the Bourbons. Napoleon maintained that he had been recalled by the people, universally dissatisfied with the restored monarchy. There was, of course, unavoidable friction between the old émigré society and the new. There were in particular soldiers who had held out alone in Germany, Holland and Italy, and had not returned to France till after the convention of April 23. These had not witnessed the invasion, and felt that the fall of the emperor had been undeserved. There was also to be reckoned with, the discontent of the officers who had been placed on half pay.

None of this was really serious, however. Only the presence of Napoleon himself, escaped from his island prison, could have brought about the flood of popular feeling by which he re-conquered France in three weeks. He had only to appear and all was forgotten, the disasters of yesterday and those which his return implied, the slaughter which had brought curses on his name, the detested conscription. Officers and men rallied round him. He had not lost his power of appealing to them, and he stirred their hearts by memories of past glory. After the first moments of hesitation the detachments first sent against him declared for him. Grenoble, then Lyons opened its gates. Marshal Ney, who had undertaken to apprehend him and to bring him back if necessary in a cage, wavered, was carried away, and fell into his arms.

The Hundred Days.—Having landed in the gulf of Juan with a handful of men on March 1, 1815, he was at the Tuileries on the 20th, and Louis XVIII. had fled to Ghent.

A hundred days: the adventure lasted no longer, and was doomed from the outset. Three months' madness. To understand why Napoleon, who, ten months before, had been deserted and denied by all, became the master of France in three weeks in a rush of passionate enthusiasm, we must take into account the change in himself, and the new rôle which he played in opposition to the Bourbons. He was not only a military genius. He was a supremely able politician, and his talents had been perfected during the revolution. He now awoke its memory, talking to the soldiers of glory and to the people of peace and liberty. The former despotic emperor returned a demagogue. Two things menaced him. There was first the fear that the allies would again take up arms, but that he assured the people would be prevented by his father-in-law, the emperor of Austria. Then there was his own despotism. But he told the peasants that they were threatened with the revival of tithes, seigniorial privileges and rights. "I come," he said, "to free you from bondage and serfdom." He who had restored the rights of the Church, and founded a new nobility now incited the mob against the nobles and the priests. To the Liberals he promised representative government, the freedom of the press, everything which Louis XVIII. had already granted, but with a new revolutionary tinge. The idea of a liberal Napoleon conformable with the principles of the Revolution, remained in men's minds. From it dates that alliance of the Bonapartists with the Liberals which disturbed the restoration and the reign of Louis Philippe, and paved the way to the era of Napoleon III.

Abroad the consequences of the return from Elba were no less grave. The allies at Vienna learned the news on March 13. They immediately declared the emperor an outlaw. The pact of Chaumont was renewed. Resumption of the war was certain, and new disasters probable for France. Talleyrand, the French representative at the Congress, was in a cruel position. Foreseeing the event, he associated himself with the allies in order at least to keep the conditions of the Treaty of Paris, and to prevent the next treaty from being made even more severe. It was easy afterwards to pillory this prudent decision, and to assert that the Bourbons had joined with the enemies of the French people. When those who had compromised themselves in the Hundred Days sought for an excuse, they used this treacherous argument.

DOWNFALL AND CAPTIVITY

Waterloo.—Napoleon had never held the illusion that the allies would permit him to reign, nor that he could reign, over a France reduced to its former boundaries. He was still subject to the law which had in the past driven him incessantly to battle. Outlawed by Europe, he prepared to fight. He could still command his followers, but the enthusiasm of the early days had evaporated and there were sinister forebodings. There were many abstentions from the plebiscite held, as before, to approve the supplementary Act to the constitution. The assembly of the *Champ de Mai* resuscitated as the festival of Federation, was gloomy. The spirit of the people was exhausted, their minds disturbed, and Napoleon's supporters uneasy. To prevent a new invasion, the Emperor left for Belgium on June 12 with the intention of separating Wellington and Blücher, who had a hundred thousand men more than he, and defeating them successively. In spite of a success at Ligny, he failed to prevent the junction of the English and the Prussians. This was partly due to what is usually called ill-fortune, but is really the resultant of many forces. Grouchy, a second-rate general to whom Napoleon had given a command in reward for political services, blundered, and remained inactive during the great battle which took place on June 18 at Waterloo—the name of a disaster unparalleled since Trafalgar. On his return to Paris on June 20 no other course but a second abdication was open to Napoleon. All was over. The Napoleonic drama culminated in disaster.

It would appear that in order to strike the imagination of mankind a hero's life should end with a great misfortune. If he had died a natural death in his palace, or fallen on the field of battle, Napoleon would never have become to posterity the figure we know. Lives like his must end in martyrdom, which crowns them with the pity caused by human suffering and the respect due

to misfortune. Saint Helena idealised the emperor's memory, and his gaolers unwittingly prepared for him a sort of poetic immortality. Though his imprisonment in a distant island was a punishment relatively slight as compared with the torture of Joan of Arc, and though the man who placed the imperial crown upon his own head had little in common with the young girl who led her king to his crowning at Reims, there is some similarity in the moral effect and the historical renown of their death. The last phase of Napoleon's life may be regarded as his transfiguration.

After Waterloo, the energy which his presence had re-awakened relaxed. On his return to Paris he felt himself abandoned. The Chamber declared itself against him, and appointed an executive commission to govern with the ministers. He must either forcibly dissolve it, or abdicate. He decided to abdicate in favour of his son, the king of Rome, and made known his intention of going to the United States. The executive commission replied that two frigates, then in waiting at Rochefort, were at his disposal, and requested him to hasten his departure. He remained a week longer at Malmaison, then, as a last despairing throw of the dice, offered his sword against the invaders as a simple general. He then undertook to leave for America. His offer was refused. He left Malmaison on June 29 and arrived at Rochefort on July 3.

The two frigates were there, but the "Bellerophon" and other English ships were cruising before the harbour and blocked the outlet. One hope was left, to slip past and get out to sea. Napoleon would not run the risk of arrest as a fugitive. Thanking all those who offered to help him to escape, he decided on a plan he had had in mind several days, which seemed to him to be the most worthy of him as having an element of greatness, namely to demand asylum from the British government. Maitland, the commander of the "Bellerophon," had let him know that the request would be well received. Thus Napoleon wrote his famous letter to the prince regent:—

"Your Royal Highness, Exposed to the factions which distract my country and to the enmity of the greatest powers of Europe, I have ended my political career, and I come, like Themistocles, to appeal to the hospitality of the British people. I put myself under the protection of their laws, and beg your royal highness, as the most powerful, the most determined and the most generous of my enemies, to grant me this protection."

The allies at this moment were in agreement on only one point of their treatment of Napoleon. There must be no new return from Elba, and it would be perhaps even easier to return from America. The victors, to tell the truth, did not know what to do with him, and every solution presented difficulties. Their secret hope was that he would commit suicide, or perish on his way, the victim of a "White Terror." Or they would have liked Louis XVIII. on his return to Paris to have him summarily tried, condemned and executed. "We wish," wrote Lord Liverpool to Castlereagh, "that the king of France would have Bonaparte shot or hanged. It would be the best end to the business." But no one wished to take the responsibility, and Louis XVIII. less than anyone else. And Alexander I. and Wellington were working to save Napoleon's life. So the fate of the man regarded as an outlaw, "outside human society," *hostis generis humani*, had still to be decided. By his surrender to England the "Corsican ogre" laid on her the task of custody which Lord Liverpool would willingly have left to others.

Louis XVIII., who had returned to Paris on July 9, was anxious for the matter to be settled as quickly as possible, without taking the odium on himself. He ordered the prefect of Rochefort to keep the ex-emperor on the frigate *La Saale*, and to give him up to Commander Maitland, on the latter's requisition. Napoleon thought it more dignified to surrender without waiting for summons or arrest. On July 15 wearing the green coat of the *chasseurs de la garde*, and the small hat, his favourite uniform, and that in which he is always popularly represented he went on board the "Bellerophon."

One wonders if he deceived himself as to his fate and believed that the British government would allow him to go to America, or to remain at liberty in England, which had always welcomed exiles and was looked on as a political asylum. He may have

remembered Paoli and Theodore, king of Corsica for a brief period, who had come to London, to die. Strangely enough there has been found among his papers a short literary exercise, an imaginary letter from Theodore asking Walpole for protection. In his school exercise books is also the phrase "Saint Helena, a little island."

The Voyage.—If Napoleon had hoped to remain at liberty he was undeceived when the "Bellerophon" arrived at Plymouth. Admiral Keith delivered to him, in the name of the British government a letter which informed "General Bonaparte" that in order to deprive him of further opportunities of disturbing the peace of Europe, it was necessary to restrain his personal liberty, and that to this end Saint Helena had been chosen as his future residence. He might take with him three companions, from among those who had accompanied him to England, and a surgeon. The emperor, on receipt of the letter, protested that he was the guest and not the prisoner of the British government, and that the rights of hospitality were being violated in his person. He then resigned himself, and set an example of stoicism to his followers. He did no more than put into writing the verbal protest which he had made to Admiral Keith.

Napoleon took with him into his captivity General Bertrand, a former grand marshal of the palace, Count Montholon, aide de camp, and General Gourgaud, and a civilian, the count de Las Cases. Countess Bertrand and Countess Montholon were of the party, as well as Las Cases the younger, and several servants. On Aug. 7 they embarked on the "Northumberland," commanded by Admiral Cockburn, and almost immediately set sail. The voyage lasted more than two months. Napoleon preserved his impassibility, even though the officers and crew had been ordered to refrain from paying him marks of respect, and he was addressed merely as "General." On arriving at Saint Helena Cockburn even said to General Bertrand, "I know of no emperor living in this island, nor of any person with a right to that position, having, as you say, travelled with me on the Northumberland."

Reading was Napoleon's chief distraction, during this long and monotonous voyage which was bearing him for ever from France and from his family. He had read to him from the *Encyclopædia Britannica* everything concerning Saint Helena and the countries near which the ship was passing. After a turn on deck he would lean against a gun, which the midshipmen soon called "the emperor's gun," and talk at length of his past life, telling stories of his career. Las Cases, who kept a journal was thus led to begin his *Memorial of Saint Helena*. Soon Napoleon himself decided to dictate his recollections, beginning with his Italian campaign.

Saint Helena.—On Sunday, Oct. 15 the "Northumberland" dropped anchor before Saint Helena. Napoleon looked through his glasses at the island which was to be his tomb, without, says Las Cases, showing the slightest emotion, and then worked as usual. They landed the next day. The dwelling intended for the prisoner was called Longwood, and, as it was in bad repair and not ready for his reception he stayed temporarily at the small house "The Briars," of which Las Cases says: "The Emperor Napoleon, who was once so powerful, and master of so many crowns, found himself reduced to a little hovel a few square feet in dimensions, with neither curtains, shutters, nor furniture. He had to sleep, dress, eat, work, live there, and if there was cleaning to be done he had to go out of doors." Napoleon protested more than once against this "infamous treatment," against the fact that he was treated as a prisoner of war, though he had himself taken refuge under the English flag, and against the prohibition of news of his wife and son. In December, Longwood was ready at last, and the little company moved there, together with Doctor O'Meara of the Northumberland who had asked to share Napoleon's exile, since no other doctor was available. He also has written an interesting account of the captivity.

Longwood, which had been a farm, was larger and a little more comfortable than "The Briars." Napoleon remained there till his death, spending his time in talking over his past career, dictating his reminiscences, reading, doing a little gardening, riding in the narrow limits permitted him, and even in learning English, which

he read fairly fluently, but would never speak. His chief troubles were the prohibition of correspondence with his family, and the badness of the food. His imprisonment became still more rigorous when, in April 1816, Admiral Cockburn was replaced by Hudson Lowe. The new Governor, obsessed with the fear of losing his prisoner, and, seeing nothing but espionage and plans of escape, made himself detested. Under his petty persecution Napoleon remembered with regret the régime of Admiral Cockburn. First Las Cases, accused of having organised a correspondence with the outer world, was deported to the Cape; O'Meara, the next to go, was replaced by the Corsican doctor, Antommarchi. In 1818 Gourgaud, who could not agree with his companions, left Saint Helena. Only Bertrand and Montholon stayed till the end.

Napoleon's health was suffering. It is possible that the climate, the food and mental anguish assisted the tendency towards cancer which he inherited from his father. His strength rapidly declined. In March 1821, he took to his bed. In April he dictated his will. "It is my wish," he said "that my ashes shall be laid to rest on the banks of the Seine among the French people whom I have loved so well." He added "I am dying before my time, murdered by the English oligarchy and its hired assassin" (Hudson Lowe). He died on the morning of May 5 in his 52nd year. His body was dressed in his favourite uniform, that of the *chasseurs de la garde*, and covered with the cloak he had worn at Marengo. He was buried in a lonely spot near a spring shaded by two weeping willows. He had often walked there. "Here lies" was on the stone. No name.

The Napoleonic Legend.—He had said one day, "What a romance my life has been." Napoleon knew mankind too well, he was in fact too great an artist not to realise that his captivity and his martyrdom gave him a magnificent opportunity of impressing himself upon posterity. On that lonely rock he was seized by an idea as great as were his plans of campaign or the *Code civil*. He would prepare, if not for himself, at least for someone of his race, something better than a return from Elba. He foresaw the nineteenth century, and would catch its imagination. Two thousand leagues away from France he divined the medley of sentiment and emotion forming there:—Austerlitz and Waterloo, the triumph and humiliation of the tricolor, the Revolution of 1789 ending in the return of the Bourbons, all the longings for liberty and for glory which would torture the people of France. Buried desires would rise again, resuscitated by regret and the magic of remembrance. Napoleon had always known how to appeal to the French people. He had not lost the art.

So the *Memorial of Saint Helena* was to become the Gospel of Saint Helena. During the hundred days he had already allied himself with the Liberals and the Republicans. The great Carnot had wept on his shoulder after the second abdication. He spent his years of exile in reviving the Napoleonic legend, in confounding it with liberalism, in "changing the eagle's plumage." He dreamed sometimes that he was working for himself, and that the people aroused by his promises would drive out their Kings and come to deliver him. "We are martyrs to an immortal cause," he said. "We struggle against oppression and the voice of the nations is for us."

In the conversations which were published to the world by his companions in captivity, he made himself the apostle of a new political doctrine, which, inspired by the principles of 1789, had the character and the fascination of a religion. It was a vast idealistic programme, a declaration of the rights and duties of the French people, a reshaping of Europe on the principles of liberty, equality, fraternity and justice. He identified his cause with that of universal freedom. The peoples must be set free, and a holy alliance of nations substituted for a holy alliance of Kings. "There are," he said "strivings for nationhood which must be satisfied sooner or later." No people should be left under the domination of another, and different sections of the same race, which wish to unite, ought not in the future to be separated. "Though they are scattered there are in Europe more than thirty million Frenchmen, fifteen million Spaniards, fifteen million Italians and thirty million Germans. I should like to have made each of these peoples a single united nation." He re-told his own

story, giving it a humanitarian and idealistic bias. He represented his dictatorship as that of a liberal, or "crowned Washington," a despot in spite of himself and for the world's good, waging war to found the United States of Europe. He called himself the Messiah of the Revolution whose name would be for the peoples "the emblem of their hopes."

This lofty incarnation triumphed. Popular imagination represented Napoleon at Saint Helena as on a sort of Mount Sinai. Béranger's songs, Victor Hugo's poems added to the glamour. In 1840 the government of Louis-Philippe obeyed the national will by sending the prince de Joinville to bring back the remains of the emperor. The "return of the ashes" was a historic day. Since then, Napoleon rests in the Invalides. Another poet, Lamartine, warned Louis-Philippe that this return foreshadowed another. And, indeed, thanks to the legend woven by his uncle, after the revolution of 1848, Louis Napoleon was elected president of the republic, and then restored the empire, accomplishing in foreign policy, by his support of Italian unity, the programme of nationalities, though the integration of Italy was not yet completed. Thus the Napoleon of Saint Helena survived.

THE NAPOLEONIC RECORD

The Soldier.—We must now briefly consider this man, whose personality was in every respect far above the mean, as a commander and as a legislator—as soldier and sovereign.

His master concepts may be gathered from his various sayings. "The art of war" he said "is simple and wholly executive. There is nothing ideological about it." And again "The whole art of war consists of a careful and well-thought out defensive, together with a swift and bold offensive." Simplicity and rapidity are the dominating features both of his campaigns and his battles. "The art of war" he said at the beginning of his career "consists, with inferior forces, in always having larger forces than the enemy at the point of attack or defence." To do this rapidity of movement is required. "Energy, rapidity" was his constant admonition to subordinates. One must concentrate one's own forces, keep them together, lead the enemy to give battle in the most unfavourable conditions; then, when his last reserves are engaged, destroy him by a decisive attack and end the war as quickly as possible.

As Napoleon himself said, all these precepts could be compressed in a very small book. He had, in fact, a method, not a system. "One of the characteristic features of Napoleonic strategy," says Marshal Franchet d'Espèrey, "is that, the goal once chosen and boldly chosen, the method does not vary, though, being supple, it adapts itself to circumstances." One might just as well say "the measure of the method is the commander's measure." Napoleon's power of rapidly summing up a situation and making his decision, explains his victories. As Clausewitz has well said: "On the field of battle everything depends on a decision made in a few minutes." Napoleon summed up everything, including himself, in the words: "No precise rules can be laid down. Everything depends on the character of the general, his abilities, his weakness, the quality of his troops, the range of their weapons, the weather and a thousand other circumstances which never repeat themselves." Hence before the battle his meticulous study of the position, of alternative suppositions, a keen examination of the psychology of his opponent, and the rigorous use of information, material and moral. The weak point was that everything depended on Napoleon. He saw everything, did everything, took account of the most insignificant details, himself directly gave all the orders. His lieutenants, having the habit of obedience, were merely executors who took no initiative. Berthier, although he held the position of chief of staff, said that he counted for nothing with the army. Therefore, an indisposition of the emperor was sufficient to disorganize the machine.

Then, from 1812 onwards, the number of troops involved became too large, and the commander's vision no longer sufficiently sure. It was a war of armies, not of army corps. The Napoleonic system began to give less favourable results. An exaggerated belief in his "star" and his genius, and his heavy demands on an exhausted France, explain the final catastrophe. He had long profited from the concentration of power in his own person. He

4. "Napoleon I," statue by Philippe-Laurent Roland. In the Paris Institut
5. House in the Place Letizia, Ajaccio, Corsica, in which Napoleon Bonaparte was born. From the drawing by Eric Pape
6. "Napoleon Crossing the Alps," by J. L. David. At Versailles
7. "Longwood," Napoleon's residence at St. Helena. Drawing by Harry Pena, from a photograph belonging to L. C. Billings

himself rejoiced in being almost the only great captain to hold absolute authority over a rich and populous country, and command its resources both of men and money. Yet in spite of his enormous intellectual energy he gave way in the end under the burden. He insisted on regulating the minutest details of his government. Thus the decree which still governs the *Théâtre Français* was signed at Moscow. Moreover his empire was precarious. Founded on victory and success, it could not survive defeat. Remembering after Waterloo Louis XIV. unshaken by misfortune, he said, "If I had been my own grandson, I could have retreated as far as the Pyrenees."

The Sovereign.—Yet he did more than win and lose battles. He gave to France laws which for the most part still endure. We have seen that when he became first consul, France had fallen practically into anarchy. The ancient laws, excessively complicated, because they differed from province to province and were customary and traditional, had been wiped out by the revolution. The new laws, so far as they existed at all, were too revolutionary in character and unadapted to normal society. The *code civil* united what in Roman law and in tradition was best suited to France under the conditions engendered by the Revolution. It may be said to be a systemization of good sense, at the same time logical and historical. Napoleon had no legal training, and his share in the work should not be exaggerated, but he intervened continually with the dominating idea that, though the work of the revolution must not be undone, order must be restored in France. Here again he profited by his lack of prejudice and his trained intelligence. He carried out the transition from old to new France. Probably he alone could have re-established the conditions necessary to settled government without being accused of relinquishing the "civil victories of the revolution." He was able to reimpose indirect taxation and in particular food taxes, the most unpopular of all, the abolition of which had made it impossible to place the finances of the Republic on a sound basis.

The council of state, the public accounts office, the courts of justice, the universities, the rights of the *Banque de France*, all these were established, counterbalancing the work of the revolutionary demagogues, and they serve to this day as restraining influences on the occasional over-violence of democracy. On the other side of the picture we see excessive centralization which stifled provincial life and local characteristics, cast the whole country in the same mould, and made the State supreme over the entire people—a system singularly favourable to "étatisme." Thus as a legislator, and as a legendary figure, Napoleon appeared as the restorer of order and authority and the embodiment of progress.

BIBLIOGRAPHY.—(I.) GENERAL. (A) *Sources.* The chief source is the *Correspondance* published by order of Napoleon III. (28 volumes, Paris 1857-59), followed by the *Œuvres de Napoléon à Sainte Hélène* (1870, 4 vols.). This is incomplete. There should also be consulted: *Lecestre, Lettres inédites de Napoléon Ier* (1897, 2 vol.); de Brotonne, *Idem* (1898) and *Dernières lettres inédites* (1903); A. Chuquet, *Ordres et apostilles* (1911-12, 4 vol.); Picard et Tuety, *Correspondance inédite* (1912-13, 4 vols.). The most complete itinerary has been given by Schnermann: *Itinéraire général de Napoléon Ier* (1908). For legal documents, see *Bulletin des lois*, 3rd and 4th series; Duvergier, *Collection* (vols. 12 to 18); Dalloz, *Répertoire* (1st ed. 1865-70—48 vols.). (B) *History.* Histories of the Napoleonic period are innumerable. The oldest, such as that of Sir Walter Scott, have little more than antiquarian interest. This is not the case with: Thiers, *Histoire du Consulat et de l'Empire* (1845-1862), 20 volumes with tables and maps. Numerous editions in all languages; Lanfrey, *Histoire de Napoléon Ier* (1867-75, 5 volumes); Oncken, *Das Zeitalter der Revolution des Kaiserreiches und der Befreiungskriege* (1880, 2 vol.); Taine, *Les origines de la France contemporaine*, 3rd part, *le Régime moderne* (1891-94—unfinished); A. Fournier, *Napoléon I. Eine Biographie* (Wien and Leipzig, 1886-1893, 3 vols.); Lavisse et Rambaud, *Histoire générale* (Vol. IX. 1893); Masson, *Napoléon et sa famille* (10 vol. 1897-1913); J. Holland Rose, *The Life of Napoleon I.* (1905, 2 vols.); *The Cambridge Modern History* (vol. IX., *Napoleon*, 1906); W. M. Sloane, *Life of Napoleon Bonaparte* (1910, biblog.); Lavisse, *Histoire de la France contemporaine* (Vols. II. and III. by G. Parlett, 1923); E. Ludwig, *Napoleon* (1927); Madelin, *Histoire politique 1815 to 1804* volume 4 of the *Histoire de la nation française*, by G. Hanotaux.

(II.) YOUTH AND TRAINING. (A) *Sources.* Napoleon's early works have been published by Masson and Biagi under the title *Napoleon inconnu* (1895, 2 vols.) but the editors have been charged with cor-

recting the text improperly. (B) *History.* Gadobert, *La jeunesse de Napoléon Ier* (1897); A. Chuquet, *La jeunesse de Napoléon Ier* (3 vol. 1897-99); P. Cottin, *Toulon et les Anglais en 1793* (1898); C. J. Fox, *Napoléon Bonaparte and the Siege of Toulon* (Washington, 1902); J. Colin, *L'éducation militaire de Napoléon Ier* (1902); O. Browning, *Napoleon, the First Phase* (1905); H. F. Hall, *Napoleon's Notes on English History* (1905); H. Zivy, *Le 13 vendémiaire* (1898).

(III.) FROM THE ITALIAN CAMPAIGN TO THE 18TH BRUMAIRE. (A) *Sources.* Here must be cited the memoirs of all the great figures of that time. There are in particular, those of the directors: the memoirs of Barras (ed. Duruy 1895-96 4 vols.); of Barthélemy, ed. Y. de Dampierre (1914); of Carnot, ed. his grandson; of Gohier (1824, 2 vols.); of La Revellière (1895, 3 vols.). See also the *Mémoires de Masséna*, ed. Koch (1849-50, 7 volumes). For the expedition to Egypt: *Les Mémoires de Bourienne* (Vols. II. and III. 1829); the *Lettres de Geoffroy Saint Hilaire*, ed. Hamy (1901); Volume III. of *Nelson's Despatches and Letters*. Under the title: *Paris pendant la réaction thermidorienne et le Directoire* Aulard has published many police reports and extracts from newspapers (5 vols. 1898-1902). (B) *History.* A. Sorel, *L'Europe et la Révolution française* (Vol. V. *Bonaparte et le Directoire*, 1903); Guyot, *Le Directoire et la paix de l'Europe* (1911); Clausewitz, *Der Feldzug von 1796 in Italien* (1883); Colin, *Etude sur la campagne de 1796-1797* (1818); Fabry, *Campagne d'Italie* (1900-01 3 vols.), followed by *Mémoires* (1905) and *Rapports* (1905), the whole edited by the historical section of the French General Staff; Gaffarel, *Bonaparte et les républiques italiennes, 1796-97* (1895); C. Tivaroni, *Storia critica del Risorgimento italiano* (first three vols., Turin 1888-97); Bianchi, *Storia della monarchia piemontese* (Turin 1885 4 vols. Vol. II.). The most recent and much the most satisfactory work on Egypt is La Jonquière, *L'expédition d'Égypte* (1900-07, 5 vols., ed. historical section of the General Staff). For the coup d'état, see Vandal, *L'avènement de Bonaparte* (Vol. I. 1903 with a critical indication as to its sources); J. Bainville, *Le 18 Brumaire* (1926); Rocquain, *L'état de la France au 18 Brumaire* (1874).

(IV.) THE PRIVATE LIFE OF NAPOLEON. (A) *Sources.* The principal memoirs are those of the Duchesse d'Abrantès (1831-37, 18 vols.); of Mme. de Remusat (1870-80, 3 vols.); the *Considérations and Dix années d'exil* of Mme. de Staël; the memoirs of various members of the staff of the palace, such as Beausset (1827-28, 4 vols.), Constant (1830-31, 6 vols.), Baron Fain (1908), General Durand (1819, 2 vols.) and Ménéval (1894, 3 vols.) etc. The work entitled *Mémoires et Correspondance de l'impératrice Joséphine* (1820) is apocryphal. See also *Empress Marie-Louise, Correspondance 1799-1847* (Vienna, 1887); Jérôme, *Mémoires et Correspondance*, ed. du Casse (1861-66, 7 vols.); Joseph, *Mémoires et Correspondance*, ed. du Casse (1853-54, 10 vols.); Queen Hortense, *Mémoires* (3 vols. 1927). (B) *History.* Frédéric Masson, *Napoléon et les femmes* (1893); *Napoléon chez lui* (1894); Bouchot, *La toilette à la cour de Napoléon* (1895); A. Lévy, *Napoléon intime* (1893); de Lescure, *Napoléon et sa famille* (1867); Larrey, *Madame Mère* (1892, 2 vols.); Masson, *Joséphine de Beauharnais, Madame Bonaparte, Joséphine impératrice, Joséphine répudiée* (1899-1919, 4 vols.); Rocquain, *Napoléon Ier et le Roi Louis* (1875); Welschinger, *Le divorce de Napoléon* (1899), *Le mariage de Napoléon* (*Revue révolutionnaire*, 1888, II.); Masson, *Maria-Louise* (1903); Masson, *Napoléon et son fils* (1904). See also BONAPARTE (Family).

(V.) FOREIGN POLICY AND WARS. (A) *Sources.* Martens, *Recueil général des traités d'alliance et de paix*, with appendices and tables (Göttingen, 1817-76); Talleyrand, *Lettres inédites à Napoléon*, ed. Pailain (1889), and *Mémoires*, ed. de Broglie (1891-92, 5 vols.); Metternich, *Mémoires* (8 vols., Vols. 1 and 2); Hardenberg, *Denkwürdigkeiten* (ed. Ranke, Leipzig, 1877, 5 vols.); Nesselrode, *Lettres et papiers* (Vols. III. to V. 1905-07); Castlereagh, *Memoirs and Correspondence* (1848-53, 12 vols.); Tratchevski, *Documents diplomatiques concernant les relations de la France et de la Russie* (St. Petersburg, 1890-91, 2 vols. in Russian and in French); Bailléul, *Preussen und Frankreich Dipl. Corr.* (Leipzig, 1881-87, 2 vols.). For the details of military events and the actual life of the armies we must have recourse to the memoirs of generals and soldiers, such as:—Bernadotte, *Correspondance* (1819); Davout, *Correspondance* (1887, 4 vols.); Gille, *Mémoires d'un conscrit* (1892); Lavallette, *Mémoires* (1831, 2 vols.); Colnet, *Cahiers* (1883); Marbot, *Mémoires* (1891-3 vols.); Marmont, *Mémoires* (1856-57, 9 vols.); Murat, *Correspondance, Lettres et documents* (1899 and 1908-14); Soult, *Mémoires* (1854, 3 vols.) etc. These memoirs are of unequal value, and should be accepted with considerable reserve. (B) *History.* Bourgeois, *Manuel historique de politique étrangère*, vol. II. (1898); Sorel, *L'Europe et la Révolution française* vols. VI. VII. et VIII. with tables (1903-04); Tramond, *Manuel d'histoire maritime de la France* (1916); A. T. Mahan, *Influences of Sea Power on the French Revolution and Empire* (1892 2 vols.); Driault, *Napoléon et l'Europe* (1910); Pingaud, *Bonaparte, président de la république italienne, La domination française dans l'Italie du Nord* (1914, 2 vols.); H. A. L. Fisher, *Napoleonic Statesmanship: Germany* (1903); Frohlevaux, "La politique coloniale de Napoléon" (*Revue des questions historiques*, 1901); A. Lévy, *Napoléon et la paix* (1903); Driault, *La politique orientale de Napoléon* (1904); Marshal Franchet d'Espèrey and General Mangin, *Histoire militaire et navale* (Vol. VIII. of the *Histoire de la nation française* de Hanotaux).

For the details of military and diplomatic events:—Roberts: "The negotiations preceding the peace of Amiens" (*Transactions of the Royal Hist. Soc.* 1901 Vol. XX.); H. M. Bowman, *Preliminary Stages of the Peace of Amiens* (Toronto 1900); Philipson, "La Paix d'Amiens" (*Revue historique* 1901); O. Browning, *England and Napoleon in 1803* (1887); J. H. Rose, "Napoleon and English Commerce" (*Engl. Hist. Rev.* 1893); *Select Despatches . . . relating to the Formation of the Third Coalition* (1904); Coquelle, *Napoléon et l'Angleterre* (1904); O. Brandt, *England und die napoleonische Weltpolitik 1800-3* (Heidelberg 1916); Yorck von Wartenburg, *Napoleon als Feldherr* (1885-86 2 vols.); Camon: *La guerre napoléonienne: Précis des campagnes* (1903), *les Systèmes d'opérations* (1907), *les Batailles* (1910), *la Fortification* (1914); and, always interesting Jomini: *Vie politique et militaire de Napoléon Ier* (1827 4 vols. and maps); Mathieu Dumas, *Précis des événements militaires* (1817-26 19 vols.); Roche, *Die Kontinentalperre* (Nauwbourg 1894); Oman, *History of the Peninsula War* (1902-11 4 vols.); Greillon, *Les guerres d'Espagne* (1902); Fabry, *Campagne de Russie* (1900-03, 5 vols.); Chuquet, *La guerre de Russie* (1912 3 vols.); Clement, *Campagne de 1813* (1904); Houssaye, *1814* (1 vol. 1888), *1815* (3 vols. 1895-1905); Fournier, *Der Kongress von Chatillon* (Leipzig, 1900); P. Gruyer, *Napoléon roi de Pile d'Elbe* (1906).

(VI.) INTERNAL POLITICS. (A) *Sources*. Contemporary memoirs already cited; Aulard, *Paris sous le Consulat* (4 vols.), *Paris sous le premier Empire* (Vols. I. and II.) (unfinished), a collection of police reports and newspaper articles; Gaudin, duke of Gæta: *Mémoires, Souvenirs, Opinions et Ecrits* (new edition in 3 vols., 1926); Portalis, *Discours et travaux sur le Code Civil* (1844); Pasquier, *Histoire de mon temps* (1893-95 6 vols.); Boulay de la Meurthe: *Documents sur la négociation du Concordat et sur les autres rapports de la France avec le Saint-Siège* (1891-1905 6 vols.); Villemain, *Rapport au roi sur l'instruction secondaire* (1843 in 4°); Cousin, *Défense de l'Université* (Discours, 1844); Pelet de la Lozère, *Opinions de Napoléon sur divers sujets de politique et d'administration* (1833). (B) *History*: Vandal, *L'avènement de Bonaparte* (2 vols. 1905); Esmein, *Précis élémentaires du droit français* (1908); Aucoc: *Le Conseil d'Etat* (1876); L. Madelin, *Fouché* (1901 2 vols.); E. Mousset, *Histoire de l'administration provinciale, départementale et communale* (1885); Régnier, *Les Préfets du Consulat et de l'Empire* (1907); Passy, *Fréchet, préfet de la Seine* (1867); Dejean, *Beugnot* (1907); Pingaud, *Jean de Bry, préfet de Besançon* (1909); Levy Schneider, *Jean Bon Saint André, préfet de Mayence* (Vol. II. 1901); Stourm, *Les finances du Consulat* (1902); Marion, *Histoire financière* Vol. IV. (1797, 1925), a first class piece of work; A. Madelin, *Le premier Consul législateur* (1865), *Livre du Centenaire de la Cour des Comptes*; Schmidt, *L'organisation de l'Université Impériale* (Ecole des Hautes Etudes Sociales, 1912, *La lutte scolaire*). (C) *On the Concordat and Religious Questions*: Abbé Mounet, *Histoire générale de l'Eglise*, Vol. VII. (1916); Debidour, *Histoire des rapports de l'Eglise et de l'Etat* 1898; Rinieri, *La diplomazia pontificale nel secolo XIX. Vol. I.* (Rome 1902 Fr. tr. Verdier 1903); d'Haussonville: *L'Eglise romaine et le premier Empire* (1868-69, 5 vols.). (D) *On the opposition and the various plots*: E. (J. BAL.)

NAPOLEON II.: see REICHSTADT, JOSEPH CHARLES, DUKE OF.

NAPOLEON III. [CHARLES LOUIS NAPOLEON BONAPARTE] (1808-1873), emperor of the French, was born on April 20, 1808, in Paris at 8 rue Cerutti (now rue Laffitte), and not at the Tuileries, as the official historians state. He was the third son of Louis Bonaparte (see BONAPARTE), brother of Napoleon I., and king of Holland (1806-10), and of HORTENSE DE BEAUHARNAIS (q.v.). Of the two other sons of Louis Bonaparte and Hortense, the elder, Napoleon Charles (1802-1807), died in infancy; the second, Napoleon Louis (1804-1831), died in the insurrection of the Romagna, leaving no children.

Exile of Hortense.—After Waterloo, Hortense, suspected by

the Bourbons of having arranged the return from Elba, had to go into exile. The ex-king Louis, who now lived at Florence, had compelled her by a scandalous law-suit to give up to him the elder of her two children. With her remaining child she wandered, under the name of duchesse de Saint-Leu, from Geneva to Aix, Carlsruhe and Augsburg. In 1817 she bought the castle of Arenenberg, in the canton of Thurgau, on a wooded hill looking over the Lake of Constance. Hortense supervised her son's education in person. The young prince also studied at the gymnasium at Augsburg, and there he acquired his slight German accent.

In 1823 he accompanied his mother to Italy, visiting his father at Florence, and his grandmother Letitia at Rome, and dreaming with Le Bas on the banks of the Rubicon. He returned to Arenenberg to complete his military education under Colonel Armandi and Colonel Dufour, who instructed him in artillery and military engineering. At the age of twenty he was a "Liberal," an enemy of the Bourbons and of the treaties of 1815; but he was dominated by the cult of the emperor, and for him the liberal ideal was confused with the Napoleonic.

Revolution of 1830.—The July revolution of 1830, of which he heard in Italy, roused all his young hopes. He could not return to France, for the law of 1816 banishing all his family had not been abrogated. But the liberal revolution knew no frontiers. Italy shared in the agitation. He had already met some of the conspirators at Arenenberg, and it is practically established that he now joined the associations of the Carbonari. Following the advice of his friend the Count Arese and of Menotti, he and his brother were among the revolutionaries who in February 1831 attempted a rising in Romagna and the expulsion of the pope from Rome. They distinguished themselves at Civita Castellana, a little town which they took; but the Austrians arrived in force, and during the retreat Napoleon Louis, the elder son, took cold, followed by measles, of which he died. Hortense hurried to the spot and took steps which enabled her to save her second son from the Austrian prisons. He escaped into France, where his mother, on the plea of his illness, obtained permission from Louis Philippe for him to stay in Paris. But he intrigued with the republicans, and Casimir-Périer insisted on the departure of both mother and son. In May 1831 they went to London, and afterwards returned to Arenenberg.

For a time he thought of responding to the appeal of some of the Polish revolutionaries, but Warsaw succumbed (September 1831) before he could set out. Moreover the plans of this young and visionary *enfant du siècle* were becoming more definite. The duke of Reichstadt died in 1832. His uncle, Joseph, and his father, Louis, showing no desire to claim the inheritance promised them by the constitution of the year XII., Louis Napoleon henceforth considered himself as the accredited representative of the family. He endeavoured to define his ideas, and in 1833 published his *Réveries politiques, suivies d'un projet de constitution*, and *Considérations politiques et militaires sur la Suisse*; in 1836, as a captain, in the Swiss service, he published a *Manuel d'artillerie*, in order to win popularity with the French army.

Strasbourg Conspiracy.—With the aid of his friend Fialin and of Eléonore Gordon, a singer, and of certain officers, such as Colonel Vaudrey, an old soldier of the Empire, commanding the 4th regiment of artillery, and Lieutenant Laity, he tried to bring about a revolt of the garrison of Strasbourg (Oct. 30, 1836). The conspiracy was a failure, and Louis Philippe, fearing lest he might make the pretender popular either by the glory of an acquittal or the aureole of martyrdom, had him taken to Lorient and put on board a ship bound for America, while his accomplices were brought before the court of assizes and acquitted (February 1837). The prince was set free in New York in April; by the aid of a false passport he returned to Switzerland in August, in time to see his mother before her death on Oct. 3, 1837.

At any other time this attempt would have covered its author with ridicule. Such, at least, was the opinion of the whole of the family of Bonaparte. But his confidence was unshaken, and in the woods of Arenenberg the romantic-minded friends who remained faithful to him still honoured him as emperor. And now the government of Louis Philippe, by an evil inspiration, began to

act in such a way as to make him popular. In 1838 it caused his partisan Lieutenant Laity to be condemned by the Court of Peers to five years' imprisonment for a pamphlet which he had written to justify the Strasbourg affair; then it demanded the expulsion of the prince from Switzerland, and when the Swiss government resisted, threatened war. Having allowed the July monarch to commit himself, Louis-Napoleon at the last moment left Switzerland voluntarily. All this served to encourage the mystical adventurer. In London, where he had taken up his abode, together with Arese, Kialin (says Persigny), Doctor Conneau and Vaudrey, he was at first well received in society, being on friendly terms with Count d'Orsay and Disraeli, and frequenting the *salon* of Lady Blessington. He was evolving his programme of government, and in 1839 wrote and published his book: *Des Idées napoléoniennes*, a curious mixture of Bonapartism, socialism and pacificism, which he represented as the tradition of the First Empire. He also noted the fluctuations of French opinion.

Boulogne Conspiracy.—The pretender, again thinking that the moment had come, formed a fresh conspiracy in 1840. With a little band of fifty-six followers he attempted to provoke a rising of the 42nd regiment of the line at Boulogne, hoping afterwards to draw General Magnan to Lille and march upon Paris. The attempt was made on Aug. 6, but failed; he saw several of his supporters fall on the shore of Boulogne, and was arrested together with Montholon, Persigny and Conneau. This time he was brought before the Court of Peers with his accomplices; he entrusted his defence to Berryer and Marie, and took advantage of his trial to appeal to the supremacy of the people, which he alleged, had been disregarded, even after 1830. He was condemned to detention for life in a fortress, his friend Aladenize being deported, and Montholon, Parquin, Lombard and Fialin being each condemned to detention for twenty years. On Dec. 15, the very day that Napoleon's ashes were deposited at the Invalides, he was taken to the fortress of Ham. On the whole the régime imposed upon him was mild. He corresponded with Louis Blanc, George Sand and Proudhon, and collaborated with the journalists of the Left, Degorge, Peauger and Souplet. For six years he worked very hard "at his University of Ham," as he said. He wrote some *Fragments historiques*, studies on the sugar-question, on the construction of a canal through Nicaragua, and on the recruiting of the army, and finally, in the *Progrès du Pas-de-Calais*, a series of articles on social questions which were later embodied in his *Extinction du paupérisme* (1844). But the same persistent idea underlay all his efforts. On May 25, 1846, he escaped to London, giving as the reason for his decision the dangerous illness of his father. On July 27 his father died.

Return to France.—He was again well received in London and he "made up for his six years of isolation by a furious pursuit of pleasure." The duke of Brunswick and the banker Ferrère interested themselves in his future, and gave him money, as did also Miss Howard, whom he later made comtesse de Beauregard, after restoring to her several millions. At the first symptoms of revolutionary disturbance he returned to France; on Feb. 25, he offered his services to the Provisional Government, but, on being requested by it to depart at once, resigned himself to this course. But Persigny, Mocquard and all his friends devoted themselves to an energetic propaganda in the press, by pictures and by songs. After May 15 had already shaken the strength of the young republic, he was elected in June 1848 by four departments, Seine, Yonne, Charente-Inférieure and Corsica. In spite of the opposition of the executive committee, the Assembly ratified his election. But he had learnt to wait. He sent in his resignation from London, merely hazarding this appeal: "If the people impose duties on me, I shall know how to fulfil them." This time events worked in his favour; the industrial insurrection of June made the middle classes and the mass of the rural population look for a saviour, while it turned the industrial population towards Bonapartism, out of hatred for the republican *bourgeois*.

Presidency of the Republic.—On Sept. 26 he was re-elected by the same departments; on Oct. 11 the law decreeing the banishment of the Bonapartes was abrogated; on the 26th he made a speech in the Assembly defending his position as a pretender,

and cut such a sorry figure that Antony Thouret contemptuously withdrew the amendment by which he had intended to bar him from rising to the presidency. Thus he was able to be a candidate for this formidable power. The former rebel of the Romagna, the Liberal *Carbonaro*, was henceforth to be the tool of the priests. In his very triumph appeared the ultimate cause of his downfall. On Dec. 10 he was elected president of the Republic by 5,434,226 votes against 1,448,107 given to Cavaignac. On Dec. 20, he took the oath "to remain faithful to the democratic Republic . . . to regard as enemies of the nation all those who may attempt by illegal means to change the form of the established government." From this time onward his history is inseparable from that of France. But, having attained to power, he still endeavoured to realize his cherished project. All his efforts (Dec. 10, 1848 to Dec. 2, 1852) tended towards the acquisition of absolute authority, which he wished to obtain, ostensibly from the people.

It was with this end in view that he co-operated with the party of order in the expedition to Rome for the destruction of the Roman republic and the restoration of the pope (March 31, 1849), and afterwards in all the reactionary measures against the press and the clubs, and for the destruction of the Reds. But in opposition to the party of order, he defined his own personal policy. "The name of Napoleon," he said on this occasion, "is in itself a programme; it stands for order, authority, religion and the welfare of the people in internal affairs, and in foreign affairs for the national dignity."

In spite of this alarming assertion of his personal policy, he still remained in harmony with the Assembly (the Legislative Assembly, elected on May 28, 1849) in order to carry out "a Roman expedition at home," i.e., to clear the administration of all republicans, put down the press, suspend the right of holding meetings and, above all, to hand over education to the Church. But he knew where to stop and how to keep up a show of democracy. When the Assembly, by the law of May 31, 1850, restricted universal suffrage and reduced the number of the electors from 9 to 6 millions, he was able to throw upon it the whole responsibility for this *coup d'état bourgeois*.

In fact, while trying to compass the destruction of the republican movement of the Left, he was taking careful steps to win classes. At his side were his accomplices, men ready for anything, whose only hopes were bound up with his fortunes, such as Morny and Rouher; his paid publicists, such as Romieu, the originator of the "red spectre"; his cudgel-bearers, the "Ratapoils" immortalized by Daumier, who terrorized the republicans.

Coup d'état.—He next entered upon that struggle with the Assembly, now discredited, which was to reveal to all the necessity for a change, and a change in his favour. In January 1851 he deprived Changarnier of his command of the garrison of Paris. "The Empire has come," said Thiers. The pretender would have preferred, however, that it should be brought about legally, the first step being his re-election in 1852. The Constitution forbade his re-election; therefore the Constitution must be revised. On the 19th of July the Assembly threw out the proposal for revision, thus signing its own death-warrant, and the *coup d'état* was resolved upon. He prepared for it systematically. The cabinet of Oct. 26, 1851 gave the ministry for war to his creature Saint-Arnaud. All the conspirators were at their posts—Maupas at the prefecture of police, Magnan at the head of the troops in Paris. At the Elysée, Morny, adulterine son of Hortense, a hero of the Bourse and successful gambler, supported his half-brother by his energy and counsels. The ministry proposed to abrogate the electoral law of 1850, and restore universal suffrage; the Assembly by refusing made itself still more unpopular. By proposing to allow the president of the Assembly to call in armed force, the questors revealed the Assembly's plans for defence, and gave the Elysée a weapon against it ("donnent barre contre elle à l'Elysée"). The proposition was rejected (November 17), but Louis-Napoleon saw that it was time to act. On Dec. 2 he carried out his *coup d'état*.

Proclamation as Emperor.—But affairs developed in a way which disappointed him. By dismissing the Assembly, by offering the people "a strong government," and re-establishing "a France

regenerated by the Revolution of '89 and organized by the emperor," he had hoped for universal applause. But both in Paris and the provinces he met with the resistance of the Republicans, who had reorganized in view of the elections of 1852. He struck at them by mixed commissions, deportations and the whole range of police measures. The *décrets-lois* of the year 1852 enabled him to prepare the way for the new institutions. On Dec. 2, 1852 he became in name what he was already in deed, and was proclaimed Emperor of the French.

The aim which the emperor had in view was, by a concentration of power which should make him "the beneficent motive force of the whole social order" (constitution of the 14th of January 1852; administrative centralization; subordination of the elected assemblies; control of the machinery of universal suffrage) to unite all classes in "one great national party" attached to the dynasty. His success, from 1852 to 1856, was almost complete. The nation was submissive, and a few scattered plots alone showed that republican ideas persisted among the masses. As "restorer of the overthrown altars," he won over the "men in black," among them Veuillot, editor-in-chief of *l'Univers*, and allowed them to get the University into their hands. By the aid of former Orleanists, such as Billault, Fould and Morny, and Saint-Simonians such as Talabot and the Pereires, he satisfied the industrial classes, extended credit, developed means of communication, and gave a strong impetus to the business of the nation. By various measures, such as subsidies, charitable gifts and foundations, he endeavoured to show that "the idea of improving the lot of those who suffer and struggle against the difficulties of life was constantly present in his mind." His was the government of cheap bread, great public works and holidays. The imperial court was brilliant. The emperor, having failed to obtain the hand of a Vasa or Hohenzollern, married, on Jan. 29, 1853, Eugénie de Montijo, comtesse de Teba, aged twenty-six and at the height of her beauty.

Foreign Policy.—France was "satisfied" in the midst of order, prosperity and peace. The foreign policy of the Catholic party, by the question of the Holy Places and the Crimean War (1853-1856), gave him the opportunity of winning the glory which he desired, and the British alliance enabled him to take advantage of it. In January 1856 he had the good fortune to win a diplomatic triumph over the new tsar, Alexander II. It was at Paris (February 25-March 30) that the conditions of peace were settled. The emperor was now at the height of his power. He appeared to the people as the avenger of 1840 and 1815, and the birth to him of a son, Eugène Louis Jean Joseph, on March 16, 1856, assured the future of the dynasty. It was then that, strong in "the esteem and admiration with which he was surrounded," and "foreseeing a future full of hope for France," he dreamed of realizing the Napoleonic ideal in its entirety. This disciple of the German philologists, this crowned *Carbonaro*, the friend of the archaeologists and historians who were to help him to write the *Histoire de César*, dreamed of developing the policy of nationalism, and of assisting the peoples of all countries to enfranchise themselves.

From 1856 to 1858 he devoted his attention to the Rumanian nationality, and supported Alexander Cuza. But it was above all the deliverance of Italy which haunted his imagination. But the Catholics feared that the Italian national movement, when once started, would entail the downfall of the papacy; and in opposition to the emperor's Italian advisers, Arèse and Prince Jerome Napoleon, they pitted the empress, who was frivolous and capricious, but an ardent Catholic. Napoleon III. was under his wife's influence, and could not openly combat her resistance. It was the Italian Orsini who, by attempting to assassinate him as a traitor to the Italian nation on Jan. 14, 1858, gave him an opportunity to impose his will indirectly by convincing his wife that in the interests of his own security he must "do something for Italy." Events followed each other in quick succession, and now began the difficulties in which the Empire was to be irrevocably involved. Not only did the Italian enterprise lead to strained relations with Great Britain, the alliance with whom had been the emperor's chief support in Europe, and compromised its credit; but the claims of parties and classes again began to be heard at home.

The Italian war aroused the opposition of the Catholics. After Magenta (June 4, 1859), it was the fears of the Catholics and the messages of the empress which, even more than the threats of Prussia, checked him in his triumph and forced him into the armistice of Villafranca (July 11, 1859). But the spread of the Italian revolution and the movement for annexation forced him again to intervene. He appealed to the Left against the Catholics by the amnesty of April 17, 1859. His consent to the annexation of the Central Italian states, in exchange for Savoy and Nice (Treaty of Turin, March 24, 1860) exposed him to violent attacks on the part of the ultramontanes, whose slave he had practically been since 1848. At the same time, the free-trade treaty with Great Britain (January 5, 1860) aroused a movement against him among the industrial *bourgeoisie*.

From this time onward, in face of a growing opposition, anxiety for the future of his régime paralysed his initiative. Placed between his Italian counsellors and the empress, he was ever of two minds. His plans for remodelling Europe had a certain generosity and grandeur; but internal difficulties forced him into endless manoeuvre and temporization, which led to his ruin. Thus in October 1862, after Garibaldi's attack on Rome, the clerical coterie of the Tuileries triumphed. But the replacing of M. Thouvenel by M. Drouin de Lhuys did not satisfy the more violent Catholics, who in May 1863 joined the united opposition. Thirty-five opposers of the government were appointed, Republicans, Orleanists, Legitimists or Catholics. The emperor dismissed Persigny, and summoned moderate reformers such as Duruy and Béhic. But he was still possessed with the idea of settling his throne on a firm basis, and uniting all France in some glorious enterprise which should appeal to all parties equally, and "group them under the mantle of imperial glory." From January to June 1863 he sought this appearance of glory in Poland, but only succeeded in embroiling himself with Russia. Then, after Syria and China, it was the "great inspiration of his reign," the establishment of a Catholic and Latin empire in Mexico, enthusiasm for which he tried in vain from 1863 to 1867 to communicate to the French.

But while the strength of France was wasting away at Puebla in Mexico, Bismarck was founding German unity. In August 1864 the emperor, held back by French public opinion, which was favourable to Prussia, and by his idea of nationality, allowed Prussia and Austria to seize the duchies of Schleswig and Holstein. After his failure in Poland and Mexico and in face of the alarming presence of Germany, only one alliance remained possible for Napoleon III., namely with Italy. He obtained this by the convention of the 15th of September 1864 (involving the withdrawal of the French troops from Rome). But the Catholic party redoubled its violence, and the pope sent out the encyclical *Quanta Cura* and the *Syllabus*, especially directed against France. In vain the emperor sought in German affairs a definitive solution of the Italian question. At Biarritz he prepared with Bismarck the Franco-Prussian alliance of April 1866; and hoped to become arbiter in the tremendous conflict which was about to begin. But Königgrätz came as a bolt from the blue to ruin his hopes. French interests called for an immediate intervention. But he resigned himself to the annexation by Prussia of northern Germany. "Now," said M. Drouin de Lhuys, "we have nothing left but to weep."

The Third Party.—Henceforth the brilliant dream, a moment realized, the realization of which he had thought durable, was at an end. The Empire had still an uncertain and troubled brilliancy at the Exhibition of 1867. But Berezowski's pistol shot, which accentuated the estrangement from the tsar, and the news of the death of Maximilian at Queretaro, cast a gloom over the later fêtes. In the interior the industrial and socialist movement, born of the new industrial development, added fresh strength to the Republican and Liberal opposition. The moderate Imperialists felt that some concessions must be made to public opinion. In opposition to the absolutist "vice-emperor" Rouher, whose influence over Napoleon had become stronger and stronger since the death of Morny, Émile Ollivier grouped the Third Party. Anxious, changeable and distraught, the emperor made the Liberal

concessions of Jan. 19, 1867 (right of interpellation), and then, when Ollivier thought that his triumph was near, he exalted Rouher (July) and did not grant the promised laws concerning the press and public meetings till 1868. The opposition gave him no credit for these tardy concessions. There was an epidemic of violent attacks on the emperor; the publication of the *Lanterne* and the Baudin trial, conducted by Gambetta, were so many death-blows to the régime. The *Internationale* developed its propaganda. The election of May 1869 resulted in 4,438,000 votes given for the government, and 3,355,000 for the opposition, who also gained 90 representatives. The emperor, disappointed and hesitating, was slow to return to a parliamentary régime. It was not till December that he instructed Ollivier to "form a homogeneous cabinet representing the majority of the Corps Législatif" (ministry of the 2nd of January 1870). But, embarrassed between the *Arcadiens*, the partisans of the absolute régime, and the republicans, Ollivier was unable to guide the Empire in a constitutional course. At the Tuileries Rouher's counsel still triumphed. It was he who inspired the ill and wearied emperor, now without confidence or energy, with the idea of resorting to the *plébiscite*. "To do away with the risk of a revolution," "to place order and liberty upon a firm footing," "to ensure the transmission of the crown to his son," Napoleon III. again sought the approbation of the nation. He obtained it with brilliant success, for the last time, by 7,358,786 votes against 1,571,939, and his work now seemed to be consolidated.

War With Prussia.—A few weeks later it crumbled irrevocably. Since 1866 he had been pursuing an elusive appearance of glory. Since 1866 France was calling for "revenge." He felt that he could only rally the people to him by procuring them the satisfaction of their national pride. Hence the mishaps and imprudences of which Bismarck made such an insulting use. Hence the negotiations of Nikolsburg, the "note d'aubergiste" (inn-keeper's bill) claiming the left bank of the Rhine, which was so scornfully rejected; hence the plan for the invasion of Belgium (August 1866), the Luxemburg affair (March 1867), from which M. de Moustier's diplomacy effected such a skilful retreat; hence the final folly which led his government into the war with Prussia (July 1870).

The war was from the first doomed to disaster. It might perhaps have been averted if France had had any allies. But Austria, a possible ally, could only join France if satisfied as regards Italy; and since Garibaldi had threatened Rome (Mentana, 1867), Napoleon III., yielding to the anger of the Catholics, had again sent troops to Rome. Negotiations had taken place in 1869. The emperor, bound by the Catholics, had refused to withdraw his troops. It was as a distant but inevitable consequence of his agreement of December 1848 with the Catholic party that in 1870 the emperor found himself without an ally.

His energy was now completely exhausted. Successive attacks of stone in the bladder had ruined his physique; while his hesitation and timidity increased with age. The influence of the empress over him became supreme. On leaving the council in which the war was decided upon the emperor threw himself, weeping, into the arms of Princess Mathilde. The empress was delighted at this war, which she thought would secure her son's inheritance.

Deposition.—On July 28 father and son set out for the army. They found it in a state of utter disorder, and added to the difficulties by their presence. The emperor was suffering from stone and could hardly sit his horse. After the defeat of Reichshoffen, when Bazaine was thrown back upon Metz, he wished to retreat upon Paris. But the empress represented to him that if he retreated it would mean a revolution. An advance was decided upon which ended in Sedan. On Sept. 2 Napoleon III. surrendered with 80,000 men, and on the 4th of September the Empire fell. He was taken as a prisoner to the castle of Wilhelmshöhe, near Cassel, where he stayed till the end of the war. After the intrigues of Bazaine, of Bismarck, and of the empress, the Germans having held negotiations with the Republic, he was *de facto* deposed. On March 1, the assembly of Bordeaux confirmed this deposition, and declared him "responsible for the

ruin, invasion and dismemberment of France."

Restored to liberty, he retired with his wife and son to Chislehurst in England. Unwilling even now to despair of the future, he still sought to rally his friends for a fresh propaganda. He had at his service publicists such as Cassagnac, J. Amigues and Hugelmann. He himself also wrote unsigned pamphlets justifying the campaign of 1870. It may be noted that, true to his ideas, he did not attempt to throw upon others the responsibility which he had always claimed for himself. He dreamed of his son's future. But he no longer occupied himself with any definite plans. He interested himself in pensions for workmen and economical stores. At the end of 1872 his disease became more acute, and a surgical operation became necessary. He died on Jan. 9, 1873, leaving his son in the charge of the empress and of Rouher. The young prince was educated at Woolwich from 1872 to 1875, and in 1879 took part in the English expedition against the Zulus in South Africa, in which he was killed. By his death vanished all hope of renewing the extraordinary fortune which for twenty years placed the descendant of the great emperor, the *Carbonaro* and dreamer, at once obstinate and hesitating, on the throne of France.

BIBLIOGRAPHY.—The *Oeuvres* of Napoleon III. have been published in four volumes (1854-57) and his *Histoire de Jules César* in two volumes (1865-69); this latter work has been translated into English by T. Wright. See also Ebeling, *Napoleon III. und sein Hof* (1891-94); H. Thirria, *Napoleon III. avant l'Empire* (1895); Sylvain-Blot, *Napoleon III.* (1899); Girardeau, *Napoleon III. intime* (1895); Sir W. A. Fraser, *Napoleon III.* (London, 1895); A. Ollivier, *L'Empire libéral* (14 vols., 1895-1909).

NAPOLEON, a village of north-western Ohio, U.S.A., on the Maumee river and Federal highway 24, 36 m. S.W. of Toledo; county seat of Henry county. It is served by the Detroit, Toledo and Ironton and the Wabash railways. Pop. (1920) 4,143 (94% native white). It is the trade centre of a grain-growing district, a railway division point, and has a number of factories.

NAPOLEON, a round game of cards (known colloquially as "nap"). Any number may play. The cards rank as at whist, and five are dealt to each player. The deal being completed, the player to the dealer's left looks at his hand and declares how many tricks he would play to win against all the rest, the usual rule being that more than one must be declared; in default of declaring he says "I pass," and the next player has a similar option of either declaring to make more tricks or passing, and so on all round. A declaration of five tricks is called "going nap." The player who declares to make most has to try to make them, and the others, but without consultation, to prevent him. The declaring hand has the first lead, and the first card he leads makes the trump suit. The players, in rotation, must follow suit if able. If the declarer succeeds in making at least the number of tricks he stood for he wins whatever stakes are played for; if not he loses. If the player declaring nap wins he receives double stakes all round; if he loses he only pays single stakes all round. Sometimes, however, a player is allowed to go "Wellington" over "nap," and even "Blücher" over "Wellington." In these cases the caller of "Wellington" wins four times the stake and loses twice the stake, the caller of "Blücher" receives six times and loses three times the stake. Sometimes a player is allowed to declare *misère*, i.e., no tricks. This ranks, as a declaration, between three and four, but the player pays a double stake on three, if he wins a trick, and receives a single on three if he takes none.

NAPOLEONIC CAMPAIGNS. The era of the Revolutionary and Napoleonic Wars falls into two main divisions, the first of which (1792-1801) is dealt with under the heading FRENCH REVOLUTIONARY WARS. In the present article are described the campaigns in central and eastern Europe, directed by Napoleon—no longer one amongst many French generals, nor even a simple *primus inter pares*, but "Emperor" in the fullest sense—between the years 1805 and 1814. Napoleon's short

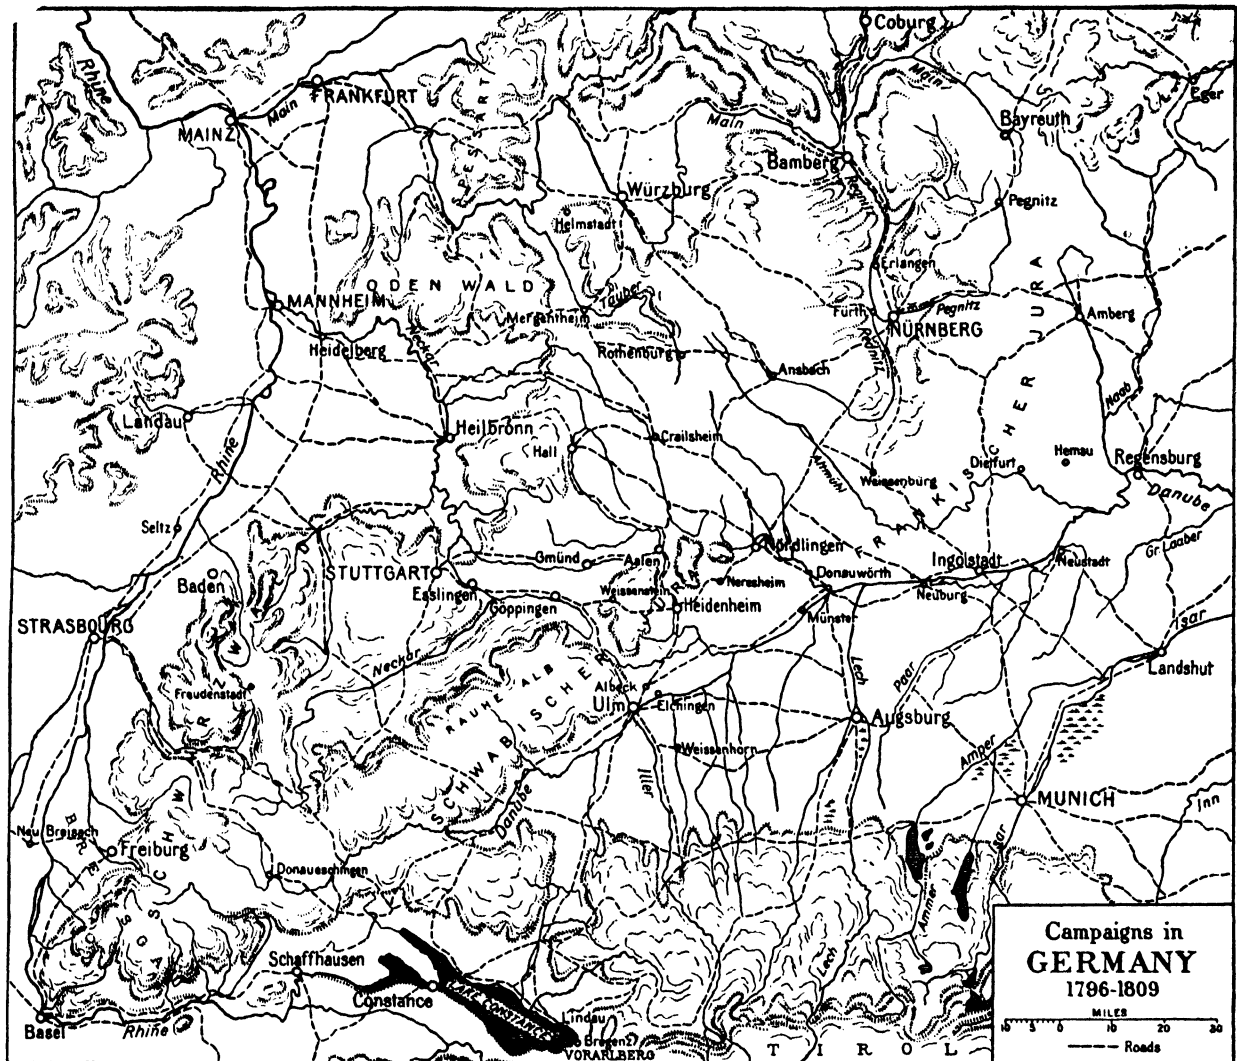

FIG. 1

Spanish Campaign of 1809 is dealt with under **PENINSULAR WAR** (this article covering the campaigns in Spain, Portugal and southern France 1808-1814), and for a discussion of the events that led to the final drama of Waterloo the reader is referred to **WATERLOO CAMPAIGN**.

The campaigns described below are therefore—

- (a) The Austrian War of 1805 (Ulm and Austerlitz).
- (b) The Conquest of Prussia and the Polish Campaign (Jena, Auerstädt, Eylau and Friedland).
- (c) The Austrian war of 1809 (Eckmühl, Aspern and Wagram).
- (d) The Russian War of 1812 (Borodino and the retreat from Moscow).
- (e) The German "War of Liberation," culminating in the Battle of the Nations around Leipzig.
- (f) The last campaign in France, 1814.

The naval history of 1803-1815 includes the culmination and the sequel of the struggle for command of the sea which began in 1793 and continued for more than a decade with results increasingly disappointing to the ambitions of Napoleon, finally reaching a decisive climax on the day of Trafalgar.

THE CAMPAIGN OF 1805

This may be regarded as a measure of self-defence forced upon Napoleon by the alliance of Russia (April 11), Austria (August 9)

and other powers with Great Britain. The possibility had long been before the emperor, and his intention in that event to march straight on Vienna by the valley of the Danube is clearly indicated in his reply (November 27, 1803) to a Prussian proposal for the neutralization of the South German states. In this he says, "It is on the road from Strasbourg to Vienna that the French must force peace on Austria, and it is this road which you wish us to renounce." When, therefore, on Aug. 25, 1805, he learnt definitely that Villeneuve (see *Naval Operations* below) had failed in his purpose of securing the command of the Channel, which was the necessary preliminary to the invasion of England, it was but the affair of a few hours to dictate the dispositions necessary to transfer his whole army to the Rhine frontier as the first step in the march which he had determined to make to the Danube. On the date of this decision the army actually lay in the following positions:—

I. Corps	Bernadotte	Hanover (Göttingen)
II. "	Marmont	Holland
III. "	Davout	Camp of Boulogne and other points on the English Channel
IV. "	Soult	
V. "	Lannes	
VI. "	Ney	
VII. "	Augereau	Paris
Guard	Bessières	

The corps were, however, by no means fit for immediate service. Bernadotte's corps in Hanover was almost in the position of a

beleaguered garrison, and the marshal could only obtain his transport by giving out that he was ordered to withdraw to France. Marmont and Davout were deficient in horses for cavalry and artillery, and the troops in Boulogne, having been drawn together for the invasion of England, had hardly any transport at all, as it was considered this want could be readily supplied on landing. The composition of the army, however, was excellent. The generals were in the prime of life, had not yet learnt to distrust one another, and were accustomed to work under the emperor and with one another. The regimental officers had all acquired their rank before the enemy and knew how to manage their men, and of the men themselves nearly two-thirds had seen active service. The strength of the army lay in its infantry, for both cavalry and artillery were short of horses, and the latter had not yet acquired mobility and skill in manoeuvring. Napoleon's determination to undertake the invasion of England has often been disputed, but it is hard to imagine what other operation he contemplated, for the outbreak of hostilities with his continental enemies found him ill-supplied with intelligence as to the resources of the country he had then to traverse. To remedy this, Murat and other general officers as well as minor agents were sent ahead and instructed to travel through South Germany in plain clothes with a view to collecting information and mastering the topography. The emperor was, moreover, imperfectly acquainted with the degree of preparation of his adversaries' designs, and when he dictated his preliminary orders he was still unaware of the direction that the allies' advance would assume. On Aug. 26, however, he learnt that 100,000 Russians were about to enter Bohemia thence to unite with an Austrian army of 80,000 near the junction of the Inn and Danube, and this information drove him to alter the general direction of his advance so as to traverse the defiles of the Black Forest north of the Neckar, cavalry only observing the passes to the south.

Austrian Army.—The Austrians after the defeats of 1800 had endeavoured to reorganize their forces on the French model, but they were soon to learn that in matters of organization the spirit is everything, the letter very little. They had copied the organization of the French corps, but could find no corps commanders fit to assume the responsibility for these commands. As always in such conditions, the actual control of the smallest movements was still centralized in the hands of the army commanders, and thus the rate of marching was incredibly slow. They had decided that in future their troops in the field should live by requisition, and had handed over to the artillery, which needed them badly, a large number of horses thus set free from the transport service, but they had not realized that men accustomed to a regular distribution of rations cannot be transformed into successful marauders and pillagers by a stroke of the pen; and they had sent away the bulk of their army, 120,000 under their best general, the archduke Charles, into Italy, leaving Mack von Leiberich in Germany, nominally as chief of the staff to the young Prince Ferdinand, but virtually in command, to meet the onset of Napoleon at the head of his veterans. Mack had the distinction of having risen from the ranks in the most caste-ridden army in Europe.

The March on Ulm.—The outbreak of the campaign was hastened by the desire of the Austrian government to feed their own army and leave a bare country for Napoleon by securing the resources of Bavaria. It was also hoped that the Bavarians with their army of 25,000 men would join the allies. In the latter hope they were deceived, and the Bavarians under General Wrede slipped away to Bamberg in time. In the former, however, they were successful, and the destitution they left in their wake almost wrecked Napoleon's subsequent combinations. Mack's march to Ulm was therefore a necessity of the situation, and his continuance in this exposed position, if foolhardy against such an adversary, was at any rate the outcome of the high resolve that even if beaten he would inflict crippling losses upon the enemy. Mack knew that the Russians would be late at the rendezvous on the Inn. By constructing an entrenched camp at Ulm and concentrating all the available food within it, he expected to compel Napoleon to invest and besiege him, and he

anticipated that in the devastated country his adversary would be compelled to separate and thus fall an easy prey to the Russians. For that blow he had determined to make his own army the anvil. But these views obviously could not be published in army orders, hence the discontent and opposition he was destined to encounter.

Movements of the French.—It was on Sept. 21 that Napoleon learnt of Mack's presence in Ulm. On that date his army had crossed the Rhine and was entering the defiles of the Black Forest. It was already beginning to suffer. Boots were worn out, greatcoats deficient, transport almost unattainable and, according to modern ideas, the army would have been considered incapable of action.

On Sept. 26 its deployment beyond the mountains was complete, and as Napoleon did not know of Mack's intention to stay at Ulm and had learned that the Russian advance had been delayed, he directed his columns by the following roads on the Danube, between Donauwörth and Ingolstadt, so as to be in a position to intervene between the Austrians and the Russians and beat both in detail.

	Sept. 28	Oct. 6	Oct. 9	Oct. 16
Bernadotte	Würzburg	Anspach	Nürnberg	Regensburg
Marmont	Würzburg	Anspach	Nürnberg	Regensburg
Davout	Mannheim	Mergentheim	Anspach	Dietfurt
Ney	Selz	Crailsheim	Weissenburg	Ingolstadt
Lannes	Strassburg	Gmünd	Nördlingen	Neuburg
Soult	Landau	Aalen	Donauwörth	

On Oct. 7 this movement was completed—the Austrians abandoned the Danube bridges after a show of resistance, retreating westward—and Napoleon, leaving Murat in command of the V. and VI. corps and cavalry to observe the Austrians, pressed on to Augsburg with the others so as to be ready to deal with the Russians. Learning, however, that these were still beyond striking radius, he determined to deal with Mack's army first, having formed the fixed conviction that a threat at the latter's communications would compel him to endeavour to retreat southwards towards Tirol. Bernadotte in his turn became an army of observation, and Napoleon joining Murat with the main body marched rapidly westward from the Lech towards the Iller.

Austrian Plans.—Mack's intentions were not what Napoleon supposed. He had meanwhile received (false) information of a British landing at Boulogne, and he was seriously deceived as to the numbers of Napoleon's forces. He was also aware that the exactions of the French had produced deep indignation throughout Germany and especially in Prussia whose neutrality had been violated. All this, and the almost mutinous discontent of his generals and his enemies of the court circle, shook his resolution of acting as anvil for the Russians, of whose delay also he was aware, and about Oct. 8 he determined to march out north-eastward across the French lines of communication and save his sovereign's army by taking refuge if necessary in Saxony. Believing implicitly in the rumours of a descent on Boulogne and of risings in France which also reached him, and knowing the destitution he had left behind him in his movement to Ulm, when he heard of the westward march of French columns from the Lech he told his army, apparently in all good faith, that the French were in full march for their own country.

Actually the French at this moment were suffering the most terrible distress—up to the Danube they had still found sufficient food for existence, but south of it, in the track of the Austrians, they found nothing. All march discipline disappeared, the men dissolved into hordes of marauders and even the sternest of the marshals wrote piteous appeals to the emperor for supplies, and for permission to shoot some of their stragglers. But to all these Berthier in the emperor's name sent the stereotyped reply—"The emperor has ordered you to carry four days' provisions, therefore you can expect nothing further—you know the emperor's method of conducting war."

Action of Albeck or Haslach.—Meanwhile Murat, before the emperor joined him, had given Mack the desired opening. The VI. corps (Ney) should have remained on the left bank of the

Danube to close the Austrian exit on that side, but by mistake only Dupont's division had been left at Albeck, the rest being brought over the river. Mack on the 8th had determined to commence his withdrawal, but fortune now favoured the French. The weather during the whole of October had been unusually wet, the swollen Danube overflowed the low ground and the roads had become quagmires. On the south bank, owing to better natural drainage and a drier subsoil, movement was fairly easy, but the Austrians found it almost impossible. On Oct. 11, when they began their march, the road along the Danube was swept into the river, carrying with it several guns and teams, and hours were consumed in passing the shortest distances. At length in the afternoon they suddenly fell upon Dupont's isolated division at Albeck, which was completely surprised and severely handled. The road now lay completely open, but the Austrian columns had so opened out owing to the state of the roads that the leading troops could not pursue their advantage—Dupont rallied and the Austrians had actually to fall back towards Ulm to procure food.

Elchingen.—For three more days Mack struggled with an unwilling staff and despondent men to arrange a further advance. During these very three days, through a succession of staff blunders, the French failed to close the gap, and on the morning of Oct. 14 the armies, each renewing its advance, came in contact at the bridge of Elchingen. This bridge, all but a few road-bearers, had been destroyed, but now the French gave an example of that individual gallantry which was characteristic of the old revolutionary armies. Running along the beams under a close fire a few gallant men forced their way across. The floor of the bridge was rapidly relaid, and presently the whole of the VI. corps was deploying with unexampled rapidity on the farther side. The Austrians, still in their quagmire, could not push up reinforcements fast enough, and though Mack subsequently alleged deliberate obstruction and disobedience on the part of his subordinates, the state of the roads alone suffices to explain their defeat. Only the right column of the Austrians was, however, involved; the left under General Werneck, to whom some cavalry and the archduke Ferdinand attached themselves, did indeed succeed in getting away, but without trains or supplies. They continued their march, famished but unmolested, until near Heidenheim they suddenly found themselves confronted by what from the diversity of uniforms they took to be an overwhelming force; at the same time the French cavalry sent in pursuit appeared in their rear. Utterly exhausted by fatigue, Werneck with his infantry, some 8,000 strong, surrendered to what was really a force of dismounted dragoons and foot-sore stragglers improvised by the commanding officer on the spot to protect the French treasure chests, which at that moment lay actually in the path of the Austrians. The young archduke with some cavalry escaped.

Mack Surrounded.—The defeat at Elchingen on Oct. 14 sealed the fate of the Austrians, though Mack was still determined to endure a siege. As the French columns coming up from the south and west gradually surrounded him, he drew in his troops under shelter of the fortress and its improvised entrenched camp, and on the 15th he found himself completely surrounded. On the 16th the French field-guns fired into the town, and Mack realized that his troops were no longer under sufficient control to endure a siege. When, therefore, next morning, negotiations were opened by the French, Mack, still feeling certain that the Russians were at hand, agreed to an armistice and undertook to lay down his arms if within the next twenty-one days no relief should arrive. To this Napoleon consented, but hardly had the agreement been signed when he succeeded in introducing a number of individual French soldiers into the fortress, who began rioting with the Austrian soldiery. Then, sending in armed parties to restore order and protect the inhabitants, he caused the guards at the gates to be overpowered, and Mack was thus forced into an unconditional surrender.

On Oct. 22, the day after Trafalgar, the remnant of the Austrian army, 23,000 strong, laid down its arms. About 5,000 men under Jellachich had escaped to Tirol, 2,000 cuirassiers with Prince Ferdinand to Eger in Bohemia, and about 10,000 men

under Werneck had surrendered at Heidenheim. The losses in battle having been insignificant, there remain some 30,000 to account for—most of whom probably escaped individually by the help of the inhabitants, who were bitterly hostile to the French. Napoleon now hastened to rejoin the group of corps he had left under Bernadotte in observation towards the Russians, for the latter were nearer at hand than even Mack had assumed. But hearing of his misfortune they retreated before Napoleon's advance along the right bank of the Danube to Krems, where they crossed the river and withdrew to an entrenched camp near Olmütz to pick up fresh Austrian reinforcements. The severe actions of Dürrenstein (near Krems) on Nov. 11, and of Hollabrunn on Nov. 16, in which Napoleon's marshals learned the tenacity of their new opponents, and the surprise of the Vienna bridge (November 14) by the French, were the chief incidents of this period in the campaign.

Campaign of Austerlitz.—Napoleon continued down the right bank to Vienna, where he was compelled by the condition of his troops to call a halt to refit his army. After this was done he continued his movement to Brünn. Thither he succeeded in bringing only 55,000 men. He was again forced to give his army rest and shelter, under cover of Murat's cavalry. The allies now confronted him with upwards of 86,000 men, including 16,000 cavalry. About Nov. 20 this force commenced its advance, and Napoleon concentrated in such a manner that within three days he could bring over 80,000 French troops into action around Brünn, besides 17,000 or more Bavarians under Wrede. On the 28th Murat was driven in by the allied columns. That night orders were despatched for a concentration on Brünn in expectation of a collision on the following day; but hearing that the whole allied force was moving towards him he decided to concentrate south-east of Brünn, covering his front by cavalry on the Pratzen heights. Meanwhile he had also prepared a fresh line of retreat towards Bohemia, and, certain now of having his men in hand for the coming battle, he quietly awaited events.

The allies were aware of his position, and still adhering to the old "linear" system, marched to turn his right flank (see AUSTERLITZ). As soon as their strategic purpose of cutting him off from Vienna became apparent, the emperor moved his troops into position, and in the afternoon issued his famous proclamation to his troops, pointing out the enemy's mistakes and his plan for defeating them. At the same time he issued his orders for his first great battle as a supreme commander. The battle of Austerlitz began early next morning and closed in the evening with the thorough and decisive defeat of the allies.

PRUSSIAN AND POLISH CAMPAIGNS

Around the Prussian army, and particularly the cavalry, the prestige of Frederick the Great's glory still lingered; but the younger generation had little experience of actual warfare, and the higher commanders were quite unable to grasp the changes in tactics and in the conduct of operations which had grown out of the necessities of the French Revolution. The individual officers of the executive staff were the most highly trained in Europe, but there was no great leader to co-ordinate their energies. The total number of men assigned to the field army was 110,000 Prussians and Saxons. They were organized in corps, but their leaders were corps commanders only in name, for none were allowed any latitude for individual initiative. Ill-judged economies had undermined the whole efficiency of the Prussian army. Two-thirds of the infantry and one-half of the cavalry were allowed furlough for from ten to eleven months in the year. The men were unprovided with greatcoats. Most of the muskets had actually seen service in the Seven Years' War, and their barrels had worn so thin with constant polishing that the use of full charges at target practice had been forbidden. Above all, the army had drifted entirely out of touch with the civil population. The latter, ground down by feudal tradition and law, and at the same time permeated by the political doctrines of the late 18th century, believed that war concerned the governments only, and formed no part of the business of the "honest citizen." In this idea they were supported by the law itself, which protected the civilian against the soldier, and forbade even in war-time the requisition-

ing of horses, provisions and transport, without payment. Up to the night of the battle of Jena itself, the Prussian troops lay starving in the midst of plenty, whilst the French everywhere took what they wanted. This alone was a sufficient cause for all the misfortunes which followed.

During the campaign of Austerlitz Prussia, furious at the violation of her territory of Anspach, had mobilized, and had sent Haugwitz as ambassador to Napoleon's headquarters. He arrived on Nov. 30, and Napoleon, pleading business, put off his official reception till after the battle of Austerlitz. Of course the ultimatum was never presented, as may be imagined; Haugwitz returned and the king of Prussia demobilized at once. But Napoleon, well knowing the man he had to deal with, had determined to force a quarrel upon Prussia at the earliest convenient opportunity. His troops therefore, when withdrawn from Austria, were cantoned in south Germany in such a way that, whilst suspicion was not aroused in minds unacquainted with Napoleonic methods, they could be concentrated by a few marches behind the Thuringian forest and the upper waters of the Main. Here the Grande Armée was left to itself to recuperate and assimilate its recruits, and it is characteristic of the man and his methods that he did not trouble his corps commanders with a single order during the whole of the spring and summer.

As the diplomatic crisis approached, spies were sent into Prussia, and simultaneously with the orders for preliminary concentration the marshals received private instructions, the pith of which cannot be better expressed than in the following two quotations from Napoleon's correspondence:—

"Mon intention est de concentrer toutes mes forces sur l'extrémité de ma droite en laissant tout l'espace entre le Rhin et Bamberg entièrement dégarni, de manière à avoir près de 200,000 hommes réunis sur un même champ de bataille; mes premières marches menacent le cœur de la monarchie prussienne" (No. 10,920). "Avec cette immense supériorité de forces réunis sur un espace si étroit, vous sentez que je suis dans la volonté de ne rien hasarder et d'attaquer l'ennemi partout où il voudra tenir. Vous pensez bien que ce serait une belle affaire que de se porter sur cette place (Dresden) en un bataillon carré de 200,000 hommes" (Soult, No. 10,941).

Advance of the Grande Armée.—On Oct. 7 the Grande Armée lay in three parallel columns along the roads leading over the mountains to Hof, Schleiz and Kronach; on the right lay the IV. corps (Soult) about Bayreuth, with his cavalry in rear, and behind these the VI. corps (Ney) at Pegnitz; in the centre, Bernadotte's I. corps from Nordhalben, with the III. corps (Davout) Lichtenfels; Guard and headquarters, Bamberg. The left column was composed of the V. (Lannes) at Hemmendorf, with the VII. (Augereau) extending south to the Main at Burgebrach.

Napoleon's object being surprise, all the cavalry except a few vedettes were kept back behind the leading infantry columns and these latter were ordered to advance, on the signal being given, in "masses of manoeuvre," so as to crush at once any outpost resistance which was calculated upon the time required for the deployment of ordinary marching columns. This order has never since found an imitator, but deserves attentive study as a masterpiece (see H. Bonnal, *Manoeuvre d'Iéna*).

To meet the impending blow the Prussians had been extended in a cordon along the great road leading from Mainz to Dresden, Blücher was at Erfurt, Rüchel at Gotha, Hohenlohe at Weimar, Saxons in Dresden, with outposts along the frontier. An offensive move into Franconia was under discussion, and for this purpose the Prussian staff had commenced a lateral concentration about Weimar, Jena and Naumburg when the storm burst upon them. The emperor gathered little from the confused reports of their purposeless manoeuvres, but, secure in the midst of his "battalion square" of 200,000 men, he remained quite indifferent, well knowing that an advance straight on Berlin must force his enemy to concentrate and fight, and as they would bring at most 127,000 men on to the battlefield the result could hardly be doubtful. On Oct. 9 the cloud burst. Out of the forests which clothe the northern slopes of the Thuringer Wald the French streamed forth, easily overpowering the resistance of the Prussian outposts on the upper Saale, and once the open country was reached the cavalry under Murat trotted to the front, closely followed by

Bernadotte's corps as "general advance guard." The result of the cavalry scouting was, however, unsatisfactory. On the night of the 10th, the emperor was still unaware of the position of his principal foe, and Murat with Bernadotte behind him was directed on Gera for the 11th, the remainder of the army continuing along the roads previously assigned to them.

In the meanwhile, however, the Saxons had been moving from Naumburg through Gera on Jena, Hohenlohe was near Weimar, and all the other divisions of the Prussian army had closed in a march eastwards, the idea of an offensive to the southward which Napoleon had himself attributed to them having already disappeared.

Reaching Gera at 9 A.M. Murat reported the movement of the Saxons on the previous day, but omitted to send a strong detachment in pursuit. The traces of the Saxons were lost, and Napoleon, little satisfied with his cavalry, authorized Lasalle to offer up to 6,000 frs. reward for information of the Prussian point of concentration. At 1 A.M. of the 12th Napoleon issued his orders: Murat and Bernadotte via Zeitz to Naumburg; Davout (III. corps and a dragoon division) also to Naumburg; Lannes to Jena, Augereau following; Soult to Gera.

In the meantime the Prussians were effecting their concentration. Rüchel, who with 15,000 men had been sent into the mountains as an advance guard for the projected offensive, was recalled to Weimar, which he reached on the 13th. The main body were between Weimar and Apolda during the 12th, and the Saxons duly effected their junction with Hohenlohe in the vicinity of Vierzeheiligen, whilst the latter had withdrawn his troops, all but some outposts from Jena, to the plateau about Capellendorf, some 4m. to the N.W. The whole army, of over 120,000 men, could therefore have been concentrated against Lannes and Augereau by the afternoon of the 13th, whilst Soult could

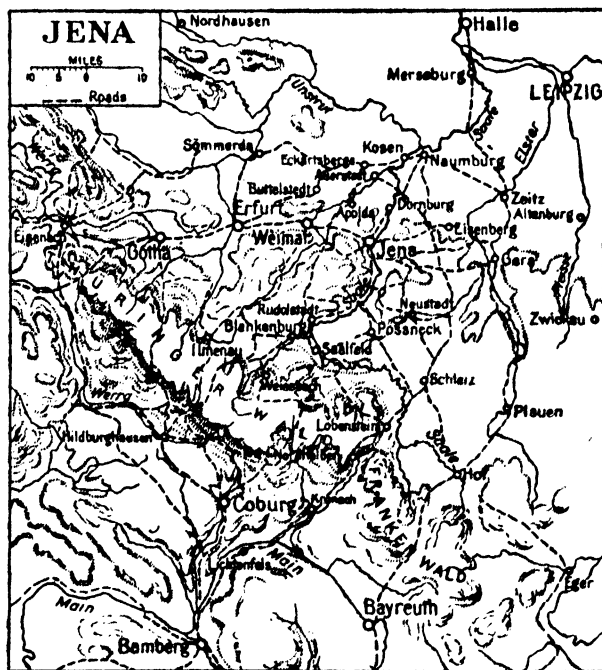

FIG. 2.—JENA CAMPAIGN

only have intervened very late in the day, and Davout and Bernadotte were still too distant to reach the battlefield before the 14th. All the French corps, moreover, were so exhausted by their rapid marches over bad roads that the emperor actually ordered (at 1 A.M. on the 13th) a day of rest for all except Davout, Bernadotte, Lannes and Murat.

The Prussian headquarters, however, spent the 12th and 13th in idle discussion, whilst the troop commanders exerted themselves to obtain some alleviation for the suffering of their starving men. The defeats undergone by their outpost detachment had

profoundly affected the nerves of the troops, and on the afternoon of the 11th, on the false alarm of a French approach, a panic broke out in the streets of Jena, and it took all the energy of Hohenlohe and his staff to restore order. On the morning of the 12th the Saxon commanding officers approached Hohenlohe with a statement of the famishing condition of their men, and threatened to withdraw them again to Saxony. Hohenlohe pointed out that the Prussians were equally badly off, but promised to do his best to help his allies. Urgent messages were sent off to the Commissary von Goethe (the poet), at Weimar for permission to requisition food and firewood. These requests, however, remained unanswered, and the Prussians and Saxons spent the night before the battle shivering in their miserable bivouacs.

The 13th of October.—During the early morning of the 13th the reports brought to Napoleon at Gera partially cleared up the situation, though the real truth was very different from what he supposed. However, it was evident that the bulk of the Prussians lay to his left, and instructions were at once despatched to Davout to turn westward from Naumburg towards Kösen and to bring Bernadotte with him if the two were still together. The letter, however, ended with the words "but I hope he is already on his way to Dornburg." Now Bernadotte had neglected to keep the emperor informed as to his whereabouts. He was still with Davout, but, concluding that he had missed an order directing him to Dornburg, he thought to conceal his error by assuming the receipt of the order evidently alluded to in the last words, and as a result he marched towards Dornburg, and his whole corps was lost to the emperor at the crisis of the next day's battle.

On the road from Gera to Jena Napoleon was met by intelligence from Lannes announcing his occupation of Jena and the discovery of Prussian troops to the northward. Knowing the emperor's methods, he wisely restrained the ardour of his subordinates and asked for instructions whether to attack or wait. The emperor rode forward rapidly, reached Jena about 3 P.M., and with Lannes proceeded to the Landgrafenberg to reconnoitre. From this point his view was, however, restricted to the immediate foreground, and he only saw the camps of Hohenlohe's left wing. At this moment the Prussians were actually on parade and ready to move off to attack, but just then the "evil genius" of the Prussian army, Massenbach, an officer of the Headquarters Staff, rode up and claiming to speak with the authority of the king and commander-in-chief, induced Hohenlohe to order his troops back to camp. Of all this Napoleon saw nothing, but from all reports he came to the conclusion that the whole Prussian army was actually in front of him, and at once issued orders for his whole army to concentrate towards Jena, marching all night if need be. Six hours earlier his conclusion would have been correct, but early that morning the Prussian headquarters, alarmed for the safety of their line of retreat on Berlin by the presence of the French in Naumburg, decided to leave Hohenlohe and Rüdchel to act as rear-guard, and with the main body to commence their retreat towards the river Unstrutt and the Eckhardtsberge where Massenbach had previously reconnoitred an "ideal" battlefield. This belief in positions was the cardinal principle of Prussian strategy in those days. The troops had accordingly commenced their march on the morning of the 13th, and now at 3 P.M. were settling down into bivouac; they were still but a short march from the decisive field.

Battle of Jena.—On the French side, Lannes' men were working their hardest, under Napoleon's personal supervision, to make a practicable road up to the Landgrafenberg, and all night long the remaining corps struggled through darkness towards the rendezvous. By daybreak on the 14th, the anniversary of Elchingen, upwards of 60,000 men stood densely packed on the narrow plateau of the mountain, whilst, below in the ravines on either flank, Soult on the right, and Augereau on the left, were getting into position. Fortunately a dense fog hid the helpless masses on the Landgrafenberg from sight of the Prussian gunners. Hohenlohe had determined to drive the French into the ravine at daybreak, but had no idea as to the numbers in front of him. For want of room, only a few Prussian battalions were sent forward, and these, delaying their advance till the fog had

sufficiently lifted, were met by French skirmishers, and small columns, who rapidly overlapped their flanks and drove them back in confusion. Hohenlohe now brought up the remainder of his command, but in the meanwhile the French had poured across the neck between the Landgrafenberg and the main plateau, and the troops of Soult and Augereau were working up the ravines on either hand. In view of these troops the Prussian line, which had advanced faultlessly as if on parade, halted to prepare its bayonet attack by fire, and, once halted, it was found impossible to get them to go on again. The French, who had thrown themselves into houses, copses, etc., picked off the officers, and the flanks of the long Prussian lines swayed and got into confusion. The rival artilleries held each other too thoroughly to be able to spare attention to the infantry, whilst the Prussian cavalry, which had forgotten how to charge in masses of eighty or more squadrons, frittered away their strength in isolated efforts. By 10 A.M. the fourteen battalions which had initiated this attack were outnumbered by three to one, and drifted away from the battlefield. Their places were taken by a fresh body, but this was soon outnumbered and outflanked in its turn. By 2 P.M. the psychological moment had come, and Napoleon launched his guards and cavalry to complete the victory and initiate pursuit. Rüdchel's division now arrived and made a most gallant effort to cover the retreat, but their order being broken by the torrent of fugitives, they were soon overwhelmed by the tide of the French victory and all organized resistance had ceased by 4 P.M.

Briefly summarized, the battle came to this—in four successive efforts the Prussians failed because they were locally outnumbered. This was the fault of their leaders solely, for, except for the last attack, local superiority was in each case attainable. Organization and tactics did not affect the issue directly, for the conduct of the men and their junior officers gave abundant proof that in the hands of a competent leader the "linear" principle of delivering one shattering blow would have proved superior to that of a gradual attrition of the enemy here, as on the battlefields of the Peninsula and at Waterloo, and this in spite of other defects in the training of the Prussian infantry which simultaneously caused its defeat on the neighbouring field of Auerstädt.

Battle of Auerstädt.—Here the superiority of French mobility showed its value most conclusively. Davout in obedience to his orders of the previous morning was marching over the Saale at Kösen, when his advanced guard and that of the Prussian main army came unexpectedly in contact. The latter with at least 50,000 men was marching in two columns, and ought therefore to have delivered its men into line of battle twice as fast as the French, who had to deploy from a single issue, and whose columns had opened out in the passage of the Kösen defile and the long ascent of the plateau above. But the Prussians attacked at the old regulation speed of seventy-five paces to the minute, and the French manoeuvred at the quick or double of 120 or 150. The consequence was that the French always succeeded in reinforcing their fighting line in time to avert disaster. Nevertheless by mid-day their strength was well-nigh exhausted, whilst the Prussian reserve, eighteen battalions of guards under Kalkreuth, stood intact and ready to engage. But at the critical moment the duke of Brunswick fell mortally wounded, and Scharnhorst, his chief of the staff, was at the time absent on another part of the field. Meanwhile rumours from the battlefield at Jena, magnified as usual, began to reach the staff, and these may possibly have influenced Kalkreuth, for when called upon to attack with his eighteen battalions and win the day, he declined to move without the direct order of the commander-in-chief to do so, alleging that it was the duty of a reserve to cover the retreat and he considered himself personally responsible to the king for the guards entrusted to his care. Even then the day might possibly have been saved had Blücher been able to find even twenty squadrons accustomed to gallop together, but the Prussian cavalry had been dispersed amongst the infantry commands, and at the critical moment it proved impossible for them to deliver a united and decisive attack.

Seeing further efforts hopeless, Scharnhorst in the duke's name initiated the retreat and the troops withdrew north-west towards Buttelstedt, almost unmolested by the French, who this day had

gear, or for the cavalry to replace their jaded horses from captured Prussian resources, he set Davout in motion towards Warsaw on Nov. 2, and the remainder of the army followed in successive echelons as rapidly as they could be despatched.

The cavalry, moving well in advance, dispersed the Prussian depots and captured their horses, as far as the line of the Vistula, where at last they encountered organized resistance from the

FIG. 5.—CAMPAIGN OF 1807

outposts of Lestocq's little corps of 15,000 men—all that was left of Frederick the Great's army. These, however, gave way before the threat of the advancing French and, after a few trifling skirmishes, Davout entered Warsaw on Nov. 30, being followed by the V., IV., and Guard corps during the succeeding fortnight, whilst the VI. and VII. were echeloned to their left, and the VIII. (Mortier) and IX. (Jerome Napoleon) and X. (Lefebvre), all new formations since the outbreak of the war, followed some marches in the rear. Jerome's corps was composed of the Bavarians, Württembergers and Badensers.

Behind these all Prussia was overrun by newly formed units, (3rd and 4th battalions) raised from depot companies, conscripts for 1807, and old soldiers rejoining after sickness or wounds. Napoleon caused these to be despatched to the front immediately after their formation. He had much territory to occupy, and on the long march of on an average 85 days, he considered that they could be organized, equipped and drilled *en route*.

Pultusk.—The Russians meanwhile had been moving slowly forward in two bodies, one under Bennigsen (50,000), the other under Buxhowden (25,000), and the French being at this time in Warsaw, they took up threatening positions about Pultusk, Plock and Prassnitz. From this triangle they harried the French communications with Berlin, and to secure a winter's rest for his men Napoleon determined to bring them to action. On Dec. 23 operations were commenced, but the difficulties of securing information and maintaining communication between the respective columns, so unlike what any of the French had previously encountered, led to a very partial success. The idea had been to induce the Russians to concentrate about Pultusk and, turning their position from its left, ultimately to cut them off from Russia, and if possible to surround them. But in this new and difficult country the emperor found it impossible to time his marches. The troops arrived late at their appointed positions, and after a stubborn rearguard action at Pultusk itself and undecided fighting elsewhere (Golymin and Soldau) the Russians succeeded in retreating beyond the jaws of the French attack, and Napoleon for the first time found that he had exceeded the limit of endurance of his men. Indeed, the rank and file bluntly told him as much as he rode with the marching columns. Yielding to

the inevitable, but not forgetting to announce a brilliant victory in a bulletin, he sent his troops into winter quarters along the Passarge and down the Baltic, enjoining on his corps commanders most strictly to do nothing to disturb their adversary.

Campaign of Eylau.—Bennigsen, now commanding the whole Russian army which with Lestocq's Prussians amounted to 100,000, also moved into winter quarters in the area Deutsch Eylau-Osterode-Allenstein, and had every intention of remaining there, for a fresh army was already gathering in Russia, the first corps of which had reached Nur about 50m. distant from the French right.

Unfortunately, Ney with his VI. corps about Gilgenberg had received the most poverty-stricken district in the whole region, and to secure some alleviation for the sufferings of his men he incautiously extended his cantonments till they came in contact with the Russian outposts. Apparently seeing in this movement a recommencement of hostilities, Bennigsen concentrated his troops towards his right and commenced an advance westwards towards Danzig, which was still in Prussian hands. Before his advance both Ney and Bernadotte (the latter, between Ney and the Baltic, covering the siege of Danzig) were compelled to fall back. It then became necessary to disturb the repose of the whole army to counter the enemy's intentions. The latter by this movement, however, uncovered his own communication with Russia, and the emperor was quick to seize his opportunity. He received the information on Jan. 28. His orders were at once issued and complied with so rapidly that by the 31st he stood prepared to advance with the corps of Soult, Ney, Davout and Augereau, the Guard and the reserve cavalry (80,000 men on a front of 60m.) from Myszienec through Willenberg to Gilgenberg; whilst Lannes on his right towards Ostrolenka and Lefebvre (X.) at Thorn covered his outer flanks.

Bernadotte, however, was missing, and this time through no fault of his own. His orders and the despatch conveying Napoleon's instructions fell into the hands of the Cossacks, and just in time Bennigsen's eyes were opened. Rapidly renouncing his previous intentions, he issued orders to concentrate on Allenstein; but this point was chosen too far in advance and he was anticipated by Murat and Soult at that place on Feb. 2. He then determined to unite his forces at Joukendorf, but again he was too late. Soult and Murat attacked his rearguard on the 3rd, and Bennigsen, learning from his Cossacks that the French corps were designing to swing round and enclose him, he withdrew by a night march and ultimately succeeded in getting his whole army, with the exception of Lestocq's Prussians, together in the strong position along the Alle, the centre of which is marked by Preussisch-Eylau. The opportunity for this concentration Bennigsen owed to the time gained for him by his rearguard at Joukendorf, for this had stood just long enough to induce the French columns to swing in to surround it, and the next day was thus lost to the emperor as his corps had to extend again to their manoeuvring intervals. The truth is that the days were too short and the roads too bad for Napoleon to carry out the full purpose his "general advance guard" was intended to fulfil. It was designed to hold the enemy in position by the vigour of its attack, thus neutralizing his independent will power and compelling him to expend his reserves in the effort to rescue the troops engaged. But in forests and snowdrifts the French made such slow progress that no sufficient deployment could be made until darkness put a stop to the fighting. Thus, when late on Feb. 7, 1807 Murat and Soult found the enemy's rearguard near Eylau (*q.v.*) the fighting was severe but not prolonged. This time, however, Bennigsen, with over 60,000 men in position and 15,000 Prussians expected to arrive next morning, had no desire to avoid a battle, and deployed for action.

During the night Augereau and the Guards had arrived, and Ney and Davout were expected on either flank in the forenoon. This time the emperor was determined that his enemy should not escape him, and about 8 A.M. ordered Soult and Augereau on the left and right respectively to assail the enemy, Murat and the Guards remaining in the centre as reserve. Napoleon's own forces thus became the "general advance guard" for Ney and

Davout, who were to close in on either side and deliver the decisive stroke. But here too the weather and the state of the roads operated adversely, for Ney came up too late, while Davout, in the full tide of his victorious advance, was checked by the arrival of Lestocq, whose corps Ney had failed to intercept, and the attack of Augereau's corps (VII.), made in a blinding snowstorm, failed with appalling loss. Bennigsen, however, drew off on Ney's arrival, and the French were too much exhausted to pursue him. Again the emperor had to admit that his troops could do no more, and bowing to necessity, he distributed them into winter quarters, where, however, the enterprise of the Cosacks, who were no strangers to snow and to forests, left the outposts but little repose. A protracted period of rest followed, during which the emperor exerted himself unremittingly to re-equip, reinforce and supply his troops. Hitherto he had been based on the entrenched camp of Warsaw, but he had already taken steps to organize a new line of supply and retreat via Thorn, and this was now completed. At the same time Lefebvre was ordered to press the siege of Danzig with all vigour, and on May 5, after a most gallant resistance, Kalckreuth, who redeemed here his failure of Auerstädt, surrendered. English assistance came too late. By the beginning of June the French had more than made good their losses and 210,000 men were available for field service.

Heilsberg and Friedland.—Meanwhile Bennigsen had prepared for a fresh undertaking, and leaving Lestocq with 20,000 Prussians and Russians to contain Bernadotte, who lay between Braunsberg and Spandau on the Passarge, he moved southwards on the 2nd, and on June 3 and 4 he fell upon Ney, driving him back towards Guttstadt, whilst with the bulk of his force he moved towards Heilsberg, where he threw up an entrenched position. It was not till the 5th that Napoleon received tidings of his advance, and for the moment these were so vague that he contented himself by warning the remainder of his forces to be prepared to move on the 6th. Next day, however, all doubts were set at rest, and as the Russians advanced south of Heilsberg, he decided to wheel his whole force to the right, pivoting on the III. corps, and cut Bennigsen off from Königsberg and the sea. On the 8th the VI., III., VIII. and Guard corps, together with a new cavalry reserve corps under Lannes, in all 147,000, stood ready for the operation, and with Murat and Soult as general advanced guard the whole moved forward, driving the Russian outposts before them. Bernadotte, who was to have attacked Lestocq, again failed to receive his orders and took no part in the following operations.

Murat attacked the Russians, who had halted in their entrenched position, on the 11th and drove in their outposts, but did not discover the entrenchments. Meanwhile Soult had followed with his infantry in close support, and the emperor himself arriving, ordered him to attack at once. Now the Russians uncovered their entrenchments, and in the absence of artillery preparation Soult's leading troops received most severe punishment. Fresh troops arriving were sent in to his support, but these also proved insufficient, and darkness alone put an end to the struggle, which cost the French 12,000 killed and wounded.

Bennigsen, however, learning that his right was threatened by the III. corps, and not having as yet completed his concentration, retreated in the night to Bartenstein, and the following day turned sharp right towards Schippenbeil. The emperor now pressed on towards Friedland, where he would completely control the Russian communications with Königsberg, their immediate base of supply, but for once the Russians outmarched him and covered their movement so successfully that for the next three days he seems to have completely lost all knowledge of his enemy's whereabouts. Lestocq in the meantime had been forced northwards towards Königsberg, and Soult with Murat was in hot pursuit. The III., VI., VIII. and Guard corps followed the main road towards Königsberg, and the former had reached Mühlhausen, the remainder were about Preussisch-Eylau, when Latour Maubourg's dragoons sent in intelligence which pointed to the presence of Bennigsen about Friedland. This was indeed the case. The Russians after passing Schippenbeil had suddenly turned

northwards, and on the evening of the 13th were taking up a strong position on the river Alle with Friedland as a centre.

What followed presents perhaps the finest instance of the Napoleonic method. The enemy lay direct to his right, and Murat, the IV. and III. corps had well overshot the mark. Lannes's reserve corps (cavalry), to whom Latour Maubourg reported, lay at Domnau some 10m. to the right. The latter at once assumed the rôle of advanced guard cavalry and was ordered to observe the enemy at Friedland, Ney following in close support. Davout was turned about and directed on the enemy's right, and the VIII. corps (Mortier), the Guards and the reserve cavalry followed as main body. On the 14th (the anniversary of Marengo) Lannes carried out his rôle of fighting advanced guard or screen, the emperor's main body gradually came up, and the battle of Friedland (*q.v.*), notable chiefly for the first display of the new artillery tactics of the French, ended with a general attack about 5 p.m. and the retreat of the Russians, after severe losses, over the Alle. Lestocq was, meanwhile, driven through Königsberg (which surrendered on the 15th) on Tilsit, and now that he was no longer supported by the Russians, the Prussian commander gave up the struggle.

THE AUSTRIAN WAR OF 1809

Ever since Austerlitz the Austrian officers had been labouring to reconstitute and reform their army. Much had been done to create an efficient staff, but though the idea of the army corps command was now no new thing, the senior generals entrusted with these commands were far from having acquired the independence and initiative of their French opponents. Hence the extraordinary slowness of their manoeuvres, not because the Austrian infantry were bad marchers, but because the preparation and circulation of orders was still far behind the French standard. The infantry adopted the highly manoeuvrable formations of the French—skirmishers and columns—but it was easier to adopt the formations than to acquire the initiative which gave these their vital energy. The light cavalry had been much improved and the heavy cavalry on the whole proved a fair match for their opponents.

After the peace of Tilsit the Grande Armée was gradually withdrawn behind the Rhine, leaving only three commands, totalling 63,000 men, under Davout in Prussia, Oudinot in west central Germany, and Lefebvre in Bavaria, to assist the princes of the Confederation of the Rhine in the maintenance of order and the enforcement of the French law of conscription, which was rigorously insisted on in all the States comprised in this new federation. In exchange for the subsistence of the French troops of occupation, a corresponding number of these new levies were moved to the south of France, where they commenced to arrive at the moment when the situation in Spain became acute. The Peninsular War (*q.v.*) called for large forces of the old *Grande Armée* and for a brief period Napoleon directed operations in person; and the Austrians took advantage of the dissemination and weakness of the French forces in Germany to push forward their own preparations with renewed energy.

But they reckoned without the resourcefulness of Napoleon. The moment news of their activity reached him, whilst still in pursuit of Sir John Moore, he despatched letters to all the members of the Confederation warning them that their contingents might soon be required, and at the same time issued a series of decrees to General Clarke, his war minister, authorizing him to call up the contingent of 1810 in advance, and directing him in detail to proceed with the formation of 4th and 5th battalions for all the regiments across the Rhine. By these means Davout's, Oudinot's and Lefebvre's commands were augmented, whilst in February and March new corps were formed and rapidly pushed towards the front.

On his return from Spain, seeing war imminent, he issued a series of march orders (which deserve the closest study in detail) by which on April 15 his whole army was to be concentrated for manoeuvres between Regensburg, Landshut, Augsburg and Donauwörth, and sending on the Guard in wagons to Strassburg, he despatched Berthier to act as commander-in-chief until his

own arrival.

Austrian Offensive.—The position of assembly was excellently chosen, but unfortunately the Austrians took the initiative. On April 9 their main body of six corps crossed the Inn between Braunau and Passau and simultaneously two additional corps moved from Pilsen in Bohemia on Regensburg. At this moment Davout was entering Regensburg with his leading troops, the remainder still some marches in rear, and it was evident that the whole concentration could no longer be carried out before the Austrians would be in a position to intervene. Berthier received the news while still on his way to the front, and quite failed to grasp the situation. Reaching Donauwörth at 8 P.M. on April 13, he ordered Davout and Oudinot to remain at Regensburg, whilst Lefebvre and Wrede (Bavarians) who had fallen back before the Austrians were directed to reoccupy Landshut. This was in direct contradiction to the instructions Napoleon had given on March 28 in view of this very emergency. Davout obeyed, but remonstrated. On the 16th Berthier went on to Augsburg, where he learned that Lefebvre's advanced troops had been driven out of Landshut, thus opening a great gap seventy-six miles wide between the two wings of the French army. Meanwhile Napoleon, who had left Paris at 4 A.M. on April 13, was hastening towards the front, but remained still in ignorance of Berthier's doings until on the 16th at Stuttgart he received a letter from the Marshal dated the 13th, which threw him into consternation. In reply he immediately wrote: "You do not inform me what has rendered necessary such an extraordinary measure which weakens and divides my troops"—and—"I cannot quite grasp the meaning of your letter yet, I should have preferred to see my army concentrated between Ingolstadt and Augsburg, the Bavarians in the first line, with the duke of Danzig in his old position, until we know what the enemy is going to do. Everything would be excellent if the duke of Auerstädt had been at Ingolstadt and the duke of Rivoli with the Württembergers and Oudinot's corps at Augsburg, . . . so that just the opposite of what should have been done has been done" (C. N. to Berthier, Ludwigsburg, 16th April).

Napoleon Takes Command.—Having despatched this severe reprimand he hastened on to Donauwörth, where he arrived at 4 A.M. on the 17th, hoping to find Berthier, but the latter was at Augsburg. Nevertheless, at 10 A.M. he ordered Davout and Oudinot to withdraw at once to Ingolstadt; and Lefebvre and Wrede on the right to support the movement. About noon Berthier returned and after hearing his explanation Masséna received orders to move from Augsburg toward Ingolstadt. "To-morrow will be a day of preparation spent in drawing closer together, and I expect to be able by Wednesday to manoeuvre against the enemy's columns according to circumstances."

Meanwhile the Austrians had approached so near that by a single day's march it would have been possible to fall upon and crush by superior numbers either wing of the French army, but though the Austrian light cavalry successfully covered the operations of the following troops they had not yet risen to a conception of their reconnoitring mission, and the archduke, in ignorance of his opportunity and possessed, moreover, with the preconceived idea of uniting at Regensburg with the two corps coming from Bohemia, moved the bulk of his forces in that direction, leaving only a covering body against Davout altogether insufficient to retain him. Davout, however, had left a garrison of 1,800 men in Regensburg, who delayed the junction of the Austrian wings until the 20th inst., and on the same day the emperor, having now reunited his whole right wing and centre, overwhelmed the covering detachments facing him in a long series of disconnected engagements lasting forty-eight hours, and the archduke now found himself in danger of being forced back into the Danube. But with the Bohemian reinforcements he had still four corps in hand, and Napoleon, whose intelligence service in the difficult and intersected country had lamentably failed him, had weakened his army by detaching a portion of his force in pursuit of the beaten right wing, and against the archduke's communications.

Eckmühl.—When, therefore, the latter, on the 22nd, marched southward to reopen his communications by the defeat of the

enemy's army, he actually reached the neighbourhood of Eckmühl with a sufficient numerical superiority had he only been prompt enough to seize his opportunity. But the French had been beforehand with him. Napoleon, who had personally taken part in the fighting of the previous day, and followed the pursuit as far as Landshut, whence he had despatched Masséna to follow the retreating Austrians along the Isar, seems to have realized about

FIG. 6.—ECKMÜHL, 1809

3 A.M. in the morning that it was not the main body of the enemy he had had before him, but only its left wing, and that the main body itself must still be northward towards Regensburg. Issuing orders to Davout, Oudinot and his cavalry to concentrate with all speed towards Eckmühl, he himself rode back along the Regensburg road and reached the battle-field just as the engagement between the advance troops had commenced. Had the Austrians possessed mobility equal to that of the French the latter should have been overwhelmed in detail, but whilst the French covered 17 and 19m. the Austrians only marched 10, and, owing to their defective assimilation of the new tactical training the troops actually on the ground could not hold out long enough for their reserves to arrive. The retreat of the front lines involved the following ones in confusion, and presently the whole mass was driven back in considerable disorder. It seemed as if nothing could save the Austrians from complete disaster, but at the critical moment the emperor, yielding to the protestations of his corps commanders, who represented the excessive fatigue of their troops, stopped the pursuit, and the archduke made the most of his opportunity to restore order amongst his demoralized men and crossed to the north bank of the Danube during the night.

On the following morning the French reached Regensburg and at once proceeded to assault its mediaeval walls, but the Austrian garrison bravely defended it till the last of the stragglers was safely across on the north bank. It was here that, for the only time in his career, Napoleon was slightly wounded. Then, leaving Davout to observe the archduke's retreat, the emperor himself rode after Masséna, who with the major portion of the French army was following the Austrian weaker wing under Hiller. The latter was not so shaken as Napoleon believed, and turning at bay at Ebelsberg inflicted a severe check on its pursuers. Thus covered by his rearguard Hiller gained space and time to pass his troops over to the north bank of the Danube and remove all boats on the river. This left the direct road to Vienna open, and Napoleon, hoping to find peace in the enemy's capital, pushed the whole of his army down the right bank, and with Murat's cavalry entered the city on May 12, after somewhat severe resistance lasting three days. Meanwhile the archduke and Hiller, both now unmolested, effected their junction in the vicinity of Wagram, picketing the whole line of the Danube with their outposts and collecting all the boats.

Aspern and Wagram.—The reconnaissance of the river was at once taken in hand by the French upon their arrival in Vienna, and a point opposite the island of Lobau selected for the crossing.

Thanks to the Austrian precautions it took four days to collect the necessary material to span the main branch of the river, here some 2,000 yd. across, and though Napoleon personally spurred on all to activity nearly four days more were required for its construction. It was not till the night of May 19 that orders for the passage were finally issued, and during the night the troops commenced to occupy the island of Lobau. Surprise, of course, was out of the question, but the Austrians did not attempt to dispute the passage, their object being to allow as many French as they felt they could deal with to pass over and then to fall on them. Thus on May 21 the battle of Aspern (*q.v.*) or Essling began. It ended on the night of the 22nd with the defeat of Napoleon, the first ever inflicted upon him. The French retreated into the island of Lobau. By nightfall upwards of 100,000 men, encumbered with at least 20,000 wounded, were crowded together on the little island scarcely a mile square, short of provisions and entirely destitute of course of all hospital accessories. The question then arose whether the retreat was to be continued across the main stream or not, and for the second time in his career Napoleon assembled his generals to take their opinion. They counselled retreat, but having heard them all he replied, in substance: "If we leave here at all we may as well retire to Strassburg, for unless the enemy is held by the threat of further operations he will be free to strike at our communications and has a shorter distance to go. We must remain here and renew operations as soon as possible."

Immediate orders were despatched to summon every available body of troops to concentrate for the decisive stroke. Practically the lines of communication along the Danube were denuded of combatants, even Bernadotte being called up from Passau, and the viceroy of Italy, who driving the archduke Johann before him (action of Raab) had brought up 56,000 men through Tirol, was disposed towards Pressburg within easy call. The arsenal of Vienna was ransacked for guns, stores and appliances, and preparations in the island pushed on as fast as possible. By the end of June 200,000 troops were stationed within call, and on July 4 the French began to cross over to the left bank of the Danube. The events which followed are described under WAGRAM. The great battle at this place, fought on July 5 and 6, ended in the retirement of the Austrians. The only other event which occurred before peace was made was an unimportant action at Znaim on July 11.

THE RUSSIAN WAR OF 1812

Whilst the campaign of 1809 had shaken the faith of the marshals and the higher ranks in the infallibility of the emperor's judgment, and the slaughter of the troops at Aspern and Wagram had still further accentuated the opposition of the French people to conscription, the result on the fighting discipline of the army had, on the whole, been for good. The panics of Wagram had taught men and officers alike a salutary lesson. Aware of the growing feeling against war in France, Napoleon had determined to make his allies not only bear the expenses of the coming campaign, but find the men as well, and he was so far master of Europe that of the 363,000 who on June 24 crossed the Niemen no less than two-thirds were Germans, Austrians, Poles or Italians. But though the battlefield discipline of the men was better, the discipline in camp and on the march was worse, for the troops were no longer eager to reach the battlefield, and marched because they were compelled, not of their own goodwill. The result was apparent in a sudden diminution in mobility, and a general want of punctuality which seriously influenced the course of the campaign. On the other hand, the Russians, once their fatherland was invaded, became dominated by an ever-growing spirit of fanaticism, and they were by nature too obedient to their natural leaders, and too well inured to the hardships of campaigning, to lose their courage in a retreat.

By the middle of June 1812 the emperor had assembled his army along the line of the Niemen. On the extreme right stood the Austrian contingent under Schwarzenberg (34,000 men). Next, centring about Warsaw, a group of three corps (70,000 men) under the chief command of Napoleon's brother Jerome. Then the main army under Napoleon in person (220,000 men; with 80,000

more under the viceroy of Italy on his right rear); and on the extreme left at Tilsit a flanking corps, comprising the Prussian auxiliary corps and other Germans (in all 40,000 strong). The whole army was particularly strong in cavalry; out of the 450,000, 80,000 belonged to that arm, and Napoleon, mindful of the lessons of 1807, had issued the most minute and detailed orders for the supply service in all its branches, and the forwarding of reinforcements, no less than 100,000 men being destined for that purpose in due course of time.

Information about the Russians was very indifferent; it was only known that Prince Bagration (with 43,000 men) lay grouped about Wolkowsk; Barclay de Tolly (who had about 130,000) about Vilna; and on the Austrian frontier lay a small corps under Tormassov (40,000) in process of formation, while far away on the Turkish frontiers hostilities with the sultan retained Tschitschagov with 50,000 more. Of the enemy's plans Napoleon knew nothing, but, in accordance with his usual practice, the dispositions he had chosen met all immediate possible moves.

Opening of the Campaign.—On June 24 the passage of the Niemen began in torrid heat which lasted for a few days. The main army, with the emperor in person, covered by Murat and the cavalry, moved on Vilna, whilst Jerome on his right rear at once threatened Bagration and covered the emperor's outer flank. From the very first, however, the inherent weakness of the vast army, and the vicious choice of time for the beginning of the advance, began to make themselves felt. With crops still green, and nothing else available as forage for the horses, an epidemic of colic broke out amongst them, and in ten days the mounted arms had lost upwards of one-third of their strength; men died of sunstroke in numbers, and serious straggling began. Still everything pointed to the concentration of the Russians at Vilna, and Jerome, who on July 5 had reached Grodno, was ordered to push on. But Jerome proved quite inadequate to his position, listening to the complaints of his subordinates as to want of supplies and even of pay; he spent four whole days in absolute inertia, notwithstanding the emperor's reprimands. Meanwhile the Russians covered by stubborn rearguards made good their retreat—Barclay towards the entrenched camp of Drissa on the Dvina, Bagration towards Mohilev.

The emperor's first great *coup* thus failed. Jerome was replaced by Davout, and the army resumed its march, this time in the hope of surrounding and overwhelming Barclay, whilst Davout dealt with Bagration. The want of mobility, particularly in the cavalry,

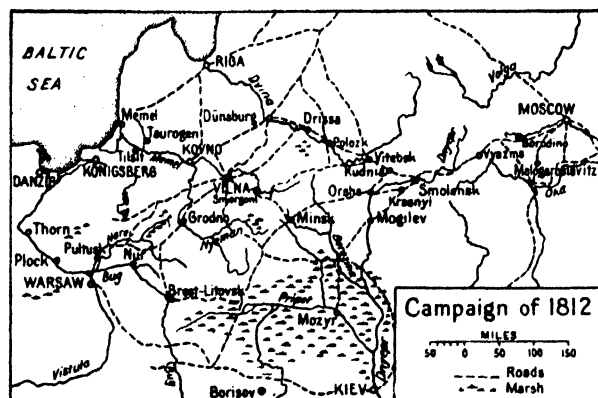

FIG. 7.—CAMPAIGN OF 1812

now began to tell against the French. With horses only just recovering from an epidemic, they proved quite unequal to the task of catching the Cossacks, who swarmed round them in every direction, never accepting an engagement but compelling a constant watchfulness for which nothing in their previous experience had sufficiently prepared the French.

Before their advance, however, the Russian armies steadily retired. Barclay from Vilna via Drissa to Vitebsk, Bagration—narrowly evading Davout—from Wolkowsk to Mohilev. Again arrangements were made for a Napoleonic battle; behind Murat's

cavalry came the "general advanced guard" to attack and hold the enemy, whilst the main body and Davout were held available to swing in on his rear. Napoleon, however, failed to allow for the psychology of his opponents, who refused to be drawn into engagements and steadily withdrew from every position when the French gained touch with them. Thus the manoeuvre against Vitebsk again miscarried, and Napoleon found himself in a far worse position, numerically and materially, than at the outset of the campaign. Then he had stood with 420,000 men on a front of 160m., now he had only 229,000 men on a 135m. front; he had missed three great opportunities of destroying his enemy in detail, and in five weeks, during which time he had only traversed 200m., he had seen his troops reduced numerically at least one-third, and, worse still, his army was now far from being the fighting machine it had been at the outset.

Meanwhile the Russians had not lost a single gun and the *moral* of their men had been improved by the result of the many minor encounters with the enemy; further, the junction of Bagration and Barclay was now assured in the vicinity of Smolensk. Towards this place the French advance was now resumed, and the Russian generals at the head of a united force of 130,000 men marched forward towards Rudnia to meet them. Here, however, the inefficiency of the Russian staff actually saved them from the disaster which must certainly have overtaken them had they realized their intention of fighting the French. The Russians marched in two columns, which lost touch of one another, and as it was quite impossible for either to engage the French single-handed, they both retired again towards Smolensk, where with an advanced guard in the town itself—which possessed an old-fashioned brick *enceinte* not to be breached by field artillery alone—the two columns reunited and deployed for action behind the unfordable Dnieper.

Murat and Ney as "general advanced guard" attacked the town in the morning of Aug. 16, and the main body was swung round to place itself on the Russian rear astride the road to Moscow. The whole of the 17th was required to complete the movement, and as soon as its purpose was sufficiently revealed to the Russians the latter determined to retreat under cover of night. Their manoeuvre was carried out with complete success, and then began a series of rearguard actions and nocturnal retreats which completely accomplished their purpose of wearing down the French army. The Russian government, however, failed to see the matter in its true light, and Marshal Kutusov was sent to the front to assume the chief command. His intention was to occupy a strong position and fight one general action for the possession of Moscow, and to this end he selected the line of the Kalatscha where the stream intersects the great Moscow road.

Borodino.—Here he was overtaken by Murat and Ney, but the French columns had straggled so badly that four whole days elapsed before the emperor was able to concentrate his army for battle and then could only oppose 128,000 men to the Russians' 110,000. About 6 A.M. on Sept. 7 the battle (*see BORODINO*) began, but Napoleon was suffering from one of those attacks of illness and depression which henceforth became such an important factor in his fate. Till about midday he followed the course of the action with his usual alertness; then he appears to have been overcome by a kind of stupor and allowed his marshals to fight by themselves. There was no final decisive effort as at Wagram and the Guard was not even called on to move. Ultimately the sun went down on an undecided field on which 38,000 Russians and 25,000 French had fallen, but the moral reaction on the latter was far greater than on the former. Kutusov continued his retreat, and Murat with his now exhausted horsemen followed as best he might. Sebastiani, commanding the advanced guard, overtook the Russians in the act of evacuating Moscow, and agreed with the latter to observe a seven hours' armistice to allow the Russians to clear the town, for experience had shown the French that street fighting in wooden Russian townships always meant fire and the consequent destruction of much-needed shelter and provisions. Towards nightfall Napoleon reached the scene, and the Russians being now clear the troops began to enter, but already fires were observed in the farther part of the city. Napoleon passed the night in a house in the western suburb and next morning rode to

the Kremlin, the troops moving to the quarters assigned to them, but in the afternoon a great fire began and, continuing for two days, drove the French out into the country again.

The emperor was now in the direst perplexity. Kutusov was hovering on the outskirts of the city, his main body at Kaluga, some marches to the south-west, where he was in full communication with the richest portion of the empire; and now news arrived that St. Cyr, who had relieved Macdonald on his extreme left, had only 17,000 men left under arms against upwards of 40,000 Russians under Witgenstein; and to the south Tschitschagov's army, being no longer detained on the Turkish frontier, where peace had been made, was marching to join Tormassov about Brest-Litovsk with forces which would bring the total of the two well over 100,000 men. Meanwhile Schwarzenberg's force opposing these had dwindled to a bare 30,000.

The French army was thus disposed almost in an equilateral triangle with sides of about 570m., with 95,000 men at the apex at Moscow opposed to 120,000, 30,000 about Brest opposite 100,000, and 17,000 about Drissa confronted by 40,000, whilst in the centre of the base at Smolensk lay Victor's corps, about 30,000. From Moscow to the Niemen was 550 miles. In view of this situation Napoleon on Oct. 4 sent General Lauriston to the Russian headquarters to treat. While waiting his return Murat was enjoined to skirmish with Kutusov, and the emperor himself worked out a scheme to assume the offensive with his whole army towards St. Petersburg, calling in Victor and St. Cyr on the way. This project was persisted with, until on the 18th Murat was himself attacked and severely handled (action of Tarutino or Vinkovo). On the morning of the 19th the whole army moved out to accept this challenge, and the French were thoroughly worsted on the 24th in the battle of Maloyaroslavetz.

The Retreat from Moscow.—Then began the celebrated retreat. It has generally been forgotten that the utter want of march discipline in the French, and not the climatic conditions, was responsible for the appalling disasters which ensued. Actually the frost came later than usual that year, Oct. 27, and the weather was dry and bracing; not till Nov. 8 did the cold at night become sharp. Even when the Beresina was reached on Nov. 26, the cold was far from severe, for the slow and sluggish stream was not frozen over, as is proved by the fact that Eblé's pioneers worked in the water all through that terrible day. But the French army was already completely out of hand, and the degree to which the panic of a crowd can master even the strongest instinct of the individual is shown by the conduct of the fugitives who crowded over the bridges, treading hundreds under foot, whilst all the time the river was easily fordable and mounted men rode backwards and forwards across it.

To return to the actual sequence of events. Kutusov had been very slow in exploiting his success of the 24th and indeed had begun the pursuit in a false direction; but about Nov. 2, headquarters of the French being at Vyazma, the Cossacks became so threatening that the emperor ordered the army to march (as in Egypt) in hollow square. This order, however, appears only to have been obeyed by the Guards, with whom henceforward the emperor marched.

Kutusov had now overtaken the French, but fortunately for them he made no effort to close with them, but hung on their flank, molesting them with Cossacks and picking up stragglers. Thus the wreck of the *Grande Armée*, now not more than fifty thousand strong, reached Smolensk on the 9th and there rested till the 14th. The march was then resumed, the Guard leading and Ney commanding the rearguard. Near Krasnoi on the 16th the Russian advanced guard tried to head the column off. Napoleon halted a whole day to let the army close up; and then attacked with his old vigour and succeeded in clearing the road, but only at the cost of leaving Ney and the rearguard to its fate. By a night march of unexampled daring and difficulty Ney succeeded in breaking through the Russian cordon, but when he regained touch with the main body at Orcha only 800 of his 6,000 men were still with him (21st).

The Beresina.—From here Napoleon despatched orders to Victor to join him at Borisov on the Beresina. The cold now gave

way and thaw set in, leaving the country a morass, and information came that Tschitschagov from the south had reached Borisov. He now selected Viesselovo as the point of passage and at 1 A.M. on the 23rd sent orders to Oudinot to march thither and construct bridges. In the execution of these orders Oudinot encountered the Russian advanced guard near Borisov and drove the latter back in confusion, though not before they had destroyed the existing bridge there. This sudden reassumption of the offensive threw Tschitschagov into confusion. Thus time was gained for Victor also to come up and for Oudinot to construct the bridges at Studienka near the above-mentioned place, but a spot in many respects better suited for the purpose. Thither therefore Napoleon sent his pontonniers under General Eblé, but on their arrival they found that no preparations had been made and much time was lost. Meanwhile Victor, in doubt as to the real point of passage, had left the road to Studienka open to Wittgenstein, who had followed hard on his heels.

By 4 P.M. on the 26th the bridges were finished and the passage began, but not without resistance by the Russians, who were gradually closing in. The crossing continued all night, though interrupted from time to time by failures of the bridges. All day during the 27th stragglers continued to cross, covered by such combatants as remained under sufficient discipline to be employed. At 8 A.M. on the 28th, however, Tschitschagov and Wittgenstein moved forward on both banks of the river to the attack, but were held off by the splendid self-sacrifice of the few remaining troops under Ney, Oudinot and Victor, until about 1 P.M. the last body of regular troops passed over the bridges, and only a few thousand stragglers remained beyond the river.

The number of troops engaged by the French that day cannot be given exactly. Oudinot's and Victor's men were relatively fresh and may have totalled 20,000, whilst Ney can hardly have had more than 6,000 of all corps fighting under him. How many were killed can never be known, but three days later the total number of men reported fit for duty had fallen to 8,800 only.

Final Operations.—Henceforward the retreat of the army became practically a headlong flight, and on Dec. 8, having reached Smorgoni and seeing that nothing further could be done by him at the front, the emperor handed over the command of what remained to Murat, and left for Paris to organize a fresh army for the following year. Travelling at the fullest speed, he reached the Tuileries on the 18th, after a journey of 312 hours. After the emperor's departure the cold set in with increased severity, the thermometer falling to 23°. On Dec. 8, Murat reached Vilna, whilst Ney with about 400 men and Wrede with 2,000 Bavarians still formed the rearguard; but it was quite impossible to carry out Napoleon's instructions to go into winter quarters about the town, so that the retreat was resumed on the 10th and ultimately Königsberg was attained on Dec. 19 by Murat with 400 Guards and 600 Guard cavalry dismounted. Meanwhile on the extreme French right Schwarzenberg and his Austrians had drifted away towards their own frontier, and the Prussian contingent, which under Yorck formed part of Macdonald's command about Riga, had entered into a convention with the Russians at Tauroggen (Dec. 30) which deprived the French of the last support upon their left. Königsberg thus became untenable, and Murat fell back to Posen, where on Jan. 10 he handed over his command to Eugène Beauharnais and returned to Paris. The Russian pursuit practically ceased at the line of the Niemen, for the Russian troops also had suffered terrible hardships and a period of rest had become an absolute necessity.

The War of Liberation.—The Convention of Tauroggen became the starting-point of Prussia's regeneration. As the news of the destruction of the *Grande Armée* spread, and the appearance of countless stragglers convinced the Prussian people of the reality of the disaster, the spirit generated by years of French domination burst out. For the moment the king and his ministers were placed in a position of the greatest anxiety, for they knew the resources of France and the boundless versatility of their arch-enemy far too well to imagine that the end of their sufferings was yet in sight. To disavow the acts and desires of the army and of the secret societies for defence with which all north Germany was honey-

combed would be to imperil the very existence of the monarchy, whilst an attack on the wreck of the *Grande Armée* meant the certainty of a terrible retribution from the new armies now rapidly forming on the Rhine.

But the Russians and the soldiers were resolved to continue the campaign, and working in collusion they put pressure on the unwilling representatives of the civil power to facilitate the supply

FIG. 8.—CAMPAIGN OF 1813

and equipment of such troops as were still in the field; they could not refuse food and shelter to their starving countrymen or their loyal allies, and thus by degrees the French garrisons scattered about the country either found themselves surrounded or were compelled to retire to avoid that fate. Thus it happened that the viceroy of Italy felt himself compelled to depart from the positive injunctions of the emperor to hold on at all costs to his advanced position at Posen, where about 14,000 men had gradually rallied around him, and to withdraw step by step to Magdeburg, where he met reinforcements and commanded the whole course of the lower Elbe.

Napoleon's Preparations.—Meanwhile the emperor in Paris had been organizing a fresh army for the reconquest of Prussia. Thanks to his having compelled his allies to fight his battles for him, he had not as yet drawn very heavily on the fighting resources of France, the actual percentage of men taken by the conscriptions during the years since 1806 being actually lower than that in force in continental armies of the early twentieth century. He had also created in 1811-12 a new National Guard, organized in "cohorts" to distinguish it from the regular army, and for home defence only, and these by a skilful appeal to their patriotism and judicious pressure applied through the prefects, became a useful reservoir of half-trained men for new battalions of the active army. Levies were also made with rigorous severity in the states of the Rhine Confederation, and even Italy was called on for fresh sacrifices. In this manner by the end of March upwards of 200,000 men were moving towards the Elbe,¹ and in the first fortnight of April they were duly concentrated in the angle formed by the Elbe and Saale, threatening on the one hand Berlin, on the other Dresden and the east.

The allies, aware of the gradual strengthening of their enemy's forces but themselves as yet unable to put more than 200,000 in the field, had left a small corps of observation opposite Magdeburg and along the Elbe to give timely notice of an advance towards Berlin; and with the bulk of their forces had taken up a position about Dresden, whence they had determined to march down the course of the Elbe and roll up the French from right to left. Both armies were very indifferently supplied with information, as both were without any reliable regular cavalry capable of piercing the screen of outposts with which each endeavoured to conceal his disposition, and Napoleon, operating in a most unfriendly country, suffered more in this respect than his adversaries.

¹ Napoleon always gave their number as 300,000, but this was never attained.

On April 25 Napoleon reached Erfurt and assumed the chief command. On this day his troops stood in the following positions: Eugène, with Lauriston's, Macdonald's and Regnier's corps, on the lower Saale; Ney in front of Weimar, holding the defile of Kösen; the Guard at Erfurt, Marmont at Gotha, Bertrand at Saalfeld, and Oudinot at Coburg, and during the next few days the whole were set in motion towards Merseburg and Leipzig, in the now stereotyped Napoleonic order, a strong advanced guard of all arms leading, the remainder—about two-thirds of the whole—following as *masse de manoeuvre*, this time, owing to the cover afforded by the Elbe on the left, to the right rear of the advanced guard.

Meanwhile the Russians and Prussians had concentrated all available men and were moving on an almost parallel line, but somewhat to the south of the direction taken by the French. On May 1 Napoleon and the advance guard entered Lützen. Wittgenstein, who now commanded the allies in place of Kutusov, hearing of his approach, had decided to attack the French advanced guard, which he took to be their whole force, on its right flank, and during the morning had drawn together the bulk of his forces on his right in the vicinity of Gross-Görschen and Kaya.

Battle of Lützen.—About 9 A.M. on May 2 he began an attack on the French advance guard in Lützen, whilst the remainder of his army was directed against Napoleon's right and rear. Just as the latter were moving off the heads of the French main body suddenly appeared, and at 11 A.M. Napoleon, then standing near the Gustavus Adolphus monument on the field of Lützen, heard the roar of a heavy cannonade to his right rear. He realized the situation in a moment, galloped to the new scene of action, and at once grouped his forces for decisive action—the gift in which he was supreme. Leaving the leading troops to repulse as best they might the furious attack of both Russians and Prussians, and caring little whether they lost ground, he rapidly organized for his own control a battle-reserve. At length when both sides were exhausted by their efforts he sent forward nearly a hundred guns which tore asunder by their case-shot fire the enemy's line and marched his reserve right through the gap. Had he possessed an adequate cavalry force the victory would have been decisive. As it was, the allies made good their retreat and the French were too exhausted for infantry pursuit.

Perhaps no battle better exemplifies the inherent strength of the emperor's strategy, and in none was his grasp of the battlefield more brilliantly displayed, for, as he fully recognized, "These Prussians have at last learnt something—they are no longer the wooden toys of Frederick the Great," and, on the other hand, the relative inferiority of his own men as compared with his veterans of Austerlitz called for far more individual effort than on any previous day. He was everywhere, encouraging and compelling his men—it is a legend in the French army that the persuasion even of the imperial boot was used upon some of his reluctant conscripts, and in the result his system was fully justified, as it triumphed even against a great tactical surprise.

Bautzen.—As soon as possible the army pressed on in pursuit, Ney being sent across the Elbe to turn the position of the allies at Dresden. This threat forced the latter to evacuate the town and retire over the Elbe, before blowing up the stone bridge across the river. Napoleon entered the town hard on their heels, but the broken bridge caused a delay of four days, there being no pontoon trains with the army. Ultimately on May 18 the march was renewed, but the allies had continued their retreat in leisurely fashion, picking up reinforcements by the way. Arrived at the line of the Spree, they took up and fortified a very formidable position about Bautzen (*q.v.*). Here, on the 20th, they were attacked and fixed by Napoleon; but the intended decisive coup by which Ney was to arrive on their right rear on the 21st missed its mark owing to Ney's want of initiative and rigid adherence to the letter of his orders. As a result the allies were able to break off the action at their own time and retire in such good order that the emperor failed to capture a single trophy as proof of his victory. The enemy's escape annoyed him greatly, the absence of captured guns and prisoners reminded him too much of his Russian experiences, and he redoubled his demands on his corps

commanders for greater vigour in the pursuit. This led the latter to push on without due regard to tactical precautions, and Blücher took advantage of their carelessness when at Haynau (May 26), with some twenty squadrons of Landwehr cavalry, he surprised, rode over and almost destroyed Maison's division. The material loss inflicted on the French was not very great, but its effect in raising the *moral* of the raw Prussian cavalry and increasing their confidence in their old commander was enormous.

Still the allies continued their retreat and the French were unable to bring them to action. In view of the doubtful attitude of Austria, Napoleon became alarmed at the gradual lengthening of his lines of communication and opened negotiations. The enemy, having everything to gain and nothing to lose thereby, agreed finally to a six weeks' suspension of arms. This was perhaps the gravest military error of Napoleon's whole career, and his excuse for it, "want of adequate cavalry," was the strongest testimony as to the value of that arm.

As soon as a suspension of arms (to Aug. 15) had been agreed to, Napoleon hastened to withdraw his troops from the dangerous position they occupied with reference to the passes leading over the mountains from Bohemia, for he entertained no doubt now that Austria was also to be considered as an enemy. Finally he decided to group his corps round Görlitz and Bautzen whence they could either meet the enemy advancing from Breslau or fall on his flank over the mountains if he attempted to force his way into Saxony by the valley of the Elbe. This latter manoeuvre depended, however, on his maintenance of Dresden, and to this end he sent the I. Corps up the Elbe to Pirna and Königstein to cover the fortifications of Dresden itself. His instructions on this point deserve the closest study, for he foresaw the inevitable attraction which a complete entrenched camp would exercise even upon himself, and, therefore, limited his engineers to the construction of a strong bridge head on the right bank and a continuous enceinte, broken only by gaps for counter attack, around the town itself.

Then he turned his attention to the plan for the coming campaign. Seeing clearly that his want of an efficient cavalry precluded all ideas of a resolute offensive in his old style, he determined to limit himself to a defence of the line of the Elbe, a position of waiting from which he could make a spring, of not more than a few days' duration, at any target the enemy might present.

Reinforcements had been coming up without ceasing and at the beginning of August he calculated that he would have 300,000 men available about Bautzen and 100,000 along the Elbe from Hamburg via Magdeburg to Torgau. With the latter he determined to strike the first blow, by a concentric advance on Berlin (which he calculated he would reach on the 4th or 5th day), the movement being continued thence to extricate the French garrisons in Küstrin, Stettin and Danzig. The moral effect, he promised himself, would be prodigious, and there was neither room nor food for these 100,000 elsewhere. Towards the close of the armistice he learned the general situation of the allies. The crown prince of Sweden (Bernadotte), with his Swedes and various Prussian levies, 135,000 in all, lay in and around Berlin and Stettin; and knowing his former marshal well, Napoleon considered Oudinot a match for him. Blücher with about 95,000 Russians and Prussians was about Breslau, and Schwarzenberg, with nearly 180,000 Austrians and Russians, lay in Bohemia. In his central position at Bautzen he felt himself equal to all his enemy's combinations.

Dresden.—The advance towards Berlin began punctually with the expiration of the armistice, but with the main army he himself waited to see more clearly his adversaries' plans. At length becoming impatient he advanced a portion of his army towards Blücher, who fell back to draw him into a trap. Then the news reached him that Schwarzenberg was pressing down the valley of the Elbe, and, leaving Macdonald to observe Blücher, he hurried back to Bautzen to dispose his troops to cross the Bohemian mountains in the general direction of Königstein, a blow which would have had decisive results. But the news from Dresden, where the construction of the defences was still incomplete, was so alarming that at the last moment he changed his mind, and

sending Vandamme alone over the mountains, he hurried with his whole army to the threatened point. This march remains one of the most extraordinary in history, for the bulk of his forces moved, mainly in mass and across country, 90m. in 72 hours, entering Dresden on the morning of the 27th, only a few hours before the attack of the allies commenced. For the events which followed see *DRESDEN (battle)*.

Dresden was the last great victory of the First Empire. By noon on Aug. 27 the Austrians and Russians were completely beaten and in full retreat, the French pressing hard behind them, but meanwhile Napoleon himself again succumbed to one of his unaccountable attacks of apparent intellectual paralysis. He seemed unaware of the vital importance of the moment, crouched shivering over a bivouac fire, and finally rode back to Dresden, leaving no specific orders for the further pursuit. The allies, however, continued to retreat, but unfortunately Vandamme, with his single corps and unsupported, issued out of the mountains on their flank, threw himself across their line of retreat near Kuhl, and was completely overwhelmed by sheer weight of numbers (29th). In spite of this misfortune, Napoleon could claim a brilliant success for himself, but almost at the same moment news reached him that Oudinot at Grossbeeren near Berlin, and Macdonald on the Katzbach opposed to Blücher, had both been severely defeated.

Napoleon's Movements.—During the next two days the emperor examined his situation and, after discussing on paper the respective hypotheses of a spring at Prague or at Berlin, summed up in favour of the second. But his consideration of this project was interrupted by news which indicated that the consequences of Macdonald's defeat had been far more serious to the *moral* of that command than he had imagined. He immediately rode over to establish order, and his manner and violence were so improper that Caulaincourt had the greatest difficulty in concealing the scandal. Blücher, however, hearing of his arrival, at once retreated and the emperor followed, thus uncovering the passes over the Bohemian mountains, a fact of which Schwarzenberg was quick to take advantage. Learning of his approach, Napoleon again withdrew to Bautzen. Then hearing that the Austrians had counter-marched and were again moving towards Dresden, he hastened back there, concentrated as many men as could conveniently be handled, and advanced beyond Pirna and Königstein to meet him. But the Austrians had no intention of attacking him, for time was now working on their side and, leaving his men to starve in the exhausted district, the emperor again returned to Dresden, where for the rest of the month he remained in an extraordinary state of vacillation. On Oct. 4 he again drew up a review of the situation, in which he apparently contemplated giving up his communications with France and wintering in and around Dresden, though at the same time he was aware of the distress amongst his men for want of food.

Campaign of Leipzig.—In the meanwhile Blücher, Schwarzenberg and Bernadotte were working round his flanks. Ney, who had joined Oudinot after Grossbeeren, had been defeated at Dennewitz (Sept. 6), the victory, won by Prussian troops solely, giving the greatest encouragement to the enemy. Suddenly Napoleon's plans are again reviewed and completely changed. Calling up St. Cyr, whom he had already warned to remain at Dresden with his command, he decided to fall back towards Erfurt, and go into winter quarters between that place and Magdeburg, pointing out that Dresden was of no use to him as a base and that if he had a battle, he had much better have St. Cyr and his men with him than at Dresden. He then on Oct. 7 drew up a final plan, and this he immediately proceeded to put into execution, for he was now aware of the danger threatening his line of retreat from both Blücher and Schwarzenberg and the North Army; yet only a few hours afterwards the portion of the order relating to St. Cyr and Lobau was cancelled and the two were finally left behind at Dresden. From the 10th to the 13th Napoleon lay at Düben, again a prey to the most extraordinary irresolution, but on that day he thought he saw his opportunity. Blücher was reported near Wittenberg, and Schwarzenberg was moving slowly round to the south of Leipzig. The North Army under Bernadotte, unknown to Napoleon, lay on Blücher's left

around Halle. The emperor decided to throw the bulk of his force on Blücher, and, having routed him, turn south on Schwarzenberg and sever his communications with Bohemia. His concentration was effected with his usual sureness and celerity, but whilst the French moved on Wittenberg, Blücher was marching to his right, indifferent to his communications as all Prussia lay behind him. This move on the 14th brought him into touch with Bernadotte, and now a single march forward of all three armies would have absolutely isolated Napoleon from France; but Bernadotte's nerve failed him, for on hearing of Napoleon's threat against Wittenberg he decided to retreat northward, and not all the persuasions of Blücher and Gneisenau could move him. Thus if the French movement momentarily ended in a blow in the air, it was indirectly the cause of their ultimate salvation.

The "Battle of the Nations."—On the 15th Napoleon concentrated his forces to the east of Leipzig, with only a weak detachment to the west, and in the evening the allies were prepared to attack him. Schwarzenberg had 180,000 men available at once and 60,000 on the following day; Blücher had about 60,000, but Bernadotte now could not arrive before the 18th.

Napoleon prepared to throw the bulk of his force upon Schwarzenberg and massed his troops south-east of the town, whilst Schwarzenberg marched concentrically against him down the valleys of the Elster and Pleisse, the mass of his troops on the right bank of the latter and a strong column under Giulay on the left working round to join Blücher on the north. The fighting which followed was most obstinate, but the Austrians failed to make any impression on the French positions, and indeed Giulay felt himself compelled to withdraw to his former position. On the other hand, Blücher carried the village of Möckern and came within a mile of the gates of the town. During the 17th there was only indecisive skirmishing, Schwarzenberg waiting for his reinforcements coming up by the Dresden road, Blücher for Bernadotte to come in on his left, and by some extraordinary oversight Giulay was brought closer in to the Austrian centre, thus opening for the French their line of retreat towards Erfurt, and no information of this movement appears to have been conveyed to Blücher. The emperor when he became aware of the movement, sent the IV. corps to Lindenau to keep the road open. On the 18th the fighting was resumed and by about noon Bernadotte came up and closed the gap to the N.E. of the town between Blücher and the Austrians. At 2 P.M. the Saxons, who had remained faithful to Napoleon longer than his other German allies, went over to the enemy. All hope of saving the battle had now to be given up, but the French covered their retreat obstinately and by daybreak next morning one-half of the army was already filing out along the road to Erfurt which had so fortunately been left for them.

It took Blücher time to extricate his troops from the confusion into which the battle had thrown them, and the garrison of Leipzig and the troops left on the right bank of the Elster still resisted obstinately—hence no direct pursuit could be initiated, and the French, still upwards of 100,000 strong, marching rapidly, soon gained distance enough to be reformed. Blücher followed by parallel and inferior roads on their northern flank, but Schwarzenberg knowing that the Bavarians also had forsaken the emperor and were marching under Wrede, 50,000 strong, to intercept his retreat, followed in a most leisurely fashion. Blücher did not succeed in overtaking the French, but the latter, near Hanau, found their way barred by Wrede with 50,000 men and over 100 guns in a strong position. To this fresh emergency Napoleon and his army responded in most brilliant fashion. As at Krasnoi in 1812, they went straight for their enemy and after one of the most brilliant series of artillery movements in history, directed by General Drouot, they marched right over their enemy, practically destroying his whole force. Henceforward their march was unmolested, and they reached Mainz on Nov. 5.

THE CAMPAIGN IN FRANCE IN 1814

When the last of the French troops had crossed to the western bank of the Rhine, divided counsels made their appearance at the headquarters of the allies. Everyone was weary of the war, and

many felt that it would be unwise to push Napoleon and the French nation to extremes. Hence a prolonged halt arose, utilized by the troops in renewing their equipment and so forth, but ultimately the Young German party, led by Blücher and the principal fighting men of the army, triumphed, and on Jan. 1, 1814, the Silesian army (50,000) began its passage of the Rhine at Kaub. They were to be supported by Schwarzenberg with 200,000 men,

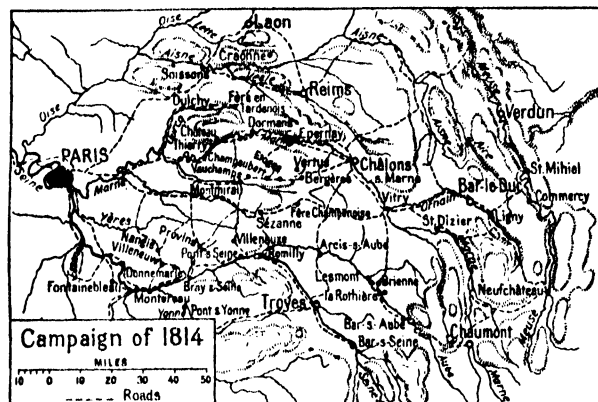

FIG. 9.—CAMPAIGN OF 1814

who was to advance by Basel and Neu Breisach to the south, and Bernadotte with the Northern army, about 120,000, was to move in support on the right flank through the Netherlands and Laon; this force was not yet ready and did not, in fact, reach the latter place till March. To meet these forces the emperor could not collect 200,000 men in all, of whom upwards of 100,000 were held by Wellington on the Spanish frontier, and 20,000 more were required to watch the debouches from the Alps. Hence less than 80,000 remained available for the east and north-eastern frontier. If, however, he was weak in numbers, he was now again operating in a friendly country, able to find food almost everywhere and practically indifferent as to his communications.

On Jan. 25 Blücher entered Nancy, and, moving rapidly up the valley of the Moselle, was in communication with the Austrian advanced guard near La Rothière on the afternoon of the 28th. Here his headquarters were surprised and he himself nearly captured by a sudden rush of French troops, and he learnt at the same time that the emperor in person was at hand. He accordingly fell back a few miles next morning to a strong position covering the exits from the Bar-sur-Aube defile. There he was joined by the Austrian advance guard, and together they decided to accept battle—indeed they had no alternative, as the roads in rear were so choked with traffic that retreat was out of the question. About noon Feb. 2 Napoleon attacked them, but the weather was terrible, and the ground so heavy that his favourite artillery, the mainstay of his whole system of warfare, was useless and in the drifts of snow which at intervals swept across the field, the columns lost their direction and many were severely handled by the Cossacks. At nightfall the fighting ceased and the emperor retired to Lesmont, and thence to Troyes, Marmont being left to observe the enemy.

Montmirail.—Owing to the state of the roads, more perhaps to the extraordinary lethargy which always characterized Schwarzenberg's headquarters, no pursuit was attempted. But on Feb. 4 Blücher, chafing at this inaction, obtained the permission of his own sovereign to transfer his line of operations to the valley of the Marne; Pahlen's corps of Cossacks were assigned to him to cover his left and maintain communication with the Austrians. Believing himself secure behind this screen, he advanced from Vitry along the roads leading down the valley of the Marne, with his columns widely separated for convenience of subsistence and shelter—the latter being almost essential in the terrible weather prevailing. Blücher himself on the night of the 7th was at Sézanne, on the exposed flank so as to be nearer to his sources of intelligence, and the rest of his army were distributed in four small corps at or near Épernay. Montmirail and Étoges; reinforcements

also were on their way to join him and were then about Vitry.

In the night his headquarters were again surprised, and he learnt that Napoleon himself with his main body was in full march to fall on his scattered detachments. At the same time he heard that Pahlen's Cossacks had been withdrawn forty-eight hours previously, thus completely exposing his flank. He himself retreated towards Étoges endeavouring to rally his scattered detachments, but Napoleon was too quick for him and in three successive days he defeated Sacken at Montmirail, Yorck at Champ Aubert and Blücher and his main body at Étoges, pursuing the latter towards Vertus. These disasters compelled the retreat of the whole Silesian army, and Napoleon, leaving Mortier and Marmont to deal with them, hurried back to Troyes with his main body to strike the flank of Schwarzenberg's army, which had meanwhile begun its leisurely advance, and again at Mormant on Feb. 17, Montereau the 18th and Méry the 21st, he inflicted such heavy punishment upon his adversaries that they fell back precipitately to Bar-sur-Aube.

In the meantime Blücher had rallied his scattered forces and was driving Marmont and Mortier before him. Napoleon, as soon as he had disembarrassed himself of Schwarzenberg, counter-marched his main body and moving again by Sézanne, fell upon Blücher's left and drove him back upon Soissons. This place had been held by a French garrison, but had capitulated only twenty-four hours beforehand, a fact of which Napoleon was naturally unaware. The Silesian army was thus able to escape, and marching northwards combined with Bernadotte at Laon—this reinforcement bringing the forces at Blücher's disposal up to over 100,000 men. On March 7 Napoleon fell upon the advance guard of this force at Craonne and drove it back upon Laon, where a battle took place on the 9th. Napoleon was here defeated, and with only 30,000 men at his back he was compelled to renounce all ideas of a further offensive, and he retired to rest his troops at Reims. Here he remained unmolested for a few days, for Blücher was struck down by sickness, and in his absence nothing was done. On March 14, however, Schwarzenberg, becoming aware of Napoleon's withdrawal to Reims, again began his advance and had reached Arcis-sur-Aube when the news of Napoleon's approach again induced him to retreat to Brienne.

The Allies March on Paris.—Thus after six weeks' fighting the allies were hardly more advanced than at the beginning. Now, however, they began to realize the weakness of their opponent, and, still more, the weakening of his political stability. Napoleon, coincidentally, aware of the limitations of a strategy of continual parrying, was seized with the idea of a decisive coup against Schwarzenberg's communications. He determined to move eastward to St. Dizier, rally what garrisons he could find, and raise the whole country against the invaders, and had actually started on the execution of this plan when his instructions fell into the enemy's hands and his projects were exposed. The Czar Alexander called a council of war at which General Toll in opposition to his seniors, urged that instead of following Napoleon the allies should disregard the threat to their rear and advance by forced marches on Paris, whose people were reported to be "tired of the war and of Napoleon." His arguments for this moral objective won over the Czar and at his instigation the allies marched straight for the capital. Marmont and Mortier with what troops they could rally took up a position on Montmartre heights to oppose them, but seeing further resistance to be hopeless they gave way on March 31, just as Napoleon, with the wreck of the Guards and a mere handful of other detachments, was hurrying across the rear of the Austrians towards Fontainebleau to join them.

This was the end of the First Empire. The story of the WATERLOO CAMPAIGN is told under its own heading.

BIBLIOGRAPHY.—Among the principal modern works on Napoleon's campaigns 1805-14 are the following: Yorck von Wartenberg, *Napoleon als Feldherr* (1866, English and French translations); H. Camon, *La Guerre napoléonienne* (Paris, 1903); H. Bonnal, *Esprit de la guerre moderne* (a series of works, of which those dealing with 1805-1812 are separately mentioned below). For 1805 see Alombert and Collin (French Gen. Staff), *Campagne de 1805 en Allemagne* (Paris, 1898-1910); H. Bonnal, *De Rosbach à Ulm* (Paris, 1903); G. A. Furse, *Ulm, Trafalgar and Austerlitz* (London, 1905). For 1806-1807, Pr. Kraft zu Hohenlohe-Ingelfingen, *Letters on Strategy* (Eng. trans., vol.

i.); Freiherr v. d. Goltz, *Von Rossbach bis Jena und Auerstädt* (Berlin, 1906) and *Von Jena bis Preussisch-Eylau* (Berlin, 1908); H. Bonnal, *La Manoeuvre d'Iéna* (Paris, 1904); *Memoirs of Bennigsen* (trans. by E. Cazalas, French Gen. Staff, 1909); F. N. Maude, *The Jena Campaign* (London, 1909). For 1809, H. Bonnal, *La Manoeuvre de Landshut* (Paris, 1905); Sasaki, *Campagne de 1809* (Paris, 1899-1902); Ritter v. Angeli, *Erzherzog Karl* (Vienna, 1895-1897); Lieut. Field Marshal von Woinovich (ed.), *Das Kriegsjahr 1809*; Buat, *De Ratisbonne à Znadim* (Paris, 1910). For 1812, G. Fabry (French Gen. Staff), *Campagne de 1812* (Paris, 1904); *La Guerre nationale de 1812* (French translation from the Russian general staff work, Paris, 1904); H. NAVAL OPERATIONS

The Peace of Amiens in 1802 was productive of but a brief truce. Napoleon's ambitions and actions were such as quickly to re-awaken European suspicions, and his refusal to evacuate the Netherlands was alone enough to arouse England and cause her to declare war on him as early as May 18, 1803. From then onwards, for over two years, the war took the form of a gigantic scheme, on the part of Napoleon, for an invasion of England—a scheme which led to the movements known as the Trafalgar Campaign which, in its turn, led to the Battle of Trafalgar. Boulogne was chosen as the base for the French operations; along the coast on either side an army of some 150,000 men was encamped, and specially-constructed flat-bottomed boats for their transport were brought from all parts of France. The army was given constant practice in embarkation and disembarkation, and, in the meantime, it proved impossible for the British ships to do much damage to this armament owing to the shallow water on the coastline. In order, however, to carry through his scheme successfully, Napoleon had got to obtain at least a temporary control of the Channel, and this meant either defeating the British fleet on equal terms in action, or, by some means, causing the various parts of it to scatter on some wild-goose chase, so giving himself the chance to bring every available ship to the Channel and overwhelm the British fleet there by sheer weight of numbers. French fleets were stationed at Brest, Rochefort, L'Orient and Toulon; all of them were watched by British blockading squadrons. From the end of 1804, when Spain entered the war on his side, Napoleon was able to add to this total Spanish squadrons at Corunna, Ferrol, Cadiz and Cartagena, all of which the British blockaded. The total number of ships at Napoleon's command was about 60, the English had an approximately equal number employed in blockading them. His plan, then, took the form of attempting to elude these blockading squadrons and make them scatter to various parts of the world in search of his escaped squadrons which would, after concentrating at a given rendez-vous, return to the Channel to crush Cornwallis and the English Channel Fleet, if indeed that had not scattered too, after the presumed escape of the Brest Fleet which it was blockading. In either case Napoleon might hope to achieve his object—control of the Channel for long enough to enable him to take his troops across, while the British squadrons returned from the various parts of the world to which he seemed to think they might sail. The scheme was an exceedingly weak one, and postulated a gross ignorance of naval strategy on the part of that country that had been its greatest exponent. The British Admiralty upset it by a single order. The various blockading squadrons, if they were eluded by the squadrons they were blockading, were to fall back on Cornwallis. Thus if all the French squadrons united at the appointed rendez-vous (which was Martinique) and sailed for the Channel, they would merely find Cornwallis with an equally concentrated fleet, and the extent of the British concentration would depend on, and be equal to, that of the French.

The first move occurred in January 1805 when the Rochefort

but it proved an isolated effort. On March 30, however, Admiral Villeneuve used a gale to elude Nelson who was watching him off Toulon, and got clear away with eleven ships which he increased to eighteen by picking up the Cadiz Squadron, reaching Martinique on May 14. He was joined on June 1, by two ships from Rochefort, but no others put in an appearance. He should have waited until nearly the end of the month before sailing back to Europe to try and pick up those squadrons which failed to join him, preliminary to making for Brest, whence Admiral Ganteaume was trying unsuccessfully to emerge from time to time. Only a week later, however, information reached Villeneuve that Nelson was already in the West Indies in search of him, and he decided to make for European waters immediately. Nelson, after having been evaded off Toulon should, according to his orders, have fallen back on Cornwallis, but he preferred, not for the first time, to follow his own course. It has often been said that Villeneuve induced Nelson to follow him and that, in doing so, the latter was playing into Napoleon's hands. The foolishness of this can be seen in the fact that the mere information that Nelson was in the neighbourhood caused Villeneuve to make for home a considerable time before he was due to depart, and any hope of a West Indian concentration was thus lost. When Napoleon hoped that the English blockading squadrons would scatter, he meant to places where the French had not gone. Foiled by false information of his hope of catching Villeneuve, Nelson sent a fast brig home to warn the Admiralty of the former's return, and himself sailed for Gibraltar. The Admiralty despatched Sir Robert Calder to intercept Villeneuve; this he did, off Finisterre, and, in a not very satisfactory action, fought in a fog, deprived him of two Spanish battleships, but let him make Ferrol. Here the French Admiral received reinforcements, and his next move, according to his programme, should have been to make for the Channel in an attempt to unite with the Brest fleet. But he conceived, rightly, that Napoleon's scheme had already been foiled and that his task would be impossible; thus when he left Ferrol he made, not for the Channel, but for Cadiz. Here he was blockaded by Nelson and Collingwood. The Trafalgar Campaign, as a campaign, was over, and the invasion scheme was a failure. Napoleon broke up his camp and marched his troops against Austria. A natural corollary of the Trafalgar Campaign was the battle of Trafalgar, but it must be realised that it was the former that saved England from invasion. In the autumn Napoleon needed a fleet in the Mediterranean and ordered Villeneuve to proceed there. The latter, after a protest, attempted to comply, and was beaten, as all the world knows, on Oct. 21, 1805 with a loss of twenty ships.

The victory of Trafalgar, while it did not end the war, conferred upon England the complete command of the sea. Thereafter naval activity was most pronounced, and the British Navy was employed in numerous undertakings in all parts of the world; but it becomes impossible to trace out any broad policy. It only remains to point out some of the more prominent incidents. Napoleon's operations with Russia produced some naval activity. England attempted to assist that country when in 1807 Napoleon was preparing a final blow against her, by forcing the Dardanelles—Turkey being then allied with France. Admiral Duckworth was selected for the operation, and he actually silenced the batteries in the Straits and appeared off Constantinople. There he was helpless for lack of bombships, and had to retire under a damaging fire. Later in the same year the third coalition against France came to a final end when Napoleon and the Tsar of Russia signed the Treaty of Tilsit, by which they agreed to cease war and both plot for England's overthrow. One scheme they hatched was to seize all the neutral fleets in Europe and employ them against their common enemy. The largest neutral navy was Denmark's, and Canning, having providentially heard of this peculiar arrangement, anticipated a Franco-Russian breach of Danish neutrality by sending Admiral Gambier to "borrow" this fleet for the duration of the war. Gambier bombarded Copenhagen and returned with 70 out of 72 of the Danes' fighting ships.

Napoleon's Berlin and Milan Decrees, by which he hoped to break England's merchant marine, and England's reply with the Orders in Council, also gave the British some opportunities to

show its command of the sea. Napoleon forbade continental countries to import British goods either in British or foreign ships. England in turn seized neutral ships that called at a continental port without also calling at a British port. The struggle forced England to open new markets in the East and in South America, but several countries rebelled against Napoleon's system and England was always ready to help. The revolt of Portugal began in 1808 and produced the Peninsular War which ought to be thought of as partly a naval operation, for the fleet took off the army after Corunna, was always behind Wellington's lines at Torres Vedras, and finally followed, as nearly as possible, his victorious advance. The revolt of Austria in 1809 produced the combined expedition against Antwerp, commanded by Admiral Strachan and Lord Chatham, which hoped to find some sympathy among the Netherlanders for their Austrian ex-rulers. Walcheren and Flushing were captured, but the expedition had to retreat after the collapse of Austria. Finally, England's resistance to Napoleon's decrees involved her in 1812 in war with America who considered herself ill-treated in the matter of the seizure of ships. The British lost many single-ship actions with the Americans—their only success being that of the "Shannon" over the "Chesapeake," but America let her very natural jubilation rather blind her to the fact that her coasts were blockaded without serious challenge.

This is but a small selection from the numerous incidents that make up the naval side of the Napoleonic War after Trafalgar. The main point is that British sea supremacy was unchallenged after that battle, and the British Navy remained Napoleon's worst enemy to the end, for it was the British "Bellerophon" which intercepted him when, after Waterloo, he sought to escape to America to carve out an empire in a new world.

NAPOLEONITE, also called corsite, because the stone is found in Corsica, is a variety of diorite characterized by orbicular structure. The grey matrix of the rock has the normal appearance of a diorite but contains many rounded lumps 1 or 2 in. in diam., which show concentric zones of light and dark colours. In these spheroids also a distinct and well-marked radial arrangement of the crystals is apparent. The centre of the spheroid is usually white or pale grey and consists mainly of feldspar; the same mineral makes the pale zones while the dark ones are rich in hornblende and pyroxene. The feldspar is a basic variety of plagioclase (anorthite or bytownite). Though mostly rounded, the spheroids may be elliptical or subangular; sometimes they are in contact with one another but are usually separated by small areas of massive diorite. When cut and polished the rock makes a beautiful ornamental stone.

Spheroidal structure is found in other diorites and in quite a number of granites in Sweden, Russia, America, Sardinia, Ireland, etc. It is by no means common, however, and usually occurs in only a small part of a granitic or dioritic mass, being sometimes restricted to an area of a few square yards. In most cases it is found near the centre of the outcrop; it arises evidently from intermittent and repeated crystallization of the rock-forming minerals in successive stages, a process which would be favoured by complete rest, allowing of supersaturation of the magma by one of the components. Rapid crystallization would follow, producing deposits on any suitable nuclei, and the crystals then formed might have a radial disposition on the surfaces on which they grew. The magma might then be greatly impoverished in this particular substance, and another deposit of a different kind would follow, producing a zone of different colour. The nucleus

for the spheroidal growth is sometimes an early porphyritic crystal, sometimes an enclosure of gneiss, etc., and often does not differ essentially in composition from the surrounding rock. When spheroids are in contact their inner zones may be distinct, while the outer are common to both individuals, having the outlines of a figure eight. This proves that growth was centrifugal, not centripetal. (J. S. F.)

NAPRAVNIK, EDWARD (1839–1915), Czech conductor and composer, was born at Beisitz in Bohemia on Aug. 26, 1839. He was thrown on his own resources while still young and only obtained his musical education by means of great determination. In 1861 he went to Petersburg (Leningrad) as conductor to Prince Youssipov. Through the influence of Liadov he obtained a post at the Marinsky theatre and in 1869 succeeded him as first conductor there. Under his direction the famous opera-house became the home of Russian opera and ballet, where the works of Glinka, Tchaikovsky, Rimsky-Korsakoff and Glazounov had a permanent place in the repertoire. He died on Nov. 10, 1915. Napravnik wrote several operas, including *Francesca di Rimini*, op. 71; four symphonies and other orchestral works; chamber and piano music; and dramatic choral works.

NAQUET, ALFRED JOSEPH (1834–1916), French chemist and politician, was born at Carpentras (Vaucluse) on Oct. 6, 1834. In 1863 he was made professor of medicine in Paris, and of chemistry in Palermo. In 1867 he was imprisoned for 15 months and lost his professorships for his share in a secret society, and in 1869 took refuge in Spain on the prosecution of his book, *Religion, propriété, famille*. He took part in the revolution of Sept. 4, 1870, and became secretary of the commission of national defence, sitting on the extreme Left in the National Assembly. Re-elected to the Chamber of Deputies he agitated against the marriage laws. By his efforts in the Senate, where he sat from 1883, in 1886 divorce became legal after three years of definite separation, on the demand of one of the parties concerned. In 1890 he resigned from the Senate and took his seat with the Boulangist deputies in the Chamber of Deputies. He wrote *Principes de chimie fondés sur les théories modernes* (1865); *Socialisme collectiviste et socialisme libéral* (1890; Eng. trans., 1891); *Loi du divorce* (1903) and other scientific and political works.

NARA, an important water channel in Sind, India, probably representing a former bed of the Indus, though now traversing the desert far east of the river. It is now a perennial stream 262 m. long, with 631 m. of canals, and irrigates an area of over $\frac{1}{4}$ million acres.

NARA, a town of Japan, in the province of Yamato, 25½ m. from Osaka by rail. Pop. (1925) 54,643. It lies on the slope of a range of picturesque hills, beautifully wooded with cryptomerias and evergreen oaks. Nara remained the metropolis during seven consecutive reigns (709 to 784), and its seventy-five years of favoured existence sufficed for the building and furnishing of several imposing shrines and temples, for the laying out of a noble park and for the casting of a colossal image of Buddha. Not much is known of the Nara palace in its original form, but many of the articles and ornaments used by its inmates survive in a celebrated collection which, during nearly twelve hundred years, had been preserved in a store-house (Shoso-in) near the temple of Todai-ji, which was completed about 750. Worthy of close attention are two effigies of Brahma and Indra preserved among the relics of Koboku-ji, which, with Kasuga-no-Miya, Ni-gwatsudo and Todai-ji, constitute the chief religious edifices. These figures, sculptured in wood, have suffered much from the ravages of time. At the shrine of Kasuga is performed a religious dance called Kagura, in which the costumes and gestures of the dancers are doubtless the same as those of twelve centuries ago. Kasuga-no-Miya was founded in 767, and its chapels with their rough red-painted log-work afford fine examples of primitive Japanese architecture. A railway now gives access to the town, but every effort is made to preserve all the ancient features of Nara.

NARBADA, a river of India. It is traditionally regarded as the boundary between Hindustan proper and the Deccan. It rises on the summit of Amarkantak hill in Rewa state, and for the first 200 m. of its course winds among the Mandla hills, which

form the head of the Satpura range; then at Jubbulpore, passing through the "Marble Rocks," it enters its proper valley between the Vindhyan and Satpura ranges, and pursues a direct westerly course to the Gulf of Cambay. Its total course through the Central Provinces and Gujarat amounts to about 800 m., and it falls into the sea in the Bombay district of Broach. It receives the drainage of the northern slopes of the Satpuras, but not that of the Vindhyan tableland, the streams from which flow into the Ganges and Jumna. After leaving the Central Provinces, the river widens out in the fertile district of Broach, with an average breadth of $\frac{1}{2}$ m. to 1 m. Below Broach city it forms an estuary which is 13 m. broad where it enters the Gulf of Cambay. The Narbada is nowhere utilized for irrigation, and navigation is confined to the lower section. In the rainy season boats of considerable size sail about 60 m. above Broach city. In sanctity the Narbada ranks only second to the Ganges among the rivers of India, and along its whole course are special places of pilgrimage. The most meritorious act that a pilgrim can perform is to walk from the sea to the source of the river and back along the opposite bank.

The Narbada has given its name to a division of the Central Provinces, comprising the five districts of Narsinghpur, Hoshangabad, Nimar, Betul and Chindwara. Area, 18,534 sq.m.; pop. (1921) 2,013,021.

NARBONNE, a city of France, capital of an arrondissement in the department of Aude, in a vine-growing plain 5 m. from the Mediterranean, 37 m. E. of Carcassonne. Pop. (1926) 25,440. Narbonne was the capital of the Volcae Tectosages. There the Romans in 118 B.C. founded their first colony in Gaul, named *Narbo Martius*; they built great works to protect the city from inundation and to improve its port, situated on a lake now filled up. The capital of Gallia Narbonensis, the seat of a proconsul and a station for the Roman fleet, *Narbo Martius* became the rival of Massilia. But the division of Gallia Narbonensis into two provinces lessened its importance. Alans, Suevi, Vandals, each held the city, and at last, in 413, it was occupied by the Visigoths, whose capital it afterwards became. In 719, after a siege of two years, it was captured and extended by the Saracens. Charles Martel, after the battle of Poitiers, and Pippin the Short, in 752, were both repulsed from its walls; but on a new attempt, after an investment of seven years, the Franks again forced their way into Narbonne. Charlemagne made the city the capital of the duchy of Gothia, and divided it into three lordships—one for the bishop, another for a Frankish lord, and the third for the Jews. In the 13th century the archbishopric was seized by the pope's legate, Arnaud Amaury, who took the title of viscount of Narbonne, Simon de Montfort, however, deprived him of this dignity, receiving from Philip Augustus the duchy of Narbonne along with the county of Toulouse. By his expulsion of the Jews Philip the Fair hastened the decay of the city; and about the same period the Aude, which had formerly been diverted by the Romans, ceased to flow towards Narbonne and the harbour was silted up. United to the French crown in 1507, Narbonne was enclosed by a new line of walls under Francis I., but had the last portions of its ramparts demolished in 1870. The archbishopric was founded about the middle of the 3rd century, its first holder being Sergius Paulus; it was suppressed in 1790. The Robine canal, a branch of the Canal du Midi, divides Narbonne into the *bourg* and the *cité*. The former 13th century cathedral (St. Just), consists only of a choir 130 ft. high and transept. The towers (194 ft. high) at each end of the transept date from 1480. The apse of the cathedral was formerly joined to the fortifications of the archiepiscopal palace, and the two buildings are still connected by a mutilated cloister of the 14th and 15th centuries. Part of the palace now serves as *hôtel de ville*, and the palace garden contains many fragments of Roman work; the Musée Lapidaire in the Lamourguier buildings has similar Roman remains. The church of St. Paul, though partly Romanesque, is for the south of France a rare example of a building of the early 13th century in the Gothic style of the north. It possesses some ancient Christian sarcophagi and fine Renaissance wood carving. Narbonne has a sub-prefecture, tribunals of first instance and of commerce, a board of trade arbitrators and a chamber of commerce. It has a good

trade in wine and spirituous liquors, salt, tartar, almonds and leather. The industries include cooperage, sulphur-refining, brandy-distilling and the manufacture of bricks and tiles.

NARBOROUGH, SIR JOHN (d. 1688), English naval commander, was descended from an old Norfolk family. He received his commission in 1664, and in 1666 was promoted lieutenant for gallantry in the action with the Dutch fleet off the Downs in June of that year. After the peace he was chosen to conduct a voyage of exploration in the South Seas. He set sail from Deptford on Nov. 26, 1669, and entered the Straits of Magellan in October 1670 but returned home in June 1671 without accomplishing his original purpose. A narrative of the expedition was published in 1694 under the title *An Account of several late Voyages and Discoveries to the South and North*. During the second Dutch War Narborough was second captain of the lord high-admiral's ship the "Prince," and distinguished himself at Southwold Bay in May 1672. In 1675 he was sent to suppress the Tripoline piracies, and by the bold expedient of despatching gun-boats into the harbour of Tripoli at midnight and burning the ships he induced the bey to agree to a treaty. Shortly after his return he undertook a similar expedition against the Algerines. In 1680 he was appointed commissioner of the navy, an office he held till his death in 1688.

See J. Charnock, *Biographia Navalis*, vol. i. (6 vols., 1794-98).

NARCEINE, one of the alkaloids (*q.v.*) of opium. It belongs to the meconylisoquinoline group and is closely related to narcotine (*q.v.*), being formed, for example, by the action of caustic soda on narcotine methochloride.

NARCISSUS, in Greek mythology, son of the river god Cephissus and the nymph Leiriope, distinguished for his beauty. The seer Teiresias told his mother that he would have a long life, provided he never looked upon his own features. His rejection of the love of the nymph Echo (*q.v.*), or of his lover Ameinias, drew upon him the vengeance of the gods. Having fallen in love with his own reflection in the waters of a spring, he pined away (or killed himself) and the flower that bears his name sprang up on the spot where he died. According to Pausanias, Narcissus, to console himself for the death of a favourite twin sister, his exact counterpart, sat gazing into the spring to recall her features by his own.

It is a very plausible suggestion of Frazer (*Golden Bough*, iii. p. 94) that this story is to be connected with the widespread belief that it is unlucky, or even fatal, to see one's own reflection. This superstition existed in Greece, see Iamblichus, *Protrept.*, 21; Boehm, *de Symbolis Pythagoreis*, p. 51 (1905); Artemidorus, *Oneirocr.* ii., 7 (p. 91, 1, Hercher).

Hence is derived the term *narcissism*, used by psychologists, especially Freudians, for a morbid condition in which the subject is intensely interested in his own body.

BIBLIOGRAPHY.—See Ovid, *Metam.* iii. 341-510; Pausanias ix. 31, 7; Conon, *Narrationes*, 24; F. Wieseler, *Narkissos* (1856); Greve in Roscher's *Lexikon der Mythologie*.

NARCISSUS (d. A.D. 54) was a freedman of Claudius, and his secretary *ab epistulis*. Narcissus and Messallina between them exercised an unbounded influence over the emperor, and arranged the execution or exile of their opponents almost at pleasure. Narcissus was sent to Britain to subdue the mutiny of the soldiers of A. Plautius. He was not well received, but the mutiny subsided. Narcissus was almost solely responsible for the ultimate downfall of Messallina in the Silius affair. It was he who made Claudius alarmed for his own safety, who succeeded in hardening him against Messallina's appeals, and who finally gave the order for her execution when Claudius hesitated. For this he received the insignia of praetor. Eventually he made a false move over Claudius' second marriage, for which he supported Aetia Petina, and further antagonized Agrippina by backing the claims of Britannicus to the throne. As a result he was put to death on Nero's accession in A.D. 54. Narcissus' importance is an early example of the power of the freedmen-secretaries of the emperor's household, and represented the first step towards the transforma-

tion of the emperor's personal staff into an imperial civil service.

See *Sac. Ann.* xi., xii., xiii., i.; *Dio Cass.* ix.; *Suet. Claudius*.

NARCISSUS, a genus of bulbous plants belonging to the family Amaryllidaceae, natives of central Europe, and the Mediterranean region; one species *N. Tazetta*, extends through Asia to Japan. From some of these, by cultivation and hybridization, have arisen the very numerous modern varieties. The plants have long narrow leaves springing from the bulb and a central scape bearing one or more generally large, white or yellow, drooping or inclined flowers. The flowers are regular, with a perianth springing from above the ovary, tubular below, with spreading segments and a central corona; the six stamens are inserted within the tube. The most interesting feature botanically is the "corona" or "cup," which springs from the base of the flower-segments and this gives the special character to the flower.

There are five well-marked sections:

(1) The hoop-petticoat narcissi, sometimes separated as the genus *Corbularia*, are not more than from 3 to 6 in. in height, and have grassy foliage and yellow or white flowers. These have the coronet in the centre of the flower very large in proportion to the other parts, and much expanded, like the old hooped petticoats. They are now all regarded as varieties or forms of the common hoop-petticoat, *N. Bulbocodium*, which has comparatively large bright yellow flowers.

(2) A second group is that of the Pseudonarcissi, constituting the genus *Ajax* of some botanists, of which the daffodil, *N. Pseudonarcissus* is the type. The daffodil is common in woods and thickets in most parts of the north of Europe. Its leaves are about 1 ft. in length and 1 in. in breadth, and have a blunt keel and flat edges. The stem is about 18 in. long and the spathe single-flowered. The flowers are large, yellow, scented and a little drooping, with a corolla deeply cleft into six lobes and a bell-shaped corona which is crisped at the margin; they appear in March or April. In this species the corona is also very large and prominent.

(3) Another group, the mock narcissi or star daffodils, with coronets of medium size, includes the fine and numerous varieties of *N. incomparabilis*, one of which, with large, double flowers, is known as butter-and-eggs; *N. odorus*, known as the campernelle jonquil, has two to four uniform bright yellow flowers, and is considered a hybrid between *N. Jonquilla* and *N. Pseudonarcissus*.

(4) The polyanthus or bunch narcissi form another well-marked group, whose peculiarity of producing many flowers on the stem is indicated by the name. In these the corona is small and shallow as compared with the perianth. *N. Tazetta* is the type of this group. They are general favourites amongst spring flowers. The "Chinese sacred lily" or "joss flower" is a form of *N. Tazetta*. The jonquil, *N. Jonquilla*, with yellow flowers, a native of south Europe and Algeria, is also grown in pots for early flowering, but does well outside in a warm border.

(5) There remains another little group, the poet's or pheasant's-eye narcissi (*N. poeticus*), in which the perianth is large, spreading and conspicuous, and the corona very small and shallow. These pheasant's-eye narcissi, of which there are several well-marked varieties, blossom in succession during April and May, and all do well in the open borders as permanent hardy bulbs.

See F. W. Burbridge, *The Narcissus* (1875); a scientific treatment of the genus will be found in J. G. Baker's *Handbook of Amaryllidaceae* (1888); see also Nicholson, *Dictionary of Gardening* (1886); and J. Weathers, *Practical Guide to Garden Plants* (1901); Sanders, *Encyclopaedia of Gardening* (1912); L. H. Bailey, *The Standard Cyclopaedia of Horticulture* (1915-27).

NARCOTICS, a general term for substances which in healthy animals produce lethargy or stupor, that may pass into unconsciousness with complete paralysis, and end in death. Certain substances of this class are used in medicine for the relief of pain (anodynes), whilst another group produce profound sleep (hypnotics). In one sense, anaesthetics are narcotics, but, as they are usually volatile substances causing unconsciousness for a short time, they are separated from the true narcotics, the effects of which are more lasting. The same substances are sometimes classed as anodynes and at other times as hypnotics. For example, small doses of opium, or of one or other of its preparations, relieve pain, whilst larger doses act as hypnotics, causing deep sleep passing into coma. Cannabis Indica, belladonna and hyoscyamus, are also anodyne in their action. The chief narcotics are dealt with separately (see OPIUM; BHANG; HASHISH; BELLADONNA). Others are:—

Stramonium.—The leaves and seed of the *Datura Stramonium* or thorn apple, the alkaloidal constituent being daturine, a variable mixture of hyoscyne and atropine. The physiological action is almost identical with belladonna. Poisoning is usually due to children eating the seeds; the lethal dose is unknown.

Hyoscyamus, the leaves of the *Hyoscyamus niger* or henbane (*q.v.*). The active principle is hyoscyamine. The physiological action is similar to that of belladonna, but the action of hyoscyamine on the heart is more powerful: $\frac{1}{8}$ gr. of hyoscyamine produces sleepiness and dryness of the mouth; $\frac{1}{2}$ gr. by subcutaneous injection has been fatal. The treatment of hyoscyamus poisoning is similar to that of stramonium.

Hops (*Humulus Lupulus*), containing the active principle lupuline, and *Lactucarium*, the juice of *Lactuca virrosa* (lettuce), containing an alkaloid lactucine, are very feeble narcotics, causing heaviness and sleep if taken in large doses.

Chloral Hydrate is a pure hypnotic which in larger doses is a powerful narcotic, producing prolonged sleep with depression of the cardiac and motor centres. It is an intrinsic cardiac poison, the heart being arrested in diastole, with coincident respiratory failure. Chloral hydrate is not uniform in its action, some people manifesting great susceptibility to the drug. It is safe in small doses of 10 to 20 grs. It is difficult to say what is a lethal dose. Cases are recorded of recovery after 336 grs. taken with an equal amount of potassium bromide and even after a dose of 595 grs., but in susceptible persons 10 to 15 grs. have produced toxic symptoms and death has occurred after doses of from 30 to 45 grs. If seen early, the treatment is an emetic, but if the poison should have been already absorbed, stimulants, hot coffee, strychnine or digitalin hypodermically, with perhaps artificial respiration, may be required.

Alcohol in large quantities is a strong narcotic. The treatment is washing out the stomach to prevent the absorption of the poison and the use of strychnine hypodermically.

NARCOTINE. Though narcotine is a physiologically active opium alkaloid (see ALKALOID) and was at one time used as a remedy for malaria, it is no longer of therapeutical importance except as a source of its derivative cotarnine, the hydrochloride of which is used in medicine as an internal stypic. Narcotine, $C_{20}H_{25}O_4N$, was probably obtained by Derosne in 1803, but was first isolated in a pure state by Robiquet in 1817. It crystallizes from alcohol in long colourless needles, melts at 176° – 198° C in chloroform, and is nearly insoluble in water, sparingly soluble in cold alcohol, but readily so in benzene or ethyl acetate. It also dissolves in weak alkaline solutions and forms unstable salts with acids: the salts are dextro-rotatory, i.e., the rotation is opposite in kind to that of the base. Narcotine is hydrolysed by dilute nitric acid to opianic acid, $C_{16}H_{19}O_5$, and cotarnine, $C_{12}H_{15}O_4N$. The former represents the meconyl residue (see ALKALOIDS) of narcotine, whilst cotarnine represents the isoquinoline portion

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM (NATURAL HISTORY)

NARCISSUS (NARCISSUS TAZETTA)

of the original alkaloid. Cotarnine crystallizes from benzene in small needles, melts at 132°C , is easily soluble in alcohol or ether and sparingly so in cold water. With acids it forms salts, losing a molecule of water at the same time, a circumstance of considerable importance in settling details of the intimate structure of cotarnine. Thus the hydrochloride has the formula $\text{C}_{12}\text{H}_{11}\text{O}_2\text{N}\cdot\text{HCl}\cdot\frac{1}{2}\text{H}_2\text{O}$, melts at 197°C , and crystallizes in pale yellow needles.

NARDINI, PIETRO (1722–1793), Italian violinist and composer, was born at Fribiana in Tuscany in 1722. He studied violin and composition at Leghorn and later became a pupil of Tartini at Padua. For 15 years he held an appointment at the court of Stuttgart as solo violinist. In 1767 he settled at Leghorn and was with Tartini in his last illness. He became music director to the duke of Tuscany in 1770 and enjoyed great fame as a performer and composer. He died at Florence on May 7, 1793. Nardini is remembered as Tartini's most famous pupil, and as the composer of many graceful compositions for the violin. His music is melodious and eminently playable, and has an educational value in respect of technique. Modern reprints of the sonatas are found in Alard's *Maitres classiques*, in David's *Hohe Schule des Violinspiels*, and in Jensen's *Classische Violinmusik*.

NARES, SIR GEORGE STRONG (1831–1915), English Arctic explorer, son of a captain in the navy, was educated at the Royal Naval college at New Cross, and entered the navy in 1846. He served on the Australian station, was mate of the "Resolute" in the Arctic expedition of 1852, and then served in the Crimea. He was then employed in surveying work on the north-east coast of Australia and in the Mediterranean. While in command of the "Challenger" (1872–74), in the famous voyage of deep-sea exploration round the world, he was ordered home to take command of the Arctic expedition which set sail in the spring of 1875 in the ships "Alert" and "Discovery." For his services he was made K.C.B. (1876). Two years later he was sent in command of the "Alert" to survey Magellan strait. He retired from active service in 1886, and became a vice-admiral in 1892. He died at Surbiton, Surrey, on Jan. 15, 1915. (See POLAR REGIONS.)

He published *Reports on ocean soundings and temperature* (1874–75), and *Narrative of a Voyage to the Polar Sea during 1875–76* (1878, 2 vols.).

NAREW, BATTLES OF THE. The battles on the river Narew, north-east of Warsaw, in July and Aug. 1915, were a part of the great offensive planned by Falkenhayn against Russia. During May and June, Mackensen had driven the Russian armies in Galicia from Tarnów on the Dunajec to the east of Lemberg (see DUNAJEC SAN; LEMBERG). In July the group of armies under his command was directed north-east towards Brest-Litovsk against the communications of the Russian forces which still held the Warsaw salient (see BREST-LITOVSK). Hindenburg, who commanded the group of armies on the northern part of the Eastern Front, was now ordered to strike a blow on the north side of the salient. Falkenhayn hoped thus by driving in the flanks of the salient to cut off large numbers of Russians in its apex about Warsaw. The realization of this hope depended, of course, on the rapidity with which the flanks could be forced.

Rival German Plans.—The operation against the Narew line is of interest because of the controversy it provoked between the two men who had most influence on German strategy during the war, Falkenhayn and Ludendorff. The former was at this time chief of the German Great General Staff, and thus responsible for the supreme direction of the war; the latter was chief of staff to Hindenburg. Ludendorff had long cherished the idea of a Napoleonic manoeuvre against the Russian rear by Kovno and Wilno on Minsk, and considered the proposed Narew offensive as timid and ineffectual; Falkenhayn, with heavier responsibilities on his shoulders, mistrusted both the feasibility and the expedience of the Wilno adventure. He could not afford to become so deeply involved in the Eastern theatre as to be unable to withdraw troops to meet the coming offensive in the West. After a discussion of the alternative plans held in the presence of the kaiser, Falkenhayn's views were approved; and Hindenburg was ordered to carry out the Narew attack.

A formidable water barrier protects Russian Poland against invasion from East Prussia, formed by the Niemen, the Bobr, the Narew and the lower course of the Bug, and thence the Vistula to the frontier. The Russians had fortified this river line. Besides the fortresses of Kovno and Grodno, Osoweic, Lomza and Nowa-Georgiewsk, there were fortified bridge-heads on the Narew at Ostroleka, Rozan, Pultusk and Zegrze. Though the river was fordable in the summer at many points, marshes along its length increased its effectiveness as an obstacle.

The German Attack.—Gallwitz's army, which was to make the attack, comprised six corps (14 divisions). Opposite to it, on the lower Vistula, lay the Russian 1. Army (Litvinov) with three corps and a cavalry corps.

The tactical details of the fighting are not of any special interest. On July 13 Gallwitz delivered his first attack on the approximate line Przasnysz-Ciechanów, aiming at Pultusk. The Russians, over-weighted both in numbers and heavy artillery, at once fell back more than half-way to the Narew line. They were attacked again on July 15, and during July 18 and 19 withdrew across the river, the Russian XII. Army on their right conforming to the movement. Reinforcements had now arrived and resistance stiffened. Though the Germans stormed the bridge-heads of Pultusk and Rozan on July 23, and secured crossings over the river, their further progress was limited by violent Russian counter-attacks, and they were unable to reach the line Wyszów-Ostrów (on the lower Bug), at which they were aiming. An attempt to force a passage further east at Ostroleka on July 30 failed, and it was not until Aug. 4 that this bridge-head fell. Losses were heavy on both sides; but the Russians had secured time and space sufficient to evacuate the Warsaw salient without danger.

Hindenburg and Ludendorff naturally claimed that the result of the battle vindicated their opinion on the mistaken strategy of the Supreme Command. Falkenhayn retorted that the operations would have had the desired effect of intercepting the Russian retreat had Hindenburg used the full force available and given Gallwitz 20 divisions instead of 14. It seems doubtful, however, whether the communications would have allowed the effective employment of so large a force.

NARNI (anc. Umbrian *Nequinum*, Rom. *Narnia*), a town and episcopal see of the province of Perugia, Italy, 65 m. N. of Rome by rail. Pop. (1921) 5,544 (town), 14,014 (commune). It is picturesquely situated on a lofty rock (787 ft.). The cathedral and the portico of S. Maria Impensole are Romanesque; the former has some good Renaissance sculptures. There are other interesting churches and some picturesque Gothic houses and palaces. There are factories of linoleum and calcium carbide.

The Umbrian Nequinum was taken by the Romans in 299 B.C., and a colony planted there against the Umbrians. It was situated on the Via Flaminia, and one of the finest bridges of antiquity crosses the river below the town. The original main road ran to Nuceria by Mevania; a branch by Interamna and Spolegium joined it at Forum Flaminii. According to some authors, the emperor Nerva was born at Narnia. The town played a considerable part in military history. In the middle ages Narni was under the papal power. It was the birthplace of the well-known condottiere Erasmo Gattamelata (d. 1443), whose statue by Donatello is at Padua.

See G. Erolì, *Miscellanea Storica Narnese* (2 vols., Narni, 1858–1862), and other works by the same author.

NAROCZ, BATTLE OF LAKE. Lake Narocz, in Lithuania, 62m. E.N.E. of Wilno (Vilna), gives its name to a great offensive by the Russian 2nd Army in the spring of 1916. (See WORLD WAR: Section viii. and MAP.)

General Situation on the Eastern Front.—The river Pripet formed the dividing line between the German and Austrian commands. At the beginning of March there were 42 German and

two Austrian divisions on the front north of the Pripet, the total length of which was about 250 miles. The Russians had organized their armies into three groups: the northern (12th and 5th Armies) on the Dvina, the western (1st, 2nd, 10th, 4th and 3rd Armies) extending to south of the Pinsk marshes and the south-western (8th, 11th, 7th and 9th Armies) up to the Rumanian border. Their main strength was concentrated on the northern and western fronts, where it had been decided that the principal efforts of the year should be made. The losses of 1915 in men and material had been made good; guns and munition were available on a larger scale than previously, though still insufficient for the requirements of trench warfare.

Plan of Operations.—The general idea of the battle was for the 2nd Army to attack on either side of Lake Narocz, where the German line formed a slight salient; the two wings were eventually to join and to continue their advance westwards to Panevžys (some 80m. N. of Wilno [Vilna] and 100m. W. of the original line), where the 5th Army, which was to attack from the Jakobstadt bridgehead on the Dvina, was to join them. The operation seems to have been planned originally to take place later in the year, when all the Allies proposed to attack simultaneously. But on Feb. 21 the German assaults on Verdun began, and the Russians chivalrously hurried on their preparations and attacked to relieve the pressure on the French, at the worst possible time of the year—when the annual thaw, which renders all communications practically impossible for a period, might be expected at any moment.

Description of the Terrain.—Lake Narocz (8m. by 6m.) is the largest of a whole series of small lakes in which the tributaries of the Wilia and the Dzisna rise. It drains into the River Narocz, which flows south to join the Wilia east of Smorgonie. The greater part of the trench line between Dvinsk and Smorgonie (over 100m. in a straight line) was protected by lake, stream or marsh, and stretches of dry ground wide enough for a large scale offensive were few. On either side of Lake Narocz, however, were gaps of four miles or so in the water line, where the terrain was comparatively favourable for attack, though communications were poor. The northern gap was ten miles to the north of Lake Narocz; the southern was between the lake itself and Lake Wiszniew.

Dispositions of the Opposing Forces.—The 2nd Army was divided into three groups: the right group (under Gen. Plyeshkov), opposite the northern gap, consisted of three corps and a cavalry corps; the centre group (under Gen. Sirelius), of two corps; and the left group (under Gen. Baluev), of three corps. Four corps were available behind these groups to exploit any success gained. The right and left groups were to attack the north and south faces of the salient respectively, while the centre group assisted by minor assaults and demonstrations. The army commander, Smirnov, fell sick just before the battle and his place was taken by Gen. Ragoza.

The 2nd Army was opposed by Von Eichorn's 10th Army on a front of some 85 miles, comprising 11 divisions and two cavalry divisions. The Germans were aware of the Russian concentration.

The Russian Attacks.—A thaw set in on March 17, but the offensive was nevertheless begun on the 18th. After a bombardment of several hours, massed infantry attacks were made both by Plyeshkov's group north of Lake Narocz and by Baluev's group in the south. In the thickly wooded and enclosed terrain the in-

sufficiently trained Russian infantry soon lost cohesion, and their assaults were ill-timed and disjointed. Though the German first-line trenches were in several cases occupied, they could not be held under the concentrated fire of the German artillery, which was extremely skilfully handled. By nightfall the Russians were back in their original positions, having suffered very heavy casualties without result. After two days of further artillery preparation and minor attacks intended to mislead the enemy, renewed heavy assaults were made on the nights of March 19–20 and 20–21.

On Plyeshkov's front no ground was permanently gained in spite of terrible losses, but Baluev's group in the south made an advance of over a mile on a front of about 2½ miles. The weather conditions were by now terrible; it thawed from the 17th to the 22nd, and the whole area of operations became a sea of mud. The battle was, however, continued till March 27, when the Russians at last desisted from their fruitless and costly attacks. In April a German counterstroke retook all the ground gained by Baluev. Meanwhile the attacks of the 5th Army from Jakobstadt, March 21–26, were equally unsuccessful and almost equally wasteful of life.

Results of the Operations.—The operations resulted in a complete and disastrous failure for the Russians. Their losses were over 100,000 and they accomplished nothing. The offensive did not cause the Germans to move a single man from the Western Front, and so brought no relief to the French. Both time and place were ill-chosen; the staff work was bad; and the artillery, in spite of a greater concentration of heavy guns on a narrow front and a more liberal expenditure of ammunition than ever before, failed to give proper support to the infantry, who, as usual, paid the price in terrible losses. The result was, in fact, a bitter disillusionment to the Russian high command, to the Russian soldier and to the Russian people.

NARRA or **ASANÁ**, the local names (Philippine dialect) applied to some of the best timber trees, *Pterocarpus indicus*, *P. echinatus* and *P. blancoi* (family Leguminosae) in the Philippine archipelago. The wood is commonly known as "Philippine mahogany," and is in great demand for cabinet-work; it is usually of a beautiful red or rose colour, often variegated with yellow, and is hard and heavy. The trunk is surrounded (or, occasionally, supported) by huge buttresses extending outward and upward for 10 to 20 ft.; these are sometimes made into table-tops, the pattern of the grain and the colouring being hardly equalled by any other timber. The wood-cells contain a peculiar substance: a minute chip placed in a bottle of water soon gives an opalescent colour to the liquid. Narra is known as Burmese rosewood, Andaman redwood and Kiabooca-wood.

NARRAGANSETT PIER, a summer resort of Washington county, Rhode Island, U.S.A., on the west shore of Narragansett bay, 25 m. S. of Providence. It is on Federal highway 1, and is served by the Narragansett Pier railroad, connecting at Kingston (9 m. N.W.) with the New York, New Haven and Hartford. The town of Narragansett, in which it is situated, had a resident population of 1,357 in 1925 (State census). "The Pier" consists of a group of hotels, a casino and a bathing pavilion, on a crescent-shaped beach (one of the finest on the Atlantic coast), and an avenue (lined on both sides with palatial summer "cottages") running down the rocky promontory to Point Judith (5 m. S.), where there is a lighthouse and a country club. Narragansett Pier was so named from the wharves built late in the 18th century to provide a port for southern Rhode Island, but none of them are left. Development as a summer resort began about the middle of the 19th century, and the railroad from Kingston was completed in 1876. It has always had a considerable number of visitors from the South.

NARSES (c. 478–573), an important officer of Justinian, in the 6th century. He was a eunuch of Persamenia, and apparently born about 478. If the statement that he died at the age of ninety-five be correct, he was probably brought young to Constantinople,

PLAN OF THE BATTLE OF LAKE NAROCZ, MARCH 18, 1916

and attained a footing in the *officium* of the grand chamberlain. He rose to be one of the three "chartularii," a position involving the custody of the archives of the household. Hence, probably in middle life, he became "praepositus sacri cubiculi."

In 532 the insurrection known as the Nika broke out in Constantinople, when for some hours the throne of Justinian seemed doomed to overthrow. It was saved partly by the courage of his wife, Theodora, and partly by the timely prodigality of Narses, who stole out into the capital, and with large sums of money bribed the leaders of the "blue" faction, which was aforesaid loyal to the emperor, to shout as of old "Justiniane Auguste tu vincas." He defeated Totila in 552, with whom fell the last hopes of the Gothic kingdom of Italy.

NARSINGHGARH, an Indian state in the Bhopal agency of Central India. Area 734 sq.m.; pop. (1921) 101,426. The chief, whose title is raja, is a Rajput of the Umat clan. The state was founded about 1681 by a minister of Rajgarh, who compelled the ruler of that state to transfer to him half his territory. The town of Narsingharh had a population in 1921 of 8,762.

NARTHEX, in architecture, a long, narrow porch, usually colonnaded or arcaded, at the entrance of a church. In the early days of Christianity it was the only portion of the church to which catechumens and penitents were admitted. Occasionally an additional vestibule exists within the church building proper. In this case, the inner vestibule is called the narthex and the outer porch an exonarthex. The narthex is common in basilican, Byzantine and some Romanesque churches, particularly in Italy; in the Gothic period its use had almost entirely disappeared, but during the Renaissance it is again found, although its ritual usage had entirely died out, and it had become a simple porch or vestibule.

NARVA, a seaport of Estonia in 59° 23' N., 28° 12' E., on the Narova river, 8 m. above its entry into Narva Bay on the Gulf of Finland. Pop. (1926) 27,000. With it is associated Narva-Joensuu (Hungerburg) in 59° 28' N., 28° 3' E. Pop. 3,000. Vessels loading wood lie at anchor in the latter and load from lighters, while steamers of 15½ to 16 ft. draught can load in its harbour. The chief imports are cotton, rye, salt, herrings and coal and the exports textiles, timber (pit-props, battens, etc.), spirits and bricks. The textile mills at Narva utilizing the waterfalls on the river escaped the general destruction following 1914, partly because until the 1917 revolution the mills were executing orders for the Russian Ministry of War. The cotton mills were closed for two years but are working now, though only 2,000 workers are employed as against 11,000 in 1914. The woollen, flax and jute mills are similarly reduced. Russia was previously the chief market, but has now dropped out and in view of Estonia's development as a dairy producing country, the textile industry may not revive. Founded by the Danes in 1223, the town changed hands between the Teutonic Knights, Danes, Swedes and Russians until its capture by Peter the Great in 1704, after which it remained under Russian rule until Estonia obtained independence in 1918-1920.

NARVACAN, a municipality (with administration centre and 28 *barrios* or districts) of the province of Ilocos Sur, Luzon, Philippine Islands, near the coast and on the main road 13 m. S.S.E. of Vigan, the provincial capital. Pop. (1918) 23,071. It lies in a level valley surrounded by mountains and the climate is cool and healthy. The soil in the vicinity is fertile, and produces rice, corn, cotton, tobacco, maguay and sugar. Cotton is woven by the women and sold to the mountain peoples. In 1918, Narvacan had 92 household industry establishments, with outputs valued at 32,400 pesos. The 15 schools were all public. The language spoken is Ilocano.

NARVAEZ, PÁNFILO DE (c. 1480-1528), Spanish adventurer, born at Valladolid. He helped Velasquez in the reduction of Cuba and was put at the head of the force sent to the Aztec coast to compel Cortes to renounce his command. He was defeated by his compatriot and made prisoner (1520). On his return to Spain he obtained from Charles V. a grant of Florida as far as the river of Palms: landing near Pensacola bay in April 1528, he struck inland with some 300 of his followers and reached

"Apalache" on June 25. Disillusioned in their hopes of fabulous wealth, they made for the coast, arriving in July at the Bahia de los Caballos, at or near St. Mark's. Having built rude boats, the much-reduced company sailed on Sept. 22, for Mexico, but the vessel which carried Narvaez perished in the storm. His lieutenant, Cabeza de Vaca, and three others ultimately reached the Gulf of California by way of Texas. (See FLORIDA.)

See W. H. Prescott, *Conquest of Mexico*; H. H. Bancroft, *Mexico* (1882-90); *Naufragio de Alvaro Nunez Cabeza de Vaca* (Bib. de Autores Esp., xxii.).

NARVAEZ, RAMÓN MARÍA (1800-1868), Spanish soldier and statesman, born at Loja, Granada on Aug. 4, 1800. He served under Mina in Catalonia in 1822. As one of the Conservative supporters of Isabella II. he achieved great popularity by his victory over Gomez, the Carlist general, near Arcos, in Nov. 1836, and after clearing La Mancha of brigands in 1838 he was appointed captain-general of Old Castile, and commander-in-chief of the army of reserve. After taking part in the Seville insurrection (1840) against Espartero and the Progresista party, he fled to France and planned with Maria Cristina the expedition of 1843, which led to the overthrow of his adversary. Prime minister, field-marshal, and duke of Valencia in 1844, his reactionary policy culminated in his having to quit office in Feb. 1846. He became ambassador at Paris, returned in 1847 to preside over the council of ministers and resigned in 1848 through misunderstandings with Maria Cristina. His ministry succeeded that of O'Donnell in 1856-57, 1864-65 and in July 1866. He died at Madrid April 23, 1868.

NARVIK or **VICTORIAHAVN**, an ice-free seaport on the Ofoten Fjord of the north-west coast of Norway, in Nordland amt (county), 68° 30' N. Pop. (1927) 7,150. It is wholly modern, developed by the construction and completion (1903) of the Lapland railway, the most northerly in the world. There are extensive quays, from which is shipped the iron ore from Kiruna and other Swedish mining districts traversed by the line. Narvik is 167 m. N.W. of Gellivara, and 982 N. by W. of Stockholm by the railway.

NARWHAL, a cetacean (*Monodon monoceros*), characterized by the presence in the male of a long horn-like tusk. In the adult of both sexes there are only two teeth, both in the upper jaw, which lie horizontally side by side, and in the female remain throughout life concealed in cavities of the bone. In the male the right tooth usually remains similarly concealed, but the left is immensely developed, attaining a length equal to nearly that of the entire animal. It projects forwards from the head in the form of a cylindrical or slightly tapering, pointed tusk, composed of ivory, with a central cavity reaching almost to the apex, without enamel, and with the surface marked by grooves and ridges running in a left-handed spiral. Occasionally both left and right tusks are developed. In young animals several small additional teeth are present, but these generally disappear soon after birth.

The head is short and rounded; the fore limbs or paddles are small and broad, and (as in the Beluga) a dorsal fin is wanting. The general colour is dark grey variously marbled and spotted with grey.

The narwhal is an Arctic whale rarely seen south of 65° N. lat. Like most cetaceans it is gregarious and usually met with in "schools" of 15 or 20 individuals. Its food appears to be cuttlefishes, small fishes and crustaceans. The purpose served by the tusk is uncertain. The narwhal is extremely playful, individuals frequently elevating their tusks and crossing them with each other as in fencing. They have never been known to charge and pierce the bottom of ships with their weapons as the swordfish does. The ivory of the tusk is of good quality, but owing to the central cavity, only fitted for the manufacture of objects of small size. The entire tusks are sometimes used for decorative purposes. (See CETACEA.)

NASCIMENTO, FRANCISCO MANOEL DE (1734-1819), Portuguese poet, known as Filinto Elysio, his "Arcadian" name, though he was never a member of the Arcadia and later was a leader of the revolt against it, was born in Lisbon, the son of a lighterman. As a boy he acquired an extensive knowledge

of national literature and folklore, the foundation of his rich Portuguese vocabulary and of a deep and enduring patriotism. He was ordained priest in 1754, and became treasurer of the Chagas church in Lisbon. Nascimento was soon the centre of a literary group which opposed the ruling group of the Arcadia, and fought for the recognition of Camoens as the greatest of Portuguese poets. But in June 1778 an order was issued by the inquisition for the arrest of Nascimento on the ground of heterodoxy and the reading of "modern philosophers who follow natural reason." He escaped to a French ship in the harbour, found his way to Havre and then to Paris, where he spent the rest of his life, with the exception of five years in the house of the Portuguese ambassador at The Hague. Lamartine addressed an ode to him; he enjoyed the esteem of Chateaubriand; and his admirers at home, who imitated him extensively, were called after him *Os Filintistas*. Exile and suffering had enlarged his ideas and given him a sense of reality, making his best poems those he wrote between the ages of 70 and 85, and when he died it was recognized that Portugal had lost her foremost contemporary poet.

Garrett declared that Nascimento was worth an academy in himself by his knowledge of the language, adding that no poet since Camoens had rendered it such valuable services; but his truest title to fame is that he brought literature once more into touch with the life of the nation. By his life, as by his works, Nascimento links the 18th and 19th centuries, the Neo-Classical period with Romanticism. Wieland's *Oberon* and Chateaubriand's *Martyrs* opened a new world to him, and his *contos* or scenes of Portuguese life have a real romantic flavour; they are the most natural of his compositions, though his noble patriotic odes—those "To Neptune speaking to the Portuguese" and "To the liberty and independence of the United States"—are the most quoted and admired. On leaving Portugal, he abandoned the use of rhyme as cramping freedom of thought and expression; nevertheless, his highly-polished verses are generally robust to hardness and overdone with archaisms.

BIBLIOGRAPHY.—The most useful edition of his collected works is that in 22 vols., 1830-40. See Innocencio da Silva, *Dicionario bibliographico Portuguez*, ii. 446-457 and ix. 332-336; also Pereira da Silva, *Filinto Elysio e a sua Epoca* (Rio, 1891); and Dr. Theophilo Braga, *Filinto Elysio* (Oporto, 1891).

NASEBY, a village of Northamptonshire, England, 7m. S.S.W. of Market Harborough, famous as the scene of the battle of June 14, 1645, which decided the issue of the first Civil War (see GREAT REBELLION). The army of King Charles I. was less than 10,000 strong, while the "New Model" army of the parliament, commanded by Sir Thomas Fairfax, numbered some 13,000. Yet it was not without considerable hopes of victory that the Royalists drew up for battle, for although Lieutenant-General Cromwell had made the New Model cavalry formidable indeed, the Royalist foot had become professionalized in several years of war, whereas the Parliamentary foot was newly organized, and in part at least but half-trained. Fairfax and Cromwell, however, were still more confident, and with better reason. The battlefield lies between Naseby and Sibbertoft (3m. N. of Naseby) and is an undulating ridge which, near the centre of England, forms the "divide" between the Avon and the Welland rivers. Across this ridge the two armies were drawn up, the New Model facing north and the king's army south, the horse on the flanks and the foot in the centre of each army.

At the first shock the Royal foot asserted its superiority over the opposing infantry, four out of five regiments in the first line were broken, and Skippon, the major-general of the foot, was wounded. But Fairfax's regiment held its ground, until the second line of infantry advanced and re-established the front. Meantime the Royalist right wing of horse, led by Prince Rupert, had completely routed the horse of Colonel Ireton which opposed them. But the victors as usual indulged in a disorderly pursuit, and attempted to overpower the baggage guard of the enemy near Naseby village. Their incoherent attack was repulsed, and when Rupert, gathering as many of his men as he could, returned to the battlefield, the decisive stroke had been delivered by Cromwell and the right wing of Parliamentary horse. In front of him, in some-

what broken ground, was Sir Marmaduke Langdale's cavalry, which the lieutenant-general with his own well-trained regiments scattered after a short, fierce encounter. Cromwell's "godly" troopers did not scatter in pursuit. A few squadrons were ordered to keep the fugitives on the run, and with the rest, and such of Ireton's broken troops as he could gather, Cromwell attacked the Royalist centre in rear while Fairfax and his foot pressed it in front. Gradually the Royalist infantry, inferior in numbers, was disintegrated into small groups, which surrendered one after the other. But one brigade, called the "Bluecoats," held out to the last, and was finally broken by a combined charge of Fairfax's regiment of foot, led by Cromwell, and the general's personal escort, led by Fairfax himself, who captured a colour with his own hand. The remnant of the king's army, re-formed by Rupert, stood inactive and irresolute while its infantry was being destroyed and then fled. The spoils included 100 standards and colours and the king's private papers. But more important than trophies was the practical annihilation of the last field army of which the king disposed. Half the Royalists were captured, and about 1,000 fell in the battle and the pursuit which followed it. In addition all the artillery and the muskets (to the number of 8,000) and ammunition without which the king could scarcely create a new army, fell into the hands of the victors.

NASH, PAUL (1889-), British painter, was born in London on May 11, 1889, and educated at St. Paul's School and at the Slade School. His first exhibition was given in 1911, but he was comparatively little known until an exhibition of his western front war pictures (1918), the fruit of his work as an official artist 1917-18; several of these are in the Imperial War Museum, London. He then attracted attention as a landscape painter of individuality and charm, a somewhat mannered technique giving way gradually to a freer expression; he gave an important exhibition in London in 1924. He also produced some interesting woodcuts and book illustrations, such as the wood engravings, "Genesis" (1924). He was instructor of design at the Royal College of Art, South Kensington.

NASH, RICHARD (1674-1762), English dandy, better known as "Beau Nash," was born at Swansea on Oct. 18, 1674. He was educated at Carmarthen grammar school and at Jesus college, Oxford. He obtained a commission in the army, which however, he soon exchanged for the study of law at the Temple. Here among "wits and men of pleasure" he came to be accepted as an authority in regard to dress, manners and style. When the members of the Inns of Court entertained William III. after his accession, Nash conducted the pageant at the Middle Temple. He was offered knighthood, but he declined the honour, unless accompanied by a pension. The pension was not given and Nash turned gamester. In 1705 he succeeded Captain Webster as master of the ceremonies at Bath. Under his régime Bath became the leading fashionable watering-place. He drew up a new code of rules for the regulation of balls and assemblies, abolished the habit of wearing swords in places of public amusement and brought duelling into disrepute, induced gentlemen to adopt shoes and stockings in parades and assemblies instead of boots, reduced refractory chairmen to submission and civility, and introduced a tariff for lodgings. Through his exertions a handsome assembly-room was also erected, and the streets and public buildings were greatly improved. Nash adopted an outward state corresponding to his nominal dignity. He wore an immense white hat as a sign of office, and a dress adorned with rich embroidery, and drove in a chariot with six greys, laced lackeys and French horns. When the act of parliament against gambling was passed in 1745, he was deprived of an easy though uncertain means of subsistence, but the corporation afterwards granted him a pension of six score guineas a year, which, with the sale of his snuff-boxes and other trinkets, enabled him to support a certain faded splendour till his death on Feb. 3, 1762. He was honoured with a public funeral at the expense of the town. He was a man of strong personality, and considerably more able than Beau Brummel, whose prototype he was.

See Oliver Goldsmith, *Life of Richard Nash* (1762); Lewis Melville, *Bath under Beau Nash* (1908), with full list of authorities.

NASHE (or **NASH**), **THOMAS** (1567-1601), English poet, playwright and pamphleteer, was born at Lowestoft in 1567. His father belonged to a Herefordshire family, and is vaguely described as a "minister." Nashe spent 6 years, 1582-1588, at St. John's College, Cambridge, taking his B.A. degree in 1586. On leaving the university he tried, like Greene and Marlowe, to make his living in London by literature. It is probable that his first effort was *The Anatomie of Absurditie* (1588) which was perhaps written at Cambridge, although he refers to it as a forthcoming publication in his preface to Greene's *Menaphon* (1589). In this preface, addressed to the gentlemen students of both universities, he makes boisterous ridicule of the bombast of Thomas Kyd and the English hexameters of Richard Stanihurst, but does not forget the praise of many good books. Nashe was really a journalist born out of due time; he boasts of writing "as fast as his hand could trot"; he had a brilliant and picturesque style which, he was careful to explain, was entirely original; and in addition to his keen sense of the ridiculous he had an abundance of miscellaneous learning.

As there was no market for his gifts he fared no better than the other university wits who were trying to live by letters. But he found an opening for his ready wit and keen sarcasm in the famous Martin Marprelate controversy. His share in this war of pamphlets cannot now be accurately determined, but he has been credited, on doubtful evidence, with the following: *A Counter-cuffe given to Martin Junior* (1589), *Martins Months Minde* (1589), *The Returne of the renowned Cavaliero Pasquill and his Meeting with Marjorius* (1589), *The First Parte of Pasquills Apologie* (1590), and *An Almond for a Purrat* (1590). He edited an unauthorized edition of Sidney's poems in 1591, and *A Wonderful Astrologically Prognostication*, in ridicule of the almanac-makers, by "Adam Foulweather," which appeared in the same year, has been attributed to him. *Pierce Penilesse, His Supplication to the Divell*, published in 1592, shows us his power as a humorous critic of national manners, and tells incidentally how hard he found it to live by the pen. It seems to Pierce a monstrous thing that brainless drudges wax fat while "the seven liberal sciences and a good leg will scarce get a scholar bread and cheese."

In this pamphlet, too, Nashe began his attacks upon the Harveys by assailing Richard, who had written contemptuously of his preface to Greene's *Menaphon*. Greene died in September 1592, and Richard's brother, Gabriel Harvey, at once attacked his memory in his *Four Letters*, at the same time adversely criticizing *Pierce Penilesse*. Nashe replied, both for Greene and for himself, in *Strange Newes of the intercepting certaine Letters*, better known, from the running title, as *Four Letters Confuted* (1592), in which all the Harveys are violently attacked. The autumn of 1592 Nashe seems to have spent at or near Croydon, where he wrote his satirical masque of *Summers Last Will and Testament* at a safe distance from London and the plague. He afterwards lived for some months in the Isle of Wight under the patronage of Sir George Carey, the governor. In 1593 he wrote *Christs Teares over Jerusalem*, in the first edition of which he made friendly overtures to Gabriel Harvey. These were, however, in a second edition, published in the following year, replaced by a new attack, and two years later appeared the most violent of his tracts against Harvey, *Have with you to Saffron-walden, or, Gabriell Harveys Hunt is up* (1596). In 1599 the controversy was suppressed by the archbishop of Canterbury.

After Marlowe's death Nashe prepared his friend's unfinished tragedy of *Dido* (1596) for the stage. In the next year he was in trouble for a play, now lost, called *The Isle of Dogs*, for only part of which, however, he seems to have been responsible. The "seditious and slanderous matter" contained in this play induced the authorities to close for a time the theatre at which it had been performed, and Ben Jonson (*q.v.*) and others were imprisoned. Apparently Nashe escaped. Besides his pamphlets and his play-writing, Nashe turned his energies to novel-writing. He may be regarded as the pioneer in the English novel of adventure. He published in 1594 *The Unfortunate Traveller, Or the Life of Jack Wilton*, the history of an ingenious page who was present at

the siege of T  rouenne, and afterwards travelled in Italy with the earl of Surrey. It tells the story of the earl and Fair Geraldine, describes a tournament held by Surrey at Florence, and relates the adventures of Wilton and his mistress Diamante at Rome after the earl's return to England. The detailed, realistic manner in which Nashe relates his improbable fiction resembles that of Defoe.

His last work is entitled *Lenten Stufte* (1599) and is nominally "in praise of the red herring," but really a description of Yarmouth, to which place he had retired after the trouble over *The Isle of Dogs*. Nashe's death is referred to in Thomas Dekker's *Knight's Conjuring* (1607), a kind of sequel to *Pierce Penilesse*. He is there represented as joining his boon companions in the Elysian fields "still haunted with the sharp and satirical spirit that followed him here upon earth." Had his patrons understood their duty, he would not, he said, have shortened his days by keeping company with pickled herrings. The date of his death is fixed by an elegy on him printed in Fitzgeffrey's *Affaniac* (1601).

The works of Thomas Nashe were edited by Dr. A. B. Grosart in 1883-85, and by Ronald B. McKerrow (1904-1910). See also *English Novel in the Time of Shakespeare*, by J. J. Jusserand (Eng. trans., 1890); and F. G. Harman, *Gabriel Harvey and Thomas Nashe* (Ouseley, 1923).

NASHUA, a city of southern New Hampshire, U.S.A., on the Merrimack river at the mouth of the Nashua, 15 m. S. of Manchester and 40 m. N.W. of Boston; one of the county seats of Hillsboro county. It is on Federal highway 3, and is served by several divisions of the Boston and Maine railroad. Pop. (1920) 28,379 (31% foreign-born white, including 4,385 French-Canadians and 1,067 Greeks). Nashua is beautifully situated in an amphitheatre of hills and mountains. There is abundant water-power, and the city has extensive manufactures (notably of cotton goods, paper, asbestos shingles and refrigerators) with an output in 1925 valued at \$44,541,707. A U.S. fish hatchery is near by. A settlement known as Indian Head was established here in 1665. In 1803 it was incorporated as the village of Nashua, and in 1836 the town of Dunstable (in which it was situated) took the same name. The town of Nashville was set off from the town of Nashua in 1842, but the two were reunited in 1853 under a city charter.

NASHVILLE, the capital city of Tennessee, U.S.A., a port of entry, and the county seat of Davidson county; on the Cumberland river in the north-central part of the State. It is on Federal highways 31, 41 and 70; has a municipal airport; and is served by the Louisville and Nashville, the Nashville, Chattanooga and St. Louis and the Tennessee Central railways, motor-bus lines and river packets. Pop. 118,342 in 1920 (30% negroes and 98% native-born); estimated locally at 147,000 in 1928, with an additional 30,000 in the adjacent suburbs. The city covers 21½ sq.m., on hills and bluffs averaging 500 ft. above sea-level, in a vast undulating elliptical valley of 5,450 square miles. The surrounding country is a blue-grass region of great fertility. Within 25 m. of the city practically everything is raised that is needed for food and clothing, and most of the necessities of life are manufactured. Seven bridges cross the river. On the highest hill stands the State House, a fine example of pure Greek architecture, with a cupola 205 ft. high. The tomb of President Polk is in the capital grounds, and 11 m. east of the city is "The Hermitage," the beautiful plantation home of President Jackson. In Centennial park, where the Tennessee Centennial Exposition was held in 1897, is a copy of the Parthenon. Mt. Olivet cemetery contains a beautiful monument to the Confederate soldiers, surrounded by 2,000 of their graves, and north of the city is a National cemetery where 16,862 Federal soldiers are buried. A memorial to the soldiers and sailors of the World War (covering two blocks and containing a large auditorium) was erected by the city, the county and the State, at a cost of \$2,600,000. The Tennessee State fair is held at Nashville annually, and many of the State institutions are situated here, including the Confederate Soldiers' Home, the Industrial school, the school for the blind, the Middle Tennessee hospital for the insane, the penitentiary, and the Training and Agricultural school for boys. The public parks cover 2,100 ac.; the hotels have 1,500 guest-rooms; there are 257 churches, includ-

ing a Roman Catholic cathedral, 36 public schools and 40 under private auspices. The city's assessed valuation for 1928 was \$169,623,822. Since 1913 it has operated under a commission form of government.

Nashville is one of the foremost educational centres in the South. Vanderbilt university (founded in 1873 by Commodore Vanderbilt, who contributed \$1,000,000 towards its funds, and whose son and grandsons have given over \$2,000,000) has grounds and buildings valued at \$5,652,724, productive funds of \$10,000,000 and an enrolment (1927-28) of 1,401. Its medical school has been housed since 1925 in a well equipped and comprehensive plant, built with grants from the General Education Board and the Carnegie Corporation and earlier gifts from Andrew Carnegie. The George Peabody college for Teachers (opened as a normal school in 1875) has an endowment of \$4,133,000 and an enrolment (1928) of 3,858. Fisk university (for negroes), founded in 1865 by the American Missionary Association and the Western Freedmen's Aid Commission, has buildings and grounds valued at \$500,000, endowment funds of nearly \$300,000, and an annual enrolment of about 700. The Fisk Jubilee Singers, sent out first in 1871 to raise money for a dormitory for women, have sung in most of the large cities of America and Europe. Nashville is the seat also of the Agricultural and Industrial State college and the Meharry Medical college (both for negroes).

Among the most important manufacturing industries are printing and publishing (especially of religious periodicals and books), coffee-roasting, and the manufacture of stoves and furnaces, hardwood flooring, fertilizers, cloth and paper bags, boots and shoes, self-raising flour, furniture, knit goods, building materials, wooden and paper boxes, work garments, shirts, soft collars, women's dresses and underwear, brick, mattresses, tobacco and snuff, steel barges, feather pillows, chewing gum and clinical thermometers. Two of the railroads have shops here, employing together over 3,000 persons. The factory output in 1928 was valued at \$100,000,000. Nashville is the seat of a branch of the Federal Reserve Bank. Bank debits in 1927 aggregated \$1,090,140,000.

History.—In Nov. 1779, James Robertson and eight companions, who had set out in February from the Watauga settlements in eastern Tennessee to establish an "advance guard of civilization" in the rich central basin, arrived at the spot where Nashville now stands, and decided to make it the site of the new settlement. They were joined a few months later by their wives and children and other pioneers, under Col. John Donelson. The town (called Nashborough until its incorporation in 1784) was named after either Abner Nash, then governor of North Carolina, or his brother Francis, a Revolutionary general, killed at Germantown. In 1806 it was chartered as a city. From 1812 (except from 1815 to 1826) the legislature met at Nashville, and in 1843 it was made the State capital. On June 3, 1850, it was the scene of the Southern, or Nashville, Convention, attended by 100 delegates from nine States, which denounced the Wilmot Proviso and (at an adjourned meeting in November) expressed disapproval of the Compromise Measures and asserted the right of the South to secede. For the battle of Nashville (1864) see below. During the World War the Government established the Old Hickory Powder plant in the wilderness across the river, constructing large factory buildings and a village to accommodate 30,000 persons. (X.)

BATTLE OF NASHVILLE

During the Civil War Nashville was captured by the Federals (Feb. '62) after the fall of Fort Donelson and remained in their hands till the end. The battle of Nashville was fought (Dec. 15-16, '64) between a Federal army under G. H. Thomas and *Hood's* Army of Tennessee, and resulted in the complete overthrow of the Confederates. *Hood* had reached the Tennessee at Tuscumbia at the end of October, but waited there three weeks to accumulate a stock of supplies and enable *Forrest's* cavalry to join him. This delay proved fatal to his chance of capturing Nashville, before Thomas, whom Sherman had left to meet *Hood's* invasion whilst he himself "marched to sea," could concentrate sufficient forces for its defence. Thomas had under his command two corps

and about 5,000 cavalry under Wilson, in addition to the local garrisons dispersed along the lines of communication from Chattanooga to the Ohio. Until a third corps under A. J. Smith reached him from Missouri (Nov. 30), he can hardly be said to have had a field army at all. *Hood* intended, after capturing Nashville, to invade Kentucky and carry the war to the Ohio. He even contemplated the possibility of marching through the Cumberland mountains to *Lee's* help and attacking Grant. He advanced from the Tennessee (Nov. 21) and endeavoured to outflank Schofield, whom Thomas had placed at Pulaski, 80 m. from Nashville, with the IV. Corps and one division of the XXIII., and about 4,000 cavalry to retard *Hood's* advance, and cut him off from Columbia, where the Nashville railway crossed the Duck river. But Cox's division, by a forced march, saved Columbia from capture by *Forrest*. Wishing to preserve the railway bridge for use when the Federals should take the offensive, Schofield, who had been reinforced by two more infantry brigades, tried to hold on to the south bank, but *Forrest* crossed with his cavalry above the town (Nov. 28), and driving Wilson's mounted troops away from the Franklin road, opened the way for *Hood's* infantry to cut off Schofield's retreat. Next day seven Confederate divisions crossed the river and advanced towards Spring Hill, 11 m. in Schofield's rear, where only a single division was covering the movement of the Federal trains. *Hood* here lost the greatest opportunity offered to any general in the war. He allowed Schofield to escape and make good his retreat to Franklin, on the Harpeth. Schofield was obliged to make another stand there to get his trains across the river. *Hood* made a furious and ill-prepared assault on the strong Federal position late in the afternoon (Nov. 30). The battle raged till 9 p.m., when *Hood* called off his troops, which had suffered terrible losses, and Schofield reached Nashville next day. *Hood's* last chance of conducting a successful offensive was gone, but he continued to follow Schofield and appeared before Nashville (Dec. 2). He believed that retreat would be more demoralizing to his troops than an honourable defeat, and the trans-Mississippi reinforcements promised by the President might yet arrive. Thomas was almost ready to take the offensive. Besides Smith's corps he had just received Steedman's "provisional division" from Chattanooga. He could now put into the field a force probably double the size of *Hood's*. But he needed a few more days in order to remount his large cavalry force, which was intended to play a decisive part in *Hood's* annihilation. Grant grew impatient at the delay. He had expected Thomas to stop *Hood* south of the Duck river, but *Hood* had reached the Cumberland. He bombarded Thomas with telegrams, demanding an immediate attack. Just as Thomas was ready, a storm of freezing rain came on, which covered the ground with a sheet of ice and prevented military operations till a thaw came. Grant ordered (Dec. 9) that Thomas should be superseded by Schofield; suspended the order the same day; ordered (Dec. 13) Logan to Nashville to take command, unless Thomas had moved in the meantime; finally, set out himself to Washington (Dec. 15), intending to go on to Nashville. But the thaw came (Dec. 14) and Thomas attacked next day.

Hood's line ran from the Chattanooga railway on the right across the Franklin and Granny White turnpikes to the Hillsboro' road. His left was sharply refused, extending 1,000 yards behind a stone wall alongside that road. He had thrown up some redoubts on detached hills beyond his left, and established a strong skirmish line along his front, terminating on Montgomery hill, close to the Hillsboro' road. But the line was too long to be held by his attenuated force, and his left was very much "in the air." Having detached *Forrest* with two cavalry divisions to raid the Chattanooga railway, he had but one division left to watch the wide gap between his left and the river. Thomas's plan of battle was to make a grand left wheel with his right wing, consisting of Wilson's 12,000 cavalry, fighting dismounted, and Smith's corps, which should outflank and crush the enemy left, whilst Steedman's division held their right fast by a vigorous demonstration. The IV. Corps under Wood was to storm Montgomery hill and press in upon the Confederate salient on the Hillsboro' road. Schofield's corps was at first held in reserve,

but was finally thrown in between Wilson's and Smith's corps. Had not the Federal advance been delayed by fog in the early morning, Hood would probably have been completely defeated on the 15th. His whole left wing was driven back in great confusion to the Granny White turnpike. Darkness stopped the pursuit, but Hood, who dared not retreat because Forrest could not rejoin for at least 24 hours, during the night formed a fresh and much shorter line 2 m. further back, each flank resting upon a hill. Cheatham's corps was shifted from the right to the left, which again was sharply bent back just beyond the Granny White turnpike, and extended to the Brentwood hills along a line of lesser heights. S. D. Lee's, which had scarcely fired a shot the previous day, held the right, and A. P. Stewart's, after its heavy defeat, was placed in the centre. But again Wilson's dismounted troopers, fighting their way through the smaller hills, turned the Confederate left, and getting into its rear attacked from behind, whilst Schofield and Smith assaulted its front. Under this double pressure Cheatham's corps broke and with its flight Hood's resistance collapsed, although earlier in the day an attack by Wood and Steedman on the right had been handsomely repulsed. His army fled down the Franklin turnpike, the only line of retreat left. But two brigades, which retained their organization, and Chalmers's cavalry division held the Brentwood hill's passes long enough to enable the larger part of Hood's army to escape. The Federals took up the pursuit next day, hoping to intercept the flying enemy on the Duck river, but Forrest, who rejoined Hood at Columbia, organized a rearguard with his cavalry and eight infantry brigades under Walthall, and covered the retreat to the Tennessee, which was recrossed (Dec. 27). Thomas's fighting force at Nashville numbered between 50,000 and 55,000 men; his casualties were just over 3,000. Hood estimated his own force at 23,000, but this is almost certainly an understatement; some authorities put it as high as 39,000. He made no return of his casualties, but stated that they were "very small." But Thomas captured nearly 4,500 prisoners in the battle itself, and many more were taken during the ten days' pursuit.

(W. B. Wo.)

NASI, JOSEPH (16th century), Jewish statesman and financier, was born in Portugal of a Jewish (Marano) family. Emigrating from his native land, he founded a banking house in Antwerp. Despite his financial and social prosperity there, he felt it irksome to be compelled to wear the guise of Catholicism, and determined to settle in a Mohammedan land. After two troubled years in Venice, Nasi betook himself to Constantinople. Here he proclaimed his Judaism, and married his beautiful cousin Reyna. He rapidly rose to favour, the sultans Sulciman and Selim promoting him to high office. He founded a Jewish colony at Tiberias which was to be an asylum for the Jews of the Roman Campagna. In 1566 when Selim ascended the throne, Nasi was made duke of Naxos. He had deserved well of Turkey, for he had conquered Cyprus for the sultan. Nasi's influence was so great that foreign powers often negotiated through him for concessions which they sought from the sultan. Thus the emperor of Germany, Maximilian II., entered into direct correspondence with Nasi; William of Orange, Sigismund August II., king of Poland, also conferred with him on political questions of moment. On the death of Selim in 1574, Nasi receded from his political position, but retained his wealth and offices, and passed the rest of his life at Belvedere (Constantinople). He died in 1579.

(I. A.)

NASIK, a town and district of British India, in the central division of Bombay. The town is on the Godavari river, connected by a tramway (6 m.) with Nasik Road railway station, 107 m. N.E. of Bombay. Pop. (1921) 38,230. It is a very holy place of Hindu pilgrimage, being 18 m. from the source of the Godavari, and a large number of Brahman priests live here. Shrines and temples line the river banks, and in the vicinity there are a number of sacred caves, among which those of Pandu Lena are the most noteworthy. They are ancient Buddhist caves dating from the 3rd century before Christ to the 6th century after, with numerous inscriptions of the highest historical value. Nasik has manufactures of brass and copper ware, and there is a government

distillery at Nasik Road.

The DISTRICT OF NASIK has an area of 5,877 sq.m. With the exception of a few villages in the west, the whole district is situated on a tableland from 1,300 to 2,000 ft. above sea-level. The western portion is hilly, and intersected by ravines. The eastern tract is open, fertile and well cultivated. The Sahyadri range stretches from north to south; the watershed is formed by the Chander range, which runs east and west. All the streams to the south of that range are tributaries of the Godavari. To the north of the watershed, the Girna and its tributary the Mosam flow through fertile valleys into the Tapti. The Girna Left Bank Canal, irrigating some 4,000 acres, was opened in 1909. It contains several old hill forts, the scenes of many engagements during the Mahratta wars. Nasik district became British territory in 1818 on the overthrow of the peshwa. The population in 1921 was 832,576. The principal crops are millet, wheat, pulse, oil-seeds and cotton and fine grapes and vegetables are grown. There is a trade in copper and brass ware, and sugar cane. There are railway workshops at Igatpuri. At Sharanpur is a Christian village, with an orphanage of the Church Missionary Society. The district is crossed by the main line of the Great Indian Peninsula railway.

NASMYTH, ALEXANDER (1758-1840), Scottish portrait and landscape painter, was born in Edinburgh on Sept. 9, 1758. He studied at the Trustees' Academy under Runciman, and became apprenticed as heraldic painter to a coach-builder. At the age of 16 he attracted the attention of Allan Ramsay, who took him to London, and employed him upon the subordinate portions of his works. Nasmyth returned to Edinburgh in 1778, and was soon largely patronized as a portrait painter. He also assisted Mr. Miller of Dalswinton, as draughtsman, in his mechanical researches and experiments; and through his generosity was able to go to Italy, where he remained two years. On his return he painted the portrait of Burns, now in the Scottish National Gallery and well known through Walker's engraving. Nasmyth's pronounced Liberal opinions gave offence to many of his aristocratic patrons, and led to the diminution of his practice as a portraitist. In his later years, accordingly, he worked mainly at landscapes, and occasionally at scene-painting. He has been styled the "father of Scottish landscape art." His subjects are carefully finished and coloured, but are wanting in boldness and freedom.

Nasmyth was also largely employed by noblemen throughout the country in the improving and beautifying of their estates, in which his fine taste rendered him especially skilful. As an architect, he is known for his designs for the Dean Bridge, Edinburgh, and the graceful circular temple covering St. Bernard's Well. Nasmyth died in Edinburgh on April 10, 1840. His youngest son, James, was the well-known inventor of the steam-hammer. His eldest son, Patrick (1787-1831), became a clever landscapist.

For an account of the Nasmyth family see James Nasmyth's *Autobiography* (1883).

NASMYTH, JAMES (1808-1890), Scottish engineer, inventor of the steam-hammer, was born in Edinburgh on Aug. 19, 1808, and was the youngest son of Alexander Nasmyth, the "father of Scottish landscape art." He started business in Manchester on his own account in 1834, and in a few years he was at the head of the prosperous Bridgewater foundry at Patricroft, from which he was able to retire in 1856 with a fortune. The invention of the steam-hammer, with which his name is associated, was actually made in 1839, a drawing of the device appearing in his note-book, or "scheme-book," as he called it, with the date Nov. 24 of that year. It was designed to meet the difficulty experienced by the builders of the "Great Britain" steamship in finding a firm that would undertake to forge the large paddle-wheel shaft required for that vessel, but no machine of the kind was constructed till 1842. In that year Nasmyth discovered one in Schneiders' Creuzot works, and he found that the design was his own and had been copied from his "scheme-book." Apparently, however, he was anticipated in the idea by James Watt. Nasmyth did much for the improvement of machine-tools, and his inventive genius devised many new appliances—a planing-machine ("Nasmyth steam-arm"), a nut-shaping machine, steam pile-driver, hydraulic machinery for various purposes, etc. On his retirement

he lived at Penshurst in Kent, and amused himself with the study of astronomy, and especially of the moon, on which he published a work, *The Moon considered as a Planet, a World and a Satellite*, in conjunction with James Carpenter in 1874. He died in London on May 7, 1890.

His *Autobiography* (edit. Samuel Smiles) was published in 1883.

NASR-ED-DIN [NĀSIRU'D-DĪN] (1829-1896), shah of Persia, was born on April 4, 1829. His mother, a capable princess of the Kajar family, persuaded Shah Mohammed, his father, to appoint him heir apparent, in preference to his elder brothers; and he was accordingly made governor of Azerbaijan. His succession to the throne, Oct. 13, 1848, was vigorously disputed, especially by the followers of the reformer El Bab, upon whom he wreaked terrible vengeance. In 1855 he reestablished friendly relations with France, and coming under the influence of Russia, signed a treaty of amity on Dec. 17 with that power, but remained neutral during the Crimean War. In 1856 he seized Herat, but a British army under Outram landed in the Persian gulf, defeated his forces and compelled him to evacuate the territory. The treaty of peace was signed at Paris, on March 4, 1857, and to the end of his reign he treated Great Britain and Russia with equal friendship. In 1866 the shah authorized the passage of the telegraph to India through his dominions and reminted his currency in the European fashion. In 1873, and again in 1889, he visited England in the course of his three sumptuous journeys to Europe, 1873, 1878, 1889.

The only results of his contact with Western civilization appear to have been the proclamation of religious toleration, the institution of a postal service, accession to the postal union and the establishment of a bank. He gave the monopoly of tobacco to a private company, but was soon compelled to withdraw it in deference to the resistance of his subjects. Abstemious in habits, and devoted to music and poetry, he was a cultured, able and well-meaning ruler, and his reign, already unusually long for an Eastern potentate, might have lasted still longer had it not been for the unpopular sale of the tobacco monopoly, which was probably a factor in his assassination at Teheran on May 1, 1896, by a member of the Babi faction. He was succeeded by his son Muzaffar-ed-din.

NASRIDES, THE, of Granada, were the last of the Mohammedan dynasties in Spain. They ruled from 1232 to 1492. The dynasty was of remote Arabic origin, but its immediate source was the mountain range of the Alpujarra, and the founder was Yusuf (or Yahia) I'Nasr, a chief who was engaged in conflict with the family of Beni-Hud, once kings at Saragossa, who held the fortress of Granada. Yusuf's nephew (or son) Mohammed completed the defeat of the Beni-Hud largely by the help of the king of Castile, to whom he did homage and paid tribute. From Mohammed I., called el Ghalib, *i.e.*, the Conqueror (1238-73), to Mohammed XI., called Boabdil, and also the little king "El Rey Chico" by the Christians, who lost Granada in 1492, there are counted 29 reigns of the Nasrides, giving an average of nine years. But there was not the same number of sultans, for several of them were expelled and restored two or three times. There were also contemporary reigns in different parts, and tribal or local rivalries between plain and hill, and the chief towns, Granada, Malaga and Guadix. The dissensions of the Nasrides reached their greatest pitch of fury during the very years in which the Catholic sovereigns were conquering their territory piecemeal, 1482-92.

See M. Lafuente Alcantara, *Historia de Granada* (Granada, 1884); S. Lane-Poole, *The Mohammedan Dynasties* (1894).

NASSAU, a territory of Germany, now forming the bulk of the government district of Wiesbaden, in the Prussian province of Hesse-Nassau, but until 1866 an independent and sovereign duchy of Germany. It consists of a territory, 1,830 sq.m. in area, divided into two nearly equal parts by the river Lahn and bounded on the south and west by the Main and Rhine, on the north by Westphalia and on the east by Hesse. The southern half is almost entirely occupied by the Taunus mts., while to the north of the Lahn is the barren Westerwald. The valleys and low-lying districts, especially the Rheingau, are very fertile, produc-

ing abundance of grain, flax, hemp and fruit; but by far the most valuable product of the soil is its wine. Nassau is one of the most thickly wooded regions in Germany, and its forests yield good timber and harbour large quantities of game while the rivers abound in fish. There are upwards of a hundred mineral springs in the district; the best known are those of Wiesbaden and Ems. Other mineral wealth of Nassau includes iron, lead, copper, building stone, coals, slate, a little silver and a bed of malachite. Manufactures are unimportant, but brisk trade is carried on by rail and river in wine, timber, grain and fruit. There are few places of importance besides the above-named spas; Höchst is the only manufacturing town. Wiesbaden is the capital of the government district as it was of the duchy.

History.—During the Roman period the whole of the district of Nassau was occupied by the Mattiaci and later by the Alamanni. The latter were subdued by the Franks under Clovis at the end of the 5th century, and at the partition of Verdun in 843 the country became part of the East Frankish or German kingdom. Christianity seems to have been introduced in the 4th century. The founder of the house of Nassau is usually regarded as a certain Drutwin (d. 1076), who built a castle on a hill overlooking the Lahn, near the present town of Nassau. Drutwin's descendant Walram (d. 1198) took the title of count of Nassau, and placed his lands under the immediate suzerainty of the German king; previously he had been a vassal of the archbishop of Trier. Then in 1255 Walram's grandsons, Walram and Otto, divided between them their paternal inheritance, which had been steadily increasing in size. Walram took the part of Nassau lying on the left bank of the Lahn and made Weisbaden his residence; Otto took the part on the right bank of the river and his capital was Siegen. The brothers thus founded the two branches of the house of Nassau.

The fortunes of the Ottonian, or younger line, belong mainly to the history of the Netherlands. William the Silent, the best known of this line, and his descendants were called princes of Orange-Nassau, and this line became extinct when the English king William III. died in 1702. The descendants of Count John, his brother, remained rulers of Nassau until 1806, when the reigning prince, William VI., was deprived of his lands because he refused to join the Confederation of the Rhine. Some of them were given in 1815 to the other main line of the family, the one descended from Count Walram. In 1815 William VI. became king of the Netherlands as William I., and was compensated for this loss by the grant of parts of Luxemburg and the title of grand-duke. When in 1890 William's male line died out Luxemburg, like Nassau, passed to the descendants of Count Walram. In the female line he is now represented by the queen of the Netherlands.

The territories possessed by the other branch of the house of Nassau were partitioned several times, and only in 1816 was the whole of Nassau united under the rule of Frederick William of Nassau-Weilburg as duke of Nassau. In 1866 Duke Adolph espoused the cause of Austria, sent his troops into the field, and asked the landtag for money. This was refused; Adolph was soon a fugitive before the Prussian troops, and on Oct. 3, 1866, Nassau was formally incorporated with the kingdom of Prussia.

For the history of Nassau see Hennes, *Geschichte der Grafen von Nassau bis 1255* (Cologne, 1843); von Schütz, *Geschichte des Herzogtums Nassau* (Wiesbaden, 1853); von Witzleben, *Genealogie und Geschichte der Fürstenhäuser Nassau* (Stuttgart, 1855); F. W. T. Schliephake and K. Menzel, *Geschichte von Nassau* (Wiesbaden, 1865-89); the *Codex diplomaticus nassoicus*, ed. K. Menzel and W. Sauer (1885-87); and the *Annalen des Vereins für nassauische Altertumskunde und Geschichtsforschung* (1827 f.).

NAST, THOMAS (1840-1902), American caricaturist, was born on Sept. 27, 1840, in Landau, Germany. His mother took him to New York in 1846. He studied art there with Theodore Kaufmann and at the school of the National Academy of Design. At the age of 15 he became a draughtsman for *Frank Leslie's Illustrated Newspaper*; three years later for *Harper's Weekly*. In 1860 he went to England for the *New York Illustrated News* and soon afterwards joined Garibaldi in Italy as artist for *The Illustrated London News*. His first serious work was the cartoon "Peace" in 1862, directed against those in the North who opposed the prosecution of the Civil War. This and his other car-

toons during the Civil War and Reconstruction days were published in *Harper's Weekly*; they attracted great attention, and Nast was called by President Lincoln "our best recruiting sergeant." Even more able were Nast's cartoons against the Tweed Ring conspiracy in New York city, his caricature of Tweed being the means of the latter's identification and arrest at Vigo. He had been an ardent Republican in his earlier years; but his advocacy of civil service reform and his distrust of Blaine forced him to become a Mugwump and in 1884 an open supporter of the Democratic Party, from which in 1892 he returned to the Republican Party. He had lost practically all of his earnings by the failure of Grant and Ward, and in May, 1902, was appointed consul general at Guayaquil, Ecuador, where he died on Dec. 7, in the same year. He did some painting in oil and some book illustrations, but his fame rests on his caricatures and political cartoons. Nast introduced the donkey to typify the Democratic Party, the elephant to typify the Republican Party, and the tiger to typify Tammany Hall.

See A. B. Paine, *Thomas Nast, his Period and his Pictures* (1904).

NASTURTIIUM or **INDIAN CRESS**, *Tropaeolum majus*, a perennial climber, native of Peru, but in cultivation treated as a hardy annual. It climbs by means of the long stalk of the peltate leaf which is sensitive to contact like a tendril. The irregular flowers have five sepals united at the base, the dorsal one produced into a spur; of the five petals the two upper are slightly different and stand rather apart from the lower three; the eight stamens are unequal and the pistil consists of three carpels which form a fleshy fruit. The flowers are sometimes eaten in salads, and the leaves and young green fruits are pickled in vinegar as a substitute for capers.

The dwarf form known as Tom Thumb (*T. m. nanum*), is an excellent bedding or border flower, growing about a foot high. Other fine annual tropaeolums are *T. Lobbianum* with long spurred orange flowers and numerous varieties; and *T. minus*, a kind of miniature *T. majus* with yellow, scarlet and crimson varieties.

The genus *Tropaeolum* (family Tropaeolaceae), native to South America and Mexico, includes about 50 species of generally climbing annual and perennial herbs with orange, yellow, rarely purple or blue, irregular flowers; *A. peregrinum* is the well-known canary creeper. The flame nasturtium with brilliant scarlet blossoms is *T. speciosum* from Chile; it has tuberous roots, as have also such well-known perennials as *T. polyphyllum*, *T. pentaphyllum*. The *Nasturtium* of botanists is a genus of plants of the family Cruciferae; *N. officinale* is the water-cress.

NATAL, a province of the Union of South Africa, is bounded by the Indian ocean, by the Umtamvuna and Umzimkulu rivers, which divide it from the Griqualand East division of Cape Colony, by the Drakensberg, which separates it from Basutoland, the Orange Free State, and part of the Transvaal, and by the Pongola river, the Lebombo range, and, for a short distance, a line of latitude, which mark it off from the Transvaal, Swaziland and Portuguese East Africa. Natal, in this extended and official sense, includes Zululand and Amatongaland. The northern boundary of Natal proper for part of the way is the Tugela. The sea board from the mouth of the Umtamvuna to the mouth of the Tugela is 166 m., and from the Tugela to the Portuguese border near Ore Point, 210 miles. Its total area is 35,284 sq.m., or 7.47% of the Union, while it carries a little over 20% of the Union's population. The area of Natal proper is 24,910 sq. miles.

Geologically, the country consists of a monoclinical fold affecting Karroo rocks. Along the axis, which runs more or less north and south, these have been eroded and the underlying rocks of the Swaziland system (granite, schists, etc.) have been exposed along a fairly continuous belt, which can be followed from a point, 5 or 6 m. inland from Port Shipstone, through Inchanga, the Valley of a Thousand Hills, and on into Zululand, where their area broadens out. A great part of the country is formed of horizontal, or gently inclined shales and sandstones, among which numerous sills of dolerite are intercalated. Erosion, attacking these beds, has produced a distinctly terraced topography. The hills are often steep-sided and flat-topped.

Conventionally, three zones are distinguished: (a) the Coast belt below 1,000 ft., which is about 20 m. wide behind Durban, and which narrows southward, and widens considerably when followed northward and into Zululand. (b) The Midlands, between 2,000 and 4,000 feet. (c) The Highlands from 4,000 ft. to the foot of the Drakensberg. This classification is over simplified, but may serve as a rough indication of the build of the country. The rivers, owing to rejuvenation, have cut deep valleys in their lower courses, with the result that the topography of the coast belt and part of the midlands is very broken. In their middle, and in part of their upper courses, the rivers flow in broad, open valleys. Owing to their high average gradient, and the numerous waterfalls, due to the outcropping of hard beds of sandstone and dolerite, and also to their low winter level, they are all unnavigable, except for stretches of 3 or 4 m. at the mouths of the Umkomaas and Umzimkulu. The dominant topographical feature is the great barrier of the Drakensberg (*q.v.*), which rises to over 10,000 ft., and from which several secondary ranges run out toward the coast. The Lebombo range, in the north runs from north to south, and is caused by the outcrop of resistant lavas. Rivers, such as the Usutu and the Pongola cut across this escarpment in great "poorts."

Climate and Vegetation.—These are described under UNION OF SOUTH AFRICA. Owing to the range of altitude from sea-level to 5,000 or 6,000 ft. at the foot of the Drakensberg, there is a wide range of climate, which is further complicated by the varied topography. Always, however, the sub-tropical coast belt stands out as a distinct natural region, with its humid heat, small temperature ranges and its sub-tropical vegetation and production. Inland, the winter drought becomes more clearly marked and frosts more frequent and severe during the winter nights. The chief rain-bearing wind is from the south-west. A very characteristic feature of the Natal climate is the "hot winds," which are usually most frequent in spring and summer. They appear to be due to the flow of air being drawn toward depressions passing southward along the coast. They blow from the north-west and are heated by compression as they descend the escarpments. The temperature often rises above 90° and the relative humidity may fall to 30. A hot wind may blow for a few hours, or for two or three days. It causes great clouds of dust, and all doors and windows in the houses have to be closed. Usually these winds change suddenly, or are replaced by a cool, moist wind from the south-west, which often brings greatly appreciated rain, or sometimes, in the higher districts, snow.

In addition to the trees, shrubs and grasses, described elsewhere, mention may be made of the flowers, which are often beautiful. Some of these, like the red bush lily, grow in the shade of the patches of bush. Others are more tolerant of light, and are to be found in the open. Among these are the fire lily, which blooms in the early spring before the grasses have grown beyond a few inches, the agapanthus, the arum lily along the streams, the gladioli, etc. A very common grassland flower, and one that blooms late, when the grasses are tall, is the leonotis, which attains a height of 5 or 6 ft., and has terra-cotta to orange-coloured flowers. Many a hillside in early spring is enlivened by the flowers of the aloes, in various shades of red. The delightfully rich crimson of the Kafir boom blossoms is peculiarly characteristic of much of Natal.

Fauna.—(See also UNION OF SOUTH AFRICA.) Some of the smaller buck have increased of late years, owing to the cover afforded them by the large wattle plantations. Jackals are undesirably numerous in some of the upland districts, and they often destroy many lambs. Otters occur in some of the rivers. Snakes are common. The chief sporting birds are the quail, partridge and guinea fowl. About 450 sq.m. of country have been set aside as game reserves, in which no animals may be killed at any time. There are several such reserves, one near Giants' Castle, to protect the surviving eland, and one on the Mkusi, in Zululand, where the inyala (buck) still survives, as well as impala, the Zululand suni, etc. Reserves have been established in the Klip River and the Umgeni districts. In addition, several animals and birds have been declared royal game, and cannot be shot

or captured. They include the white, or square-lipped, rhinoceros, which is still found in Zululand, the elephant, female eland, the impala, inyala, roan antelope, springbok, sassaby; crested crane, Stanley crane, etc.

Population.—The natives (*see* AMAZULU, KAFIRS, etc.) numbered (1921) 1,139,804, and constituted nearly 80% of the total population. About half of them live under tribal conditions on locations, which are saturated with population, under present conditions of skill and methods of exploitation. The other half live on farms, owned by Europeans, on Crown lands, or in the towns. In 1921 the Asiatic population numbered 141,649. It is largely concentrated in the coastal belt. Originally imported as indentured labourers for the sugar plantations, many of these Indians have become small market gardeners, or have taken employment in hotels and domestic service or industry, where they supply much of the unskilled and semi-skilled labour. The British elements constitute the majority of the white population, English predominating. The "northern districts," Utrecht and Vryheid, however, are chiefly Dutch in population, language and religion. In recent years the percentage of Dutch to the total population has probably increased, owing to the considerable numbers employed in the Government services, such as railways, police, etc. There is a definite German group, centred about New Hanover, and retaining its own language. Scandinavian settlers about the Umzimkulu, and in Durban, especially connected with the whaling industry, contribute a very valuable element to the population. There is also an appreciable French element, which originally migrated to Natal, largely from Mauritius, in connection with the sugar industry, though it is no longer confined to that industry. The number of "coloured" people in Natal is quite small, the "mixed and others" in 1921 numbering about 11,000.

Towns.—Apart from Pietermaritzburg, the capital, and Durban (*q.v.*), the only port and the largest centre, the towns of Natal are quite small. Only four, in addition to the two just mentioned, have a white population of over 2,000. They are: Ladysmith, whites (1926) 3,547; total (1921) 6,783, which is now a railway centre of some importance; Glencoe, whites (1926) 2,927; total (1921), 1,212, including 552 whites, a railway junction, and near the coal fields; Vryheid, whites (1926) 2,842; total (1921) 4,019; and Newcastle, whites (1926) 2,355; total (1921) 5,767. The last two towns are also near coal mines, and Newcastle is developing an iron and steel industry.

Communications.—Railway construction has been greatly handicapped by the varied topography. The main line from Durban to the Transvaal climbs to 1,808 ft. at Krautzkloof (23 m.), 3,006 ft. at Thornville Junction (61 m.), drops to 2,218 at Pietermaritzburg (73 m.), rises to 3,702 at Hilton Road (84 m.), to 4,807 at Nottingham Road (116 m.), drops to 3,280 ft. at Colenso (185 m.), and rises again to 5,429 ft. at Volksrust, just over the Transvaal border, and to 5,520 at Van Reenens, just within the Orange Free State. From the main system a line runs from Durban along the coast southward to Port Shepstone, and northward as far as the Pongola in Zululand to serve the sugar cane area. From Pietermaritzburg a line with two short branches has been constructed to Krantzkop through the wattle belt. Another runs south westward across the grain of the country to open up East Griqualand; from Glencoe Junction a line, running through Dundee and Vryheid, carries large quantities of coal. There are a few other smaller lines, which can be seen on a map. As in other parts of the world, the railways are feeling the effect of motor competition along some stretches. The journey by road from Pietermaritzburg to Durban is shorter and quicker than by rail.

Agriculture.—The coast belt is sharply marked off from the rest of the country. It produces sugar, bananas, pineapples, citrus fruit, etc. Practically all the cane grown is of the Uba variety. In 1926 there were 231,967 ac. under this crop, and the production of sugar for the year 1925-26, was 239,851 tons (*i.e.*, of 2,000 lb.). The industry now satisfies the requirements of the South African market, and has a surplus for export. Among the by-products are molasses, used for cattle feeding, and also

exported, motor spirit, produced from the molasses, methylated spirits, ether and wax. Rather more than 3,000 ac. in the Kearsney-Stanger area are devoted to tea growing. In 1925-26 the production of green leaf was 4,000,000 lb., of manufactured tea 852,799 lb. The industry shows little sign of growing. The rest of Natal is devoted to mixed farming, with increasing stress

'RICKSHA "BOY" OF DURBAN.
NATAL

being laid on dairying. Maize thrives particularly well in the Midlands, but little of this grain is exported, because it is often sold by the white farmers to the natives, whose own food production is insufficient. Between 2,000 and 6,000 ft. the Australian black wattle is grown, especially in the mist belts along the escarpments. From the bark an extract is made which is used in tanning. The poles supply the mines with pit props, and the towns with much of their domestic fuel. There is a wattle belt, fairly well defined in the midlands of Natal, through the middle of which runs the Richmond-Pietermaritzburg-Greytown-Krantzkop railway. The wattle plantations cover 220,000 ac., and in 1926 the quantity of bark exported from the country was over 90,000 tons, Great Britain, Belgium, Germany and Japan being the chief customers. Wattle extract is also exported. Cotton growing appears to have passed the experimental stage. It is being grown in some of the northern and eastern districts of Natal and in Zululand. In 1925-26, 41,000 ac. were being cultivated for this crop. The growing of tobacco has been stimulated by the introduction of a preferential tariff for Empire tobacco in Great Britain in 1925. The chief mineral produced in the country is coal. Many of the deposits have been metamorphosed by the intrusion of dolerite, but large quantities are available for exploitation. The chief coalfield is in the Klip River and Newcastle districts, centring about Dundee. Mines are also active in the Vryheid and Utrecht districts. The expense of the long railway journey to the coast, on the average about 240 m., is partially counterbalanced by the nearness of the coal to the surface. In 1926 the output was over five million tons. At Waschbank the following by-products are being produced: tar, sulphate of ammonia, light creosote oil and naphtha. Tar is also being made.

Education.—For higher education *see* UNION OF SOUTH AFRICA. The direction of public education, other than higher education, rests with the Provincial Education Department, subject to the control of the provincial administration. At its head is the superintendent of education. The department has direct management of primary and of some secondary schools, and makes grants to various private schools, which maintain the same standard as the Government schools. Fees are charged for pupils in the secondary schools. Special schools are provided for native, coloured and Indian children. Attendance is compulsory for children between 7 and 15, who live within the three-mile limit. A Government training college for teachers is situated in Pietermaritzburg. In the latter city there is also a technical institute, and in Durban a technical college. In addition to the Government schools, there are several good schools in the province, both for boys and girls, which are modelled on the English public school. An agricultural college, connected with a Government experimental farm, was opened in 1906 at Cedara, 14 m. from Pietermaritzburg.

To meet some of the requirements of the non-European population, there were, in 1925, 492 State and State-aided schools for natives, 52 for Asiatics, and 22 for other non-Europeans. These were attended by 31,247 natives, 8,520 Asiatics and 2,025 coloured pupils. (*See* also UNION OF SOUTH AFRICA.) (R. U. S.)

HISTORY

Vasco da Gama on his voyage to India sighted the bluff at the entrance to the bay now forming the harbour of Durban on Christmas Day 1497 and named the country Terra Natalis. Da Gama made no landing here and, like the rest of South Africa, Natal was neglected by the Portuguese, whose nearest settlement was at Delagoa bay. The first detailed accounts of the country were received from mariners. In 1684 an English ship put into Port Natal (as the bay came to be known) and purchased ivory from the natives, who, however, refused to deal in slaves. In May 1685 another English ship the "Good Hope" was wrecked in crossing the bar at Port Natal and in Feb. 1686 the "Stavenisse," a Dutch East Indiaman, was wrecked a little farther south. Survivors of both vessels lived for nearly a year at Port Natal and there built a boat in which they made the voyage to Cape Town in twelve days. They brought with them three tons of ivory. This fact and their reports of the immense herds of elephants which roamed the bush led Simon van der Stell, then governor at Cape Town to despatch (1689) the ship "Noord" to Port Natal, with instructions to her commander to open up a trade in ivory and to acquire possession of the bay. The bay was "purchased" from the chief of the Amatuli tribe, for about £50 worth of goods. No settlement was then made and in 1705 the son of the chief repudiated the bargain. In 1721 the Cape Government did form a settlement at the bay, but it was soon afterwards abandoned. Thereafter for nearly a hundred years Natal was again neglected by white men.

From the records of the 17th and 18th centuries it is apparent that the people then inhabiting Natal were Bantu-negroes of the Kafir (Ama Xosa) branch. The most numerous and most powerful tribe appeared to be the Abambo, while the Amatuli occupied a considerable part of the coast-land. These Kafirs seem to have been more given to agriculture and more peaceful than their neighbours in Caffraria and Cape Colony. But the quiet of the country was destroyed by the inroads of Chaka, the chief of the Zulus (*see* ZULULAND). Chaka between 1818 and 1820 ravaged the whole of what is now known as Natal, and after beating his foes in battle, butchered the women, children and old men, incorporating the young men in his impis. The population was greatly reduced and large areas left without a single inhabitant. By right of conquest Chaka became undisputed master of the country.

First British Settlement.—Such was the situation when the first British settlement was made in Natal, Cape Colony having passed meanwhile from Dutch to British possession. In 1823 Francis George Farewell, formerly a lieutenant in the British navy, with other merchants of Cape Town, formed a company to trade with the natives of the south-east coast. In the brig "Salisbury," commanded by James S. King, who had been a midshipman in the navy, Farewell visited Port Natal, St. Lucia and Delagoa Bays. He was so impressed with the possibilities of Natal both for trade and colonization that he resolved to establish himself at the port. He went thither with ten companions, among them Henry Francis Fynn. All the rest save Farewell and Fynn speedily repented of their adventure and returned to the Cape, but the two who remained were joined by three sailors, John Cane, Henry Ogle and Thomas Holstead, a lad. Farewell, Fynn and others went to the royal kraal of Chaka, and, having cured him of a wound and made him various presents, obtained a document, dated Aug. 7, 1824, ceding to "F. G. Farewell and company entire and full possession in perpetuity" of a tract of land including "the port or harbour of Natal." On the 27th of the same month Farewell hoisted the Union Jack at the port and declared the territory he had acquired a British possession. In 1825 he was joined by King, who had meantime visited England and had obtained from the Government a letter of recommendation to Lord Charles Somerset, governor of the Cape, granting King permission to settle at Natal. Farewell, King and Fynn made independent settlements at various parts of the bay, where a few Amatuli still lingered. They lived, practically, as Kafir chiefs, trading with Chaka and gathering round them many

refugees from that monarch's tyranny. Early in 1828 King, accompanied by two of Chaka's indunas, voyaged in the "Elizabeth and Susan," a small schooner built by the settlers, to Port Elizabeth. He appears to have been coldly received by the authorities. Soon after his return to Natal King died, and in the same month (Sept. 1828) Chaka was murdered by his brother Dingaan. In the December following Farewell went in the "Elizabeth and Susan" to Port Elizabeth. On this occasion the authorities confiscated the schooner on the ground that it was unregistered and that it came from a foreign port. Farewell was not daunted, and in Sept. 1829 set out to return overland to Port Natal. He was, however, murdered in Pondoland by a chief who was at enmity with the Zulus. Fynn thus became leader of the whites at the port, Dingaan declaring him to be his representative and "great chief of the Natal Kafirs." In 1834, however, Fynn accepted a post under the Cape government and did not return to Natal for many years. It was in this year that a petition from Cape Town merchants asking for the creation of a British colony at Natal was met by the statement that the Cape finances would not permit the establishment of a new dependency.

The next step was taken by the settlers at the port, who in 1835 resolved to lay out a town, which they named Durban, after Sir Benjamin d'Urban, then governor of Cape Colony. The settlers, who numbered about 50, sent a memorial to the governor calling attention to the fact that they were acknowledged rulers over a large tract of territory south of the Tugela, and asking that this territory should be proclaimed a British colony under the name of Victoria and that a governor and council be appointed. To all these requests no official answer was returned. The settlers had been joined in the year named (1835) by Captain Gardiner, a naval officer, whose chief object was the evangelization of the natives. With the support of the traders he founded a mission station in the hills (which he named Berea) overlooking the bay. In 1837 Gardiner was given authority by the British Government to exercise jurisdiction over the traders. They, however, refused to acknowledge Gardiner's authority, and from the Cape government he received no support.¹ It was not until their hand was forced by the occupation of the interior by Dutch farmers that the Cape authorities at length intervened.

The Dutch and Dingaan.—The British settlers had, characteristically, reached Natal mainly by way of the sea; the new tide of immigration was by land—the *voortrekkers* streamed through the passes of the Drakenberg, bringing with them their wives and children and vast herds of cattle. The reasons which caused the exodus from the Cape are discussed elsewhere (*see* SOUTH AFRICA, UNION OF, and CAPE COLONY); here it is only necessary to point out that those emigrants who entered Natal shared with those who settled elsewhere an intense desire to be free from British control. The first emigrant Boers to enter the country were led by Pieter Retief (*c.* 1780–1838), a man of Huguenot descent and of marked ability, who had suffered severely in the Kafir wars. Passing through the almost deserted upper regions Retief arrived at the bay in Oct. 1837. He went thence to Dingaan's kraal with the object of securing a formal cession of territory to the Dutch farmers. Dingaan consented on condition that the Boers recovered for him certain cattle stolen by another chief; this task Retief accomplished, and with the help of the Rev. F. Owen, an Anglican missionary then living at Dingaan's kraal, a deed of cession was drawn up in English and signed by Dingaan and Retief on Feb. 4, 1838. Two days after the signature of the deed Retief and all of his party, 66 whites, besides Hottentot servants, were treacherously murdered by Dingaan's orders. The Zulu king then commanded his impis to kill all the Boers who had entered Natal. The Zulu forces crossed the Tugela the same day, and the most advanced parties of the Boers were massacred, many at a spot near where the town of Weenen now stands, its name (meaning weeping or weeping) commemorating the event. In one week after the murder of Retief

¹Captain Allen Francis Gardiner (1794–1851) left Natal in 1838, subsequently devoting himself to missionary work in South America, being known as the missionary to Patagonia. He died of starvation in Tierra del Fuego.

600 Boers—men, women and children—had been killed by the Zulus. The English settlers at the bay with a following of some 700 natives, made an attempt to aid the Boers, but in a fight on April 7 they were overwhelmed and only four Europeans escaped to the bay.

After the Zulus retired, fewer than a dozen Englishmen returned to live at the port; the missionaries, hunters and other traders went back to the Cape. Meanwhile the Boers, who had repelled the Zulu attacks on their laagers, had been joined by others from the Drakenberg, and about 400 men under Hendrik Potgieter and Piet Uys advanced to attack Dingaan. On April 11, however, they fell into a trap and with difficulty cut their way out. Among those slain were Piet Uys and his son Dirk, aged 15, who rode by his side. Towards the end of the year the Boers received reinforcements, and in December 460 men set out under Andries Pretorius to avenge themselves on the Zulus. On Sunday Dec. 16 (1838) while laagered near the Umslotos river, they were attacked by over 10,000 Zulus. The Boers had firearms, the Zulus their assegais only, and after a three hours' fight the Zulus were totally defeated, losing thousands killed, while the farmers' casualties were under a dozen. (This memorable victory is annually commemorated by the Boers as Dingaan's Day, while the Umslotos, which ran red with the blood of the slain, was renamed Blood river.) Dingaan fled, the victorious Boers entered the royal kraal, gave decent burial to the skeletons of Retief and his party, and regarded themselves as now undisputed masters of Natal.

Returning south, Pretorius and his commando were surprised to learn that Port Natal had been occupied on Dec. 4 by a detachment of the 72nd Highlanders. In sanctioning the occupation of the port the British Government of the day had no intention of making Natal a British colony, but wished to prevent the Boers establishing an independent republic upon the coast with the possibility of complications with other European powers. After remaining at the port just over a year the Highlanders were withdrawn, on Christmas Eve 1839. Meanwhile the Boers had founded Pietermaritzburg and made it the seat of the volksraad. They rendered their power in Natal absolute, for the time, in the following month, when they joined with Panda, Dingaan's brother, in another attack on the Zulu king. Dingaan was utterly defeated and soon afterwards perished, Panda becoming king in his stead by favour of the Boers.

Had the affairs of the Boer community been managed with prudence and sagacity they might have established an enduring state. But their impatience of control, reflected in the form of government adopted, led to disastrous consequences. Legislative power was vested, nominally, in the volksraad (consisting of 24 members), while the president and executive were changed every three months. But whenever any measure of importance was to be decided a meeting was called of *het publiek*, that is, of all who chose to attend, to sanction or reject it and, naturally enough, the result was a condition of anarchy. While such was the domestic state of affairs the settlers cherished large territorial views. They had declared themselves an independent state under the title of "the republic of Port Natal and adjacent countries" (commonly called the republic of Natalia or Natal), and sought (Sept. 1840) from Sir George Napier at the Cape an acknowledgment of their independence by Great Britain. Sir George, being without definite instructions from England, could at first give no decisive answer. Having at length received an intimation from London that the queen "could not acknowledge the independence of her own subjects, but that the trade of the emigrant farmers would be placed on the same footing as that of any other British settlement, upon their receiving a military force to exclude the interference with or possession of the country by any other European power," Sir George communicated this decision to the volksraad in Sept. 1841. The Boers, who strongly resented the contention of the British that they could not shake off British nationality though beyond the bounds of any recognized British possession, after very brief consideration firmly rejected Napier's overtures.

An incident which happened at this time greatly encouraged

the Boers to persist in their opposition. In March 1842 a Dutch vessel sent out by G. G. Ohrig, an Amsterdam merchant who sympathized warmly with the cause of the emigrant farmers, reached Port Natal, and its supercargo, J. A. Smellekamp (a man who subsequently played a part in the early history of the Transvaal and Orange Free State), without any authority, concluded a treaty with the volksraad assuring them of the protection of Holland. The Natal Boers were firmly persuaded that Holland would aid them in resisting Great Britain.

Dick King's Ride.—On May 4 following Captain T. C. Smith with a force of 263 men who, at Sir George Napier's orders had marched overland from Cape Colony, reached Durban without opposition, and encamped at the base of the Berea hills. The Boers, cut off from their port, called out a commando of some 300 to 400 men under Andries Pretorius and gathered at Congella at the head of the bay. After repulsing an attack on their camp the Boers captured the harbour and settlement, and on May 31 blockaded the British camp. Meanwhile an old Durban resident, Richard (commonly called Dick) King, had undertaken to convey tidings of the perilous position of the British force to the commandant at Graham's Town. He started on the night of the 24th, and escaping the Boer outposts rode through the dense bush and across the bridgeless rivers of Caffraria at peril of his life from hostile natives and wild beasts, and in nine days reached his destination—a distance of nearly 600m. by the route to be followed. This remarkable ride was accomplished with one change of mount, obtained from a missionary in Pondoland. A comparatively strong force under Colonel A. J. Cloete was at once sent by sea to Port Natal, and on June 26 Captain Smith was relieved. Within a fortnight Colonel Cloete had received the submission of the volksraad at Pietermaritzburg. The burghers represented that they were under the protection of Holland, but this plea was peremptorily rejected by the commander of the British forces.

The British Government of the day, the second Peel administration, held that the establishment of a colony in Natal would be attended with little prospect of advantage, but in deference to the strongly urged views of Sir George Napier, Lord Stanley (Secretary of State for the Colonies), in a despatch of Dec. 13, received in Cape Town on April 23, 1843, consented to its annexation. The institutions adopted were to be as far as possible in accordance with the wishes of the people, but it was a fundamental condition "that there should not be in the eye of the law any distinction or disqualification whatever, founded on mere difference of colour, origin, language or creed"—a condition not kept in later years. Sir George then appointed Henry Cloete (a brother of Col. Cloete) as special commissioner to explain to the Natal volksraad the decision of the government. Cloete whose task was one of great difficulty and delicacy behaved with the utmost tact and on Aug. 8, 1843, the Natal volksraad unanimously agreed to the terms proposed by Lord Stanley. Many of the Boers who would not acknowledge British rule trekked once more over the mountains into what are now the Orange Free State and Transvaal provinces. At the end of 1843 there were not more than 500 Dutch families left in Natal.

A BRITISH COLONY

Although proclaimed a British colony in 1843, and in 1844 declared a part of Cape Colony, it was not until the end of 1845 that an effective administration was installed with Martin West as lieutenant-governor, and the power of the volksraad finally came to an end. In that year the external trade of Natal, almost entirely with Cape Colony, was of the total value of £42,000—of which £32,000 represented imported goods.

The new administration found it hard to please the Dutch farmers, who among other grievances resented what they considered the undue favour shown to the natives, whose numbers had been greatly augmented by the flight of refugees from Panda. The natives were settled in 1846 in locations and placed under the general supervision of Sir (then Mr.) Theophilus Shepstone (*q.v.*). Sir Harry Smith, newly appointed governor of the Cape, met, on the banks of the upper Tugela, a body of farmers preparing to recross the Drakensberg—which had been fixed as the

northern frontier—and by remedying their grievances induced many of them to remain in Natal. By the migration of the others the whites were again considerably reduced, but the Boers who remained were contented and loyal, and through the arrival of 4,500 emigrants from England in the years 1848–1851 and by subsequent immigration from overseas the colony became overwhelmingly British in character.

From the time of the coming of the first considerable body of British settlers dates the development of trade and agriculture in the colony, followed somewhat later by the exploitation of the mineral resources of the country. At the same time schools were established and various churches began or increased their work in the colony. Dr. Colenso, appointed bishop of Natal, arrived in 1854. In 1856 the dependence of the country on Cape Colony was put to an end and Natal constituted a distinct colony with a legislative council of 16 members, 12 elected by the inhabitants and four nominated by the crown. At the time the white population exceeded 8,000. While dependent on the Cape, ordinances had been passed establishing Roman-Dutch law as the law of Natal, and save where modified by legislation it remained in force.

Indian Coolies Introduced.—The British settlers soon realized that the coast lands were suited to the cultivation of tropical or semi-tropical products, and from 1852 onward sugar, coffee, cotton and arrow-root were introduced, tea being afterwards substituted for coffee. The sugar industry soon became of importance, and the planters were compelled to seek for large numbers of labourers. The natives, at ease in their locations, did not volunteer in sufficient numbers, and recourse was had to coolie labour from India. The first coolies reached Natal in 1860. They came under indentures, but at the expiration of their contract were allowed to settle in the colony. Up to 1869 some 5,000 Indians had come to Natal. Immigration then ceased but was resumed in 1874. This bringing in of Indians proved one of the most momentous steps taken in the history of South Africa, for the Indian population rapidly increased, the “free” Indians becoming market gardeners, farmers, hawkers, traders, and in time serious competitors of the whites. But in 1860 and for many years afterwards these consequences were not foreseen, and alone among the South African states Natal offered a welcome to Asiatics.

In 1867 R. W. Keate (1814–73) became lieutenant-governor, a post which he filled until 1872. His administration is notable, not so much for internal affairs but because he twice acted as arbitrator in disputes in which the Boer states were involved. In a dispute between the Transvaal and the Orange Free State he decided (Feb. 1870) that the Klip river and not the upper Vaal was the frontier stream. A more famous decision, that known as the Keate Award, was given in Oct. 1871. It concerned the southwestern frontiers of the Transvaal, and the award, which was against the Transvaal pretensions, had important effects on the history of South Africa (see GRIQUALAND and TRANSVAAL).

Daring all this time little was done to alter the condition of the natives. There was scarcely an attempt to copy the policy, then followed in Cape Colony, of encouraging the education and civilization of the black man. Neither was Natal faced with the Cape problem of a large half-caste population. While the opportunity of educating and training a docile people was in the main neglected, savage abuse of power by their chiefs was prevented. Under the superintendence of Shepstone the original refugees were quiet and contented. This ideal lot, from the native point of view, drew such numbers of immigrants from disturbed districts that with the natural increase of population in 30 years the native inhabitants increased from about 100,000 to fully 350,000. New generations grew up almost as ignorant as their fathers, but not with the same sense of dependence upon the white men. In this way was sown the seed of future trouble between the two races. The first serious collision between the natives and the government occurred in 1873. The Amahlubi, one of the highest in rank of the Bantu tribes of South Africa, fleeing from the cruelties of Panda, had been located by the Natal government under their chief Langalibalele (*i.e.*, the great sun which shines and burns) in 1848 at the foot of the Drakenberg with the object of preventing the Bushmen who dwell in the mountains plundering the

upland farmers. Here the Amahlubi prospered, and after the diamond fields had been discovered many of the young men who had been to Kimberley brought back firearms. These Langalibalele refused to register, and entered into negotiations with several tribes with the object of organizing a general revolt. Prompt action by Sir Benjamin Pine, then lieutenant-governor of the colony, together with help from the Cape and Basutoland, prevented the success of Langalibalele's plan, and his own tribe, numbering some 10,000 persons, was the only one which rebelled. The chief was captured, and exiled to Cape Colony (Aug. 1874). Permitted to return to Natal in 1886, he died in 1889.

The Colenso Affair.—Meantime the colony had weathered a severe commercial crisis brought on in 1865 through over-speculation and the neglect of agriculture, save along the coast belt. But the trade over berg largely developed on the discovery of the Kimberley diamond mines, and the progress of the country was greatly promoted by the substitution of the railway for the ox wagon as a means of transport. On Jan. 1, 1876, Sir Henry Bulwer, who had succeeded Wolseley as governor, turned the first sod of a new State-owned railway which was completed as far as Maritzburg in 1880. At this date the white inhabitants numbered about 20,000. But besides a commercial crisis the colony had been the scene of an ecclesiastical dispute which attracted widespread attention. Bishop Colenso (*q.v.*), condemned in 1863 on a charge of heresy, ignored the authority of the court of South African bishops and was maintained in his position by decision of the privy council in England. This led to a division among the Anglican community in the colony and the consecration in 1869 of a rival bishop, who took the title of bishop of Maritzburg. (Reunion of the Anglican body in Natal was effected in 1910.) Colenso's bold advocacy of the cause of the natives—which he maintained with vigour until his death (in 1883)—attracted almost equal attention. His native name was Usobantu (*father of the people*).

For some years Natal, in common with the other countries of South Africa, had suffered from the absence of anything resembling a strong government among the Boers of the Transvaal, neighbours of Natal on the north. The annexation of the Transvaal to Great Britain, effected by Sir Theophilus Shepstone in April 1877, would, it was hoped, put a period to the disorders in that country. But the new administration at Pretoria inherited many disputes with the Zulus, disputes which were in large measure the cause of the war of 1879. For years the Zulus had lived in amity with the Natalians, from whom they received substantial favours, and in 1872 Cetywayo (*q.v.*), on succeeding his father Panda, had given assurances of good behaviour. These promises were not kept for long, and by 1878 his attitude had become so hostile towards both the Natal and Transvaal governments that Sir Bartle Frere, then High Commissioner for South Africa, determined on his reduction. During the war (see ZULULAND) Natal was used as the British base, and the Natal volunteers rendered valuable service in the campaign, which, after opening with disasters to the British forces, ended in the breaking of the Zulu power.

Majuba.—Scarcely had the colony recovered from the shock of the Zulu War than it was involved in the uprising of the Transvaal Boers (1880–81). The Natalians were intensely British in sentiment, and resented deeply the policy adopted by the Gladstone administration. At Ingogo, Majuba and Laing's Nek, all of them situated within the colony, British forces had been defeated by the Boers; and the treaty of retrocession was regarded in Natal as an unworthy surrender of British rights. The Natalians nevertheless made up their minds to shape their policy in conformity with that settlement. It was not long before their patience was once more severely taxed. Transvaal Boers, taking advantage of the disputes among the petty Zulu chiefs set up by Sir Garnet Wolseley after the war of 1878–79, intervened (in 1883) and as a reward for the assistance they had rendered to one of the combatants, demanded and annexed 8,000 sq. m. of country, which they styled the “New Republic.” This interference by the Transvaal in Zululand affairs gave great offence in Natal. The “New Republic,” reduced in area, however, to fewer

than 2,000 sq.m., was nevertheless recognized by the British Government in 1886, and in 1888 its consent was given to the territory (the Vryheid district) being incorporated with the Transvaal. Meanwhile in 1887, the remainder of Zululand had been annexed to Great Britain (*see* ZULULAND).

Effect of Discovery of Gold.—In 1884 the discovery of gold in De Kaap Valley, and on Moodie's farm in the Transvaal, caused a considerable rush of colonists from Natal to that country. Natal not only sent her own colonists to the new fields, but also offered the nearest route for prospectors from Cape Colony or from Europe. Two years later the Rand goldfields were proclaimed, and the tide of trade which had already set in with the Transvaal steadily increased. In this year (1886) the railway reached Ladysmith, and in 1891 it was completed to the Transvaal frontier at Charlestown, the section from Ladysmith northward opening up the Dundee and Newcastle coalfields. Thus a new industry was added to the resources of the colony.

The demand which the growing trade made upon the one port of Natal, Durban, encouraged the colonists to redouble their efforts to improve their harbour.

Harbour works had been begun in 1857, but it was chiefly due to the energy of one of Natal's most distinguished sons, Harry Escombe, that Durban was transformed into a modern port. From 1881 to 1893 Escombe was chairman of the Harbour Board.

SELF-GOVERNMENT

For many years there had been an agitation among the colonists for self-government. In 1882 the colony was offered self-government coupled with the obligations of self-defence. The offer was declined, but in 1883 the legislative council was remodelled so as to consist of 23 elected and 7 nominated members. In 1890 the elections to the council led to the return of a majority in favour of accepting self-government, and in 1893 a bill in favour of the proposed change was passed and received the sanction of the imperial Government. At the time the white inhabitants numbered about 50,000. The electoral law was framed to prevent more than a very few Indians and natives obtaining the franchise. Sir John Robinson (1839-1903) who had gone to Natal in 1850, was a leading journalist in the colony and had been a member of the legislative council since 1863, became the first premier and colonial secretary, with Harry Escombe as attorney-general. The year that witnessed this change in the constitution was also notable for the death of Sir Theophilus Shepstone, Natal's most prominent citizen. Sir John Robinson remained premier until 1897, a year marked by the annexation of Zululand to Natal. In the following year Natal entered the Customs Union already existing between Cape Colony and the Orange Free State.

The Anglo-Boer War.—Natal watched with anxiety the increasing tension between the Transvaal and the Cape Colony, and its citizens suffered, equally with other *Uitlanders*, the disabilities imposed by the Pretoria government. As early as May 1899 the Natal ministry officially intimated its belief that the Transvaal would go to war, and while promising every support possible to the imperial Government, expressed anxiety for the defence of the frontier. On Oct. 11, 1899 war broke out, and Natal was invaded by the Boers. The story of the war is told elsewhere (*see* SOUTH AFRICAN WAR; SOUTH AFRICA, UNION OF). A small number of the Dutch colonists joined the enemy but there was no general rebellion among them and the promise that Natal would assist the imperial Government was amply redeemed.

One result of the war was an addition to the territory of Natal of a small part of the Transvaal, namely the district of Vryheid, the district of Utrecht and a portion of the district of Wakkerstroom. As to Vryheid, "in handing over this district to the administration which controls the rest of Zululand, his majesty's Government," wrote Joseph Chamberlain (then Secretary of State for the Colonies), under date March 1902, "feel that they are reuniting what ought never to have been separated." A claim by Natal to annex portions of the Harrismith and Vrede districts of the Free State was, however, disallowed. The districts which were added to Natal contained about 6,000 white inhabitants

(mostly Dutch), and some 92,000 natives, and had an area of nearly 7,000 sq.m., so that this annexation meant an addition to the white population of Natal of about one-tenth, to her native population of about one-tenth also, and to her territory of about one-fourth. The territories were formally transferred to Natal in Jan. 1903.

Native Affairs: The 1906 Revolt.—The period following the war was succeeded by commercial depression. The Government met the crisis by renewed energy in harbour works, railway constructions and the development of the natural resources of the country. A railway to the Zululand coalfields was completed in 1903, and in the same year a line was opened to Vryheid in the newly annexed territories. In Aug. 1903 Sir Alfred Hime, who had been premier since June 1899 resigned and was succeeded by Mr. (afterwards Sir) George Sutton, the founder of the wattle industry in Natal and one of the pioneers in the coal-mining industry. In May 1905 Sir George Sutton was replaced by a coalition ministry under C. J. Smythe, while in 1906 Sir Ralph Moor became premier. These changes of ministry reflected, chiefly, differences concerning the treatment of commercial questions and the policy to be adopted towards the natives. Towards those Dutch colonists who had joined the enemy during the war leniency was shown, all rebels being pardoned. The attitude of the natives both in Natal proper and in Zululand caused much disquiet. The chief concern of the Natal government was to remodel their native policy where it proved inadequate. During 1903-04 a Native Affairs' commission, representative of all the South African states, had obtained much evidence on the status and conditions of the natives. Among its recommendations was the direct political representation of natives in the colonial legislatures on the New Zealand model, and the imposition of direct taxation upon natives. Carrying out this last recommendation Natal passed in 1905 an act imposing a poll-tax of £1 on all males over 18 in the colony, except indentured Indians and natives paying hut-tax (which was 14s. a year). Every European was bound to pay the tax. In 1906 a serious rebellion broke out in the colony, attributable ostensibly to the poll-tax, and spread to Zululand. An incident which marked the beginning of this rebellion brought the Natal ministry into sharp conflict with the imperial Government (the Campbell-Bannerman administration). Twelve natives were to be shot by order of a court martial for killing, at Byrnetown, two Europeans, who had been sent to enforce the collection of the poll-tax. On the day before that fixed for the execution Lord Elgin, then Secretary of State for the colonies, intervened and directed the governor to postpone the execution of the sentence. Thereupon the Natal ministry resigned, giving as their reason the importance of maintaining the authority of the colonial administration at a critical period, and the constitutional question involved in the interference by the imperial authorities in the domestic affairs of a self-governing colony. After a day's delay, during which the governor of Natal, Sir Henry McCallum, reiterated his concurrence, already made known in London, in the justice of the sentence passed on the natives, Lord Elgin gave way (March 30). The Natal ministry thereupon remained in office. The guilty natives were shot on April 2. It was at this time that Bambaata, a chief in the Greytown district who had been deposed for misconduct, kidnapped the regent appointed in his stead. He was pursued and escaped to Zululand, where he received considerable help. He was killed in battle in June, and by the close of July 1906 the rebellion was at an end. As has been stated, it was ostensibly attributable to the poll-tax, but the causes were more deep-seated. Though somewhat obscure they may be found in the growing sense of power and solidarity among all the Bantu tribes of South Africa. There were moreover special local causes such as undoubted defects in the Natal administration. (*See* Governor's despatch, June 21, 1906, printed in the Blue Book, Cd. 3247.) Many Natalians regarded Dinizulu, the son of Cetewayo, as the inciter of the rebellion and after a series of murders of whites in Zululand in 1907, and evidences of continued unrest among the natives the Natal Government itself became convinced that Dinizulu was implicated in a rebellious movement. A force under Sir Duncan McKenzie (who had suppressed the 1906 revolt) entered Zulu-

land. Thereupon Dinizulu surrendered (Dec. 1907) without opposition, and was removed to Maritzburg. He was eventually (1909) found guilty only on the minor charge of harbouring rebels.

The inter-colonial commission had dealt with the native question as it affected South Africa as a whole; it was felt that a more local investigation was needed, and in Aug. 1906 a strong commission was appointed to inquire into the condition of the Natal natives. The commission, whose report was published in Aug. 1907, declared that the chasm between the native and white races had been broadening for years and that the efforts of the administration to reconcile the Bantus to the changed conditions and to convert them into an element of strength had been ineffective. Among other proposals for a more liberal and sympathetic native policy the commission urged the creation of a native advisory board entrusted with very wide powers. "Personal rule," they declared, "supplies the keynote of successful native control"—a statement amply borne out by the influence over the natives exercised by Sir T. Shepstone. The unrest in Zululand delayed action being taken on the commission's report. But in 1909 an act was passed which placed native affairs in the hands of four district commissioners, gave to the minister for native affairs direct executive authority and created an advisory council for native affairs on which non-official members had seats.

Concurrently with the efforts to reorganize their native policy the colony also endeavoured to deal with the Asiatic question. The rapid growth of the Indian population from about 1890 caused much disquiet among the majority of the white inhabitants, who viewed with especial anxiety the activities of the "free," i.e., unindentured Indians. Several acts had already been passed imposing restrictions upon Indians, and in 1908 a strong commission was appointed to inquire into the whole subject. This commission reported in 1909, its general conclusion being that in the interests of Natal the importation of indentured Indian labour should not be discontinued. For sugar, tea and wattle growing, farming, coal-mining and other industries indentured Indian labour appeared to be essential. Nothing further was done in Natal up to the establishment of the Union of South Africa, when all questions specially or differentially affecting Asiatics were withdrawn from the competence of the provincial authorities.

Union and After.—Not long after the conclusion of the war of 1899–1902 the close commercial relations between the Transvaal and Natal led to suggestions for a union of the two colonies, but these suggestions were not seriously entertained. The federation or union of all the colonies was a different and more reasonable measure; and this matter was formally reopened by the Cape ministry in 1906. The movement for union rapidly gained strength, and a national convention to consider the matter met in Durban in Oct. 1908. In Natal, especially among the older colonists, who feared that in a united South Africa Natal interests would be overborne, the proposals for union were met with suspicion and opposition, and the Natal ministry felt bound to submit the question to the people. A referendum act was passed in April 1909, and in June following the electors by 11,121 votes to 3,701 decided to join the Union. (See SOUTH AFRICA, UNION OF.) Meanwhile it was agreed by the Cape, Transvaal and Natal Governments that, subject to Natal entering the Union, its share of the Rand import trade should be 25% before and 30% after the establishment of the Union. Previously Natal had only 22½% of the traffic, and this agreement led to a revival in trade. The closing months of Natal's existence as a separate colony thus found her peaceful and prosperous. On the establishment of the Union on May 31, 1910, Natal entered it as an original province, Sir Ralph Moore, the premier, becoming a member of the first Union cabinet.

The change from the status of a self-governing colony to a province of the Union affected Natal politically more closely than any other province, since in it alone were the great majority of the white inhabitants of British descent. The firm attachment of Natalians to the British connection continued an unchanging factor in the South African situation. Provincial administration was, however, largely carried on upon non-party lines. An exception

occurred in 1927 when not a single candidate opposed to the inclusion of the Union Jack in the national flag of the Union was returned to the provincial council. About 70% of the total expenditure of the council is on education. Sir George Plowman, who had filled the office of administrator with great ability since 1918 was succeeded as administrator in 1928 by H. Gordon Watson.

The Indian Problem.—Of the 161,339 British Indians in the Union in 1921, no fewer than 141,336 lived in Natal. Besides labourers, there were many Indians engaged in professions and commerce. White South Africans in general opposed the further increase of Asiatics in the Union; while, in 1911, the Indian Government, long dissatisfied with the attitude of Natal to Indians, prohibited the recruitment of indentured coolies. The Indians both in Natal and the Transvaal complained of many grievances, and their cause was championed by M. K. Gandhi, then resident in South Africa. Arising out of the agitation, riots and disturbances occurred in Natal in 1913. In 1914 the Union Government passed legislation intended to prevent Indian immigration into South Africa and to prevent Asiatics already in the Union leaving the province in which they lived. The Smuts-Gandhi agreement of that year was designed to guard the vested interests of Indians already in the Union. The attitude of the white inhabitants of Natal was shown by the borough ordinance passed by the provincial council in Jan. 1924, debarring Indians in future from acquiring the municipal franchise. This ordinance was held up by the Union Government for consideration, but in Dec. 1924, assent to its operation was given. The parliamentary franchise was, with few exceptions, already confined to whites. In 1925 there were 38,547 parliamentary electors, of whom only 24 were Indian. In 1927 an agreement on the Indian question was reached by the Union Government and the Government of India, which led to an amelioration of the condition of Indians in Natal.

NATAL, a city and port of Brazil and capital of the State of Rio Grande do Norte, on the right bank of the Rio Potengi, or Rio Grande do Norte, about 2 m. above its mouth. The population of the municipality in 1920 was 30,696. Natal is the starting-point of the railway which extends on down the coast to Pernambuco and Maceió, and is a port of call for coastwise steamers, which usually anchor outside the bar. The harbour has been improved and the Brazilian government uses the port as a naval depot. The only industry of note is the manufacture of cotton, but the exports (chiefly sugar and cotton) are large. Natal was founded in 1597 as a military post to check an illicit trade in Brazil-wood. In 1633 it was occupied by the Dutch, who remained until 1654. It became the capital of a province in 1820.

NATCHEZ, a noted tribe of lower Mississippi river, near the present city of Natchez, who after massacring the French in their territory in 1729, were defeated by them, the remnants taking refuge with the Chickasaw, and later with the Creek and Cherokee. Allied in general culture to the Muskogian tribes (*q.v.*), they had developed a sun worship with a perpetual fire in a temple, and a caste division into "suns," nobles, honoured men and commoners or "stinkards." This system was matrilineal and exogamic, "suns" marrying "stinkard" wives and having honoured children, whereas "sun" women married "stinkard" husbands and had "sun" children. The head "sun" had power of life and death over all others, and was followed in death by his spouses, attendants and voluntary victims. The origin of these anomalous customs is not clear. See J. R. Swanton, *Bur. Am. Ethn. Bull.* 43 (1911).

NATCHEZ, a city of Mississippi, U.S.A., on the Mississippi river, near the southern boundary of the State; county seat of

Adams county. It is on Federal highway 61, and is served by the Illinois Central, the Mississippi Central and the Missouri Pacific railways, ferries to Vidalia, La., river steamers and barges. Construction of a bridge across the Mississippi, to carry both highway and railway traffic, has been authorized. Pop. (1920) 12,608 (54% negroes); estimated locally at 16,000 in 1928. Except for the docks and river-front warehouses, the city is built on bluffs 200 ft. above the river. There are three parks overlooking the river, and in the heart of the city is the Confederate Memorial park. On a neighbouring bluff is a National cemetery. Jefferson Military college (chartered 1802), one of the oldest schools in the south-west, is 6 m. from the city. In the neighbourhood are many beautiful estates, including "Gloster," the home of Winthrop Sargent, first governor of the territory; "Monmouth," the seat of Gen. Quitman; "Somerset" and "Oakland," long in the Chotard family; and "The Briars," girlhood home of Varina Howell, the wife of Jefferson Davis. There are Indian mounds in the vicinity. Natchez is a trade centre and an important shipping point for cotton and other agricultural products. It has box factories, cottonseed-oil and cotton textile mills, fruit-cake and coffee-roasting factories, with a total output in 1925 valued at \$3,312,856. Natural gas is piped in from the Louisiana fields.

The Natchez Indians were living here when La Salle and De Tonty visited them in 1662, and when Le Moyne de Bienville in 1716 built a fort, which he named Rosalie, for the duchess of Pontchartrain. In 1764 Ft. Rosalie passed from the French to the English and was renamed Panmure; in 1779 it was turned over to the Spaniards; in 1798 it was occupied by U.S. troops. The city was chartered in 1803. It was the capital of Mississippi from 1798-1802 and from 1817-21. The first cottonseed-oil mill was built here in 1834. On May 7, 1840, a large part of the city was destroyed by a tornado. At the opening of the Civil War Natchez was a centre of culture and wealth, and an important port of call throughout the golden days of river traffic. It surrendered to Union forces during the Vicksburg campaigns.

NATHANAEEL, THE APOSTLE. See APOSTLE.

NATICK, a town of Middlesex county, Massachusetts, U.S.A., 18 m. W.S.W. of Boston, at the S.E. end of Cochituate lake. It is served by the Boston and Albany railroad. Pop. (1925) 12,871 (State census). Its varied factory products were valued at \$3,826,547 in 1925. Natick is the Indian name ("our land" or "hilly land") of the tract (originally part of Dedham) granted to John Eliot in 1650 for the "praying" Indians. Until 1719 the Indians held the land in common, and for some years the community was governed (in accordance with Exodus xviii.) by "rulers of tens," "rulers of fifties" and "rulers of hundreds." The town owns a copy of Eliot's Indian Bible. An Eliot monument was erected in 1847 near the site of the Indian church. Natick was incorporated as a town in 1781.

NATIONAL ANTHEMS. In *Europe* the chief national anthems are: *The United Kingdom*, "God Save the King" (see below); *France*, "The Marseillaise" (q.v.) by Rouget de Lisle; *Germany*, formerly "Heil dir im Siegeskranz," words by Balthazar Gerhard Schumacher, music of "God Save the King"; but since the Revolution, "Lied der Deutschen," (Deutschland, Deutschland, Deutschland über Alles, über Alles in der Welt); *Switzerland*, "Ruft du, mein Vaterland," music "God Save the King"; *Italy*, "The Royal March" by G. Gabbetti; *Austria*, formerly "Gott erhalte unsern Kaiser," words by L. L. Haschke, music by Haydn, since the World War "Oesterreichische Bundeshymne," words by Karl Renner, music by Wilhelm Kienzl; *Hungary*, "Isten áld meg a Magyarot"; *Belgium*, "La Brabançonne," by F. Campenhout; *Holland*, "Wien Nieerlansch"; *Denmark*, "Heil dir, dem Liebeden," words by H. Harries, music of "God Save the King," and "King Kristian stod ved højen mast," words by Ewald, music by Hartman; *Sweden*, "Ur Svenska hjertans"; *Russia*, formerly "Bozhe Zaria chraný," words by J. J. Canas, music by D. Jenko; since the Revolution, the "Internationale," words by E. Pottier; *Rumania*, "Traeasca Regale," words by V. Alexandri, music by E. A. Hübsch; *Spain*, "Himno de Riego," music by Herta; *Norway*, "Ja Vi elsker Dette Landet" (Yes, We Love This Country); *Czechoslovakia*, "Kde Domor Muj" (Where Is My Native Land?)

which is the Czech anthem; the Slovak population sings "Nad Tatrou Se Blyska" (Lightning above the Mountains); *Bulgaria*, "Shoumi Maritza" (The Bubbling Maritza); *Greece*, "Ethnicos Ymnos" (The People's Hymn, which has been beautifully translated into English by Rudyard Kipling); *Serbia*, "Srpska Himna," (The Serbian Hymn); *Turkey*, "Istiklal Marsi" (The March of Independence); *China*, "The Song of the Kuomintang"; *Japan*, "Kimigayo" (In the Reign of our Emperor), the tune of which Sullivan adapted in the prelude to the light opera *The Mikado*; *Canada*, "The Maple Leaf Forever." In the *United States*, "The Star Spangled Banner" (1814; words by F. S. Key, music by J. S. Smith) and "Hail Columbia" (1798; words by Joseph Hopkinson, music by Fyles) share the duties of a national anthem, while the tune of "God Save the King" is sung to words beginning "My Country, 'Tis of Thee," by Samuel F. Smith (1808-1895).

The most celebrated of all national anthems is the English "God Save the King," which is said to have been first sung as his own composition by Henry Carey in 1740; a version was assigned by W. Chappell (*Popular Music*) to the *Harmonia Anglicana* of 1742 or 1743, but no copy exists and this is now doubted. Words and music were printed in the *Gentleman's Magazine* for October 1745. There has been much controversy as to the authorship, which is complicated by the fact that earlier forms of the air and the words are recorded. Such are an "Ayre" of 1619, attributed to John Bull, who has long been credited with the origin of the anthem; the Scottish carol, "Remember, O thou man," in Ravenscroft's *Melismata*, 1611; the ballad "Franklin is fled away" (printed 1669; and a piece in Purcell's *Choice Collection for the Harpsichord* (1696). The words or part of them are also found in various forms from the 16th century.

The question was discussed in Richard Clarke's *Account of the National Anthem* (1822), and was reinvestigated by W. H. Cummings in his *God save the King* (1902). Carey and Bull, in the general opinion of musical historians, divide the credit; but in his *Minstrelsy of England* (1901) Frank Kidson introduced a new claimant, James Oswald, a Scotsman who settled in London in 1742, and worked for John Simpson, the publisher of the early copies of "God Save the King," and who became chamber composer to George III. What appears to be certain is that 1745 is the earliest date assignable to the substantial national anthem as we know it, and that both words and music had been evolved out of earlier forms. Bull's is the earliest form of the air; Carey's claim to the remodelling of the anthem rests on an unauthoritative tradition; and, on general probabilities, Oswald is a strong candidate. The tune was adopted by Germany and by Denmark before the end of the 18th century.

NATIONAL BANK OF COMMERCE IN NEW YORK

was established in 1839 at a time when the Federal charter of the Bank of the United States had expired and the need in New York of an institution of large capital to finance the current undertakings of manufacturers and merchants was felt by many business men.

The original capital of the bank was \$5,000,000, the full amount of which however was not paid in until 1852. Increased to \$10,000,000 in 1856, the capital was raised to \$25,000,000 following consolidations with the National Union Bank in 1900 and the Western National Bank in 1903. The bank's growth is indicated by the following figures:

Date	Capital paid in	Surplus and undivided profits	Loans, discounts and investments	Total deposits
May 13, 1839	\$ 1,199,280	\$ 4,211	\$ 1,270,505	\$ 831,392
May 8, 1865	10,000,000	2,836,563	15,925,186	12,615,071
June 29, 1900	10,000,000	7,029,203	60,959,379	65,423,628
June 30, 1910	25,000,000	15,803,079	138,840,979	181,854,933
June 30, 1920	25,000,000	31,533,152	329,868,021	370,448,229
June 30, 1928	25,000,000	46,295,159	505,408,375	571,473,934

In both its domestic and foreign business the bank's attitude has been one of co-operation with other institutions through the development of strong correspondent relations. It maintains its own representatives in London, Paris and Berlin and in 1919 it organized the French American Banking Corporation in conjunc-

tion with the First National Bank of Boston and the Comptoir National d'Escompte de Paris. A Trust Department was established in 1923. (S. E. W.)

NATIONAL BANK OF EGYPT. The National Bank of Egypt was founded by Sir Ernest Cassel in collaboration with a financial group in Egypt. It was established in 1898 by Khedivial Decree and was given the sole right of Note Issue. The head office is at Cairo and there are many branches in the rest of Egypt and the Sudan. There is also a London office at 6 and 7, King William Street, E.C. 4. Besides the board in Egypt, there is a London Committee. The first governor was Sir Elwin Palmer, who was succeeded by Sir F. Rowlett.

The principal object of the bank, outside ordinary banking functions, was to act as bankers to the Egyptian Government and to provide a satisfactory paper currency. It had originally a department for making small loans to the *fellaheen* on security of mortgage, but this grew to such dimensions that it was handed over to a separate institution, the Agricultural Bank of Egypt.

Before the war, the note issue was based half on gold, half on securities approved by the Government. It attained a total of some £3,000,000 in 1913. On the outbreak of the World War, the notes were made a forced legal tender, and in October 1916, British Treasury bills deposited at the Bank of England were authorized as security in place of gold. The total issue ran to over £70,000,000 in 1919, and is now over £30,000,000.

The capital of the National Bank of Egypt is now £3,000,000 fully paid, with reserves of £2,775,000. (S. C. P.)

NATIONAL BETTER BUSINESS BUREAU, INC., organized in 1912 as the National Vigilance Committee of the Associated Advertising Clubs of the World, "to promote honesty, truthfulness and reliability in the sale of merchandise, securities and services, discourage fraudulent and deceptive methods in business and thereby to increase public confidence in advertising, salesmanship and business generally."

The better business bureau movement is participated in by 10,000 industrial, financial and mercantile institutions. Its financial support comes from all fields. Besides the 42 better business bureaux the National bureau is aided by securities commissioners, chambers of commerce, prosecuting officials, newspapers, banks, brokers and investment houses and, for special mining and oil problems, State mining officials, oil inspectors and geologists.

The work of the bureau is divided into three operating groups: financial, merchandise and publicity. The financial section's work is educational, corrective and punitive. It is educational in that it aims to conserve the savings of investors through the distribution of facts relative to financial offerings; it is corrective in that it investigates practices which are contrary to sound business procedure and adjusts them by moral suasion or if necessary, publicity, while in the punitive field it concentrates upon the development of facts regarding unsound projects, co-operating closely with State and Federal officials in the enforcement of existing laws. The bureau's merchandise work centres upon co-operation with 26 specific industries to correct misleading advertising and trade practices by formulating standards of fair play for buyer and seller. Investigation and exposure of merchandise frauds supplement this programme, the chief value of which lies in the help it offers to legitimate interests in business to organize, thus isolating the dishonest practitioner.

NATIONAL BISCUIT COMPANY, THE, a United States biscuit manufacturing company, was incorporated on Feb. 3, 1898, under the laws of New Jersey with a charter valid for 99 years. This company was the result of the merger of the New York Biscuit company, American Biscuit and Manufacturing company and the United States Baking company, together with a number of smaller concerns. Originally capitalized at \$55,000,000, the authorized capital stock in 1922 was \$85,000,000, of which \$25,000,000 was 7% preferred stock and \$60,000,000 (\$25.00 par value) common stock. There was outstanding as of Jan. 1, 1928, \$24,804,500 preferred stock and \$51,163,000 of common stock. The company was among the first to encourage purchase of its stock by its employees, having put such a plan into effect as early as 1901.

Prior to 1898, biscuit and crackers had been sold in boxes, barrels, crates and other large containers with the resulting liability to staleness before the stock was disposed of to consumers. The new company inaugurated the package for biscuit with its "Uneeda Biscuit." The company now produces more than 400 varieties of biscuit as well as bread and cake manufactured through its subsidiary, the National Bread company, organized to take over this branch of the business. There are 40 cracker bakeries located in 30 cities of the United States, including a bakery in York, Pa., devoted exclusively to the manufacture of pretzels. There is also a cracker bakery in Toronto, Ontario, operated by a subsidiary called "National Biscuit Company (Canada) Limited." National Biscuit company maintains and operates its own machine shops in which it develops and improves mechanical means to perform all the productive operations. Further economy is achieved through ownership of the National Milling company at Toledo, O., where a large portion of the flour used by the company is manufactured, and by the manufacture of box-board and cartons by the company's paper-board mill and carton factory at Marseilles, Ill. The company's general offices are in New York city. (C. A. V.)

NATIONAL BOARD OF FARM ORGANIZATIONS, THE, a board established in the United States in 1917 for the purpose of giving to the various agricultural organizations and cooperative associations of the country a common voice in matters where they have a common interest. It has been influential in connection with much agricultural legislation. Its constituent members in 1929 were: The National Cooperative Milk Producers' Federation, The Farmers' Educational and Cooperative Union of America, The Pennsylvania State Grange, and The Farmers' Equity Union.

NATIONAL CITY BANK OF NEW YORK, THE, was organized under charter from the State of New York on June 16, 1812 as the City Bank, with a paid-in capital of \$800,000, its origin being closely associated with the dissolution of the First Bank of the United States. Samuel Osgood, first U.S. postmaster-general, was its first president. With the passage of the National Banking Act in 1865, the City Bank became a part of the new national system and at that time its name was changed to the National City Bank of New York.

Engaged primarily in the financing of commerce, the growth and development of the institution has kept pace with the expansion of American industry and trade. As late as 1892, 80 years after its organization, its capital stood at 1 million dollars, surplus and undivided profits of scarcely 2½ millions and deposits of but 20 millions. Commencing with the early years of the present century, the growth became more marked. The capital was increased in 1900 from \$1,000,000 to \$10,000,000, and two years later from \$10,000,000 to \$25,000,000, where it stood until 1920 when, with deposits of approximately \$700,000,000, its capital was again increased to \$40,000,000 and its capital structure, including surplus and undivided profits, for the first time exceeded \$100,000,000, with total resources in excess of \$1,000,000,000. In Apr., 1929, the National City Bank with capital at \$100,000,000, surplus and undivided profits of \$111,000,000, deposits of \$1,349,024,386 and total resources of \$1,847,705,548 merged with the Farmers Loan and Trust Co., capital \$10,000,000, surplus and undivided profits of \$23,212,698, deposits of \$170,436,931 and total resources of \$219,050,022, to make an institution with resources exceeding \$2,000,000,000, the largest bank in the western hemisphere and third largest in the world. The name of the larger bank was retained.

With the passage of the Federal Reserve Act, this bank was the first of American institutions to establish foreign branches throughout the world, such branches in 1928 numbering 88 in 22 foreign countries. In 1921, under changes in law which then took place, branch expansion in the city of New York became possible and 28 local branches were established in 1928.

Affiliated with the banks and owned ratably by the shareholders of the bank, is the National City Company, an originating and distributing investment banking organization with a capital structure in excess of \$100,000,000. (C. E. M.)

NATIONAL CONFEDERATION OF EMPLOYERS' ORGANIZATIONS. This institution is the employers' central organization in Great Britain for dealing with general labour questions on behalf of employers as a whole. Its constitution covers all questions arising out of industrial relations, but it does not deal with commercial questions.

Prior to the convening of the National Industrial Conference of Employers and Employed in 1919 by the prime minister, there was no central machinery for joint consultation on the employers' side between the employers' federations in the individual industries dealing with labour questions, and the confederation was set up to meet the need. The confederation's membership is confined to the central employers' federations dealing with labour questions in the various individual industries, and the federations within its membership cover industries employing over seven million workpeople.

In its national sphere, the confederation is officially recognized by the Government and by the various Government departments which deal with labour questions (e.g., Ministry of Labour, Home Office, Ministry of Health, etc.). The subjects it deals with are varied, including factory law, unemployment and health insurance, workmen's compensation, hours and conditions of work and trade boards. The confederation also submits evidence for employers before royal commissions and Government committees. In its international sphere, the confederation is recognized by the Government as the industrial organization "most representative of employers" under Article 389 of the Treaty of Versailles. In that capacity it nominates the British employers' delegate to attend the annual International Labour Conferences held under the treaty, and its representative is a member of the governing body of the International Labour Office.

NATIONAL CONVENTION, THE. In the United States the National Convention is the political agency of the major parties which nominates the party candidates for president and vice president, adopts the platform, and performs other party functions. The first national nominating convention in the United States was that of the old Federalist Party which met in New York in Sept., 1812, and endorsed for the presidency De Witt Clinton, the candidate of the peace Republicans. This gathering, however, had no influence on the displacement of the congressional nominating caucus by the national convention. The Anti-Masonic Party met in national convention at Baltimore in Sept., 1831. This convention was composed of 112 delegates for 13 States and adopted "An Address to the People of the United States." The National Republican or Whig Party followed with a convention at Baltimore in December of the same year, with each State entitled to a delegation the size of the electoral vote of the State. A system of State and local correspondence committees was authorized. The Democratic Party held its first national convention in Baltimore in May, 1832, for the purpose of nominating Martin Van Buren for vice president, as the running mate to President Jackson. Since then the national convention has been the recognized method of selecting presidential and vice presidential candidates.

While the number of delegates in the early conventions fluctuated, ordinarily each State was limited to a vote equal to its electoral college strength. Eventually twice as many delegates were sent as there were electors, and finally each delegate was given an entire vote. The Democratic Party now allows twice as many delegates to each State as there are presidential electors with six each to Alaska, the Canal Zone, the District of Columbia, Hawaii, the Philippine islands and Porto Rico and two to the Virgin islands, making a total of 1,100 for the convention of 1928.

The Republicans formerly had a similar representation, but this was reduced in 1913 in order to lessen the influence of delegates from the normally Democratic States of the South, and again changed in 1921. The Republicans now allow four delegates from each State at large, with two additional where a representative in Congress is chosen from the State at large. In addition, the Republicans allow three more from each State at large where a majority of the electoral vote of the State went to the party at the preceding presidential election. Each congressional district is allowed one delegate, and an additional delegate from each dis-

trict casting 10,000 votes for the Republican electoral ticket at the last presidential election or the same number of votes for the party candidate for representative in Congress at the last congressional election. Two delegates each are chosen by Alaska, the District of Columbia, Hawaii, the Philippine islands and Porto Rico. There were 1,089 delegates in the Republican convention of 1928. There are as many alternates as delegates who vote in the absence of the delegates.

In the December or January preceding the convention, the national committee of each party meets in Washington and issues the call for the next national convention. At this time the allotment of delegates is made and the State committees are instructed as to how they are to be chosen. A convention city also is selected, giving consideration to auditorium facilities, hotel accommodations, financial donations and political benefits. The convention delegates are elected by State and district conventions and under the terms of presidential primary laws, according to State statutes and party rules and by State party committees. They are either instructed as to presidential preference or are sent uninstructed; some are instructed as to vice president. Prior to the convening of the convention, usually in June or July, the national committee meets to make final arrangements for the convention. A temporary roll of convention delegates is made and a temporary organization is suggested for the convention.

The chairman of the national committee calls the convention together and the first question is on temporary organization. After temporary organization has been effected, the temporary chairman makes a "key-note" speech sounding the campaign issues. Then the committees on rules and procedure, credentials, permanent organization, and platform and resolutions are appointed, each delegation having one member on each committee.

After the adoption of rules and the report on credentials, a permanent organization is effected. The permanent chairman also speaks in outline of the campaign issues. The convention then proceeds to nominate candidates and adopt a platform. Nominations for president are made by calling the roll of delegations. Seconding speeches often are made. A majority vote is necessary to nominate in the Republican convention while the Democrats require two-thirds. After the candidate for president is nominated, a choice for vice president is made along the same procedure. A platform is adopted either before, during or after the nominations. Committees on notification of the two candidates are named and the convention adjourns after authorizing the national committee to fill any vacancies on the ticket.

The national committee, composed of a man and woman from each State and territory, assumes office upon adjournment of the convention, the members being selected by the delegations or by State conventions or primaries if so authorized by State statutes or party rules or by State conventions.

Bruce, *American Parties and Politics* (1927); Stuart Lewis, *Party Principles and Practical Politics* (1928), and *Readings in Party Principles and Practical Politics* (S. L.).

NATIONAL COUNCIL OF EVANGELICAL FREE CHURCHES, a voluntary association of British Nonconformist churches for co-operation in religious, social and civil work. It was the outcome of a unifying tendency displayed during the latter part of the 19th century. About 1890 the proposal that there should be a Nonconformist Church Congress analogous to the Anglican Church Congress was seriously considered, and the first was held in Manchester on the 7th of November 1892. In the following year it was resolved that the basis of representation should be neither personal (as in the Anglican Church Congress) nor denominational, but territorial; and the name of the organization was changed from Congress to National Council as soon as the assembly ceased to be a fortuitous concourse of atoms, and consisted of duly appointed representatives from the local councils of every part of England. The local councils consist of representatives of the Congregational and Baptist Churches, the Methodist Churches, the Presbyterian Church of England, the Free Episcopal Churches, the Society of Friends, and such other Evan-

gical Churches as the National Council may at any time admit. The constitution states the following as the objects of the National Council: To facilitate fraternal intercourse and co-operation among the Evangelical Free Churches; to assist in the organization of local councils; to encourage devotional fellowship and mutual counsel concerning the spiritual life and religious activities of the Churches; to advocate the New Testament doctrine of the Church, and to defend the rights of the associated Churches; to promote the application of the law of Christ in every relation of human life. Although the objects of the Free Church councils are thus in their nature and spirit religious rather than political, there are occasions on which action is taken on great national affairs. The movement differs essentially from the Evangelical Alliance, inasmuch as its unit is not an individual, private Christian, but a definitely organized and visible Church. The essential doctrine of the movement is a particular doctrine of churchmanship which regards the Lord Jesus Christ as the sole and Divine Head of every branch of the Holy Catholic Church throughout the world.

The Report of the National Free Church Council is published at the headquarters of the organization, the Memorial Hall, Farringdon Street, London E. C. The Report for 1927-28 shows that England, Wales and the Channel Islands have been covered with a network of Councils, each of which elects its representatives to the annual gathering. The movement has spread to Australia, New Zealand, South Africa, Jamaica, the United States of America and India.

NATIONAL DEBT, the financial obligations of a State, as distinct from the obligations of its individual members. The very use of the word debt, however, makes it advisable to indicate a few important distinctions between national and individual indebtedness. In the case of the debt of an individual, there is invariably an obligation to repay at some period the whole of the principal and in the meantime to maintain a certain rate of interest. In the case of national debts there is great variation in the form of the obligation. More frequently there obtains the same rule for ultimate repayment of the principal; indeed, there is often an obligation to repay at a certain date a larger sum than has been originally raised. Such loans usually take the form of the borrowing State paying a comparatively small rate of interest, the loan itself being issued at a discount, e.g., a country instead of borrowing a loan for £100,000,000 in 5%’s at par, i.e., at the price of £100 for £100 of stock, might issue a loan in the shape of 4%’s at 80, covenanting to repay at a certain date at par. In such an instance what is called the “flat” yield to the investor, i.e., the actual rate of interest received each year on each £100 invested might be the same as in the case of the 5% loan at par, namely 5%. Ultimately, however, the investor would in reality have obtained a rather better yield, because at the date of the maturity of the loan he would receive £100 for every £80 invested. Correspondingly, the borrowing country might have incurred a greater cost in its debt service, because while the actual interest due each year would be smaller, the amounts to be set aside for ultimate extinction of the loan would be greater.

Various Forms of Borrowing.—A State may resort to a form of borrowing which is impossible to the private individual by making its loans in what is known as lottery form, the lender, which is another name for the applicant for the loan, accepting some low rate of interest in return for the chance of winning a financial prize by a system of drawings of numbers. Such loans have been both numerous and popular in France and in some other continental countries where patriotism and cupidity combined have often resulted in the raising of very large amounts in lottery loans. A State enjoying good credit can with little difficulty borrow enormous sums without any undertaking at all to repay the principal at a particular date. The explanation is to be found in two further points which also demonstrate the difference between State and private borrowing. It will easily be seen that the better the credit of the borrower the more ready will be the lender to advance for a lengthy period, and because the credit of the State is usually the highest credit of all there is seldom difficulty in procuring loans for an almost interminable

period. A further explanation, however, is to be found in the fact that the loans themselves form what is known as marketable securities, that is to say, the holder of them is able at any time to convert his holding quickly into cash by selling it to some other individual. Moreover, in the United Kingdom and in some other countries it is customary for all long-dated Government stocks to be trustee securities, which means that they are in the class in which trustees are specially authorized to invest trust money. This again in its turn means that trustees usually seek for stocks which are not redeemable at some early date. Therefore, in the case of the British Government it has been quite customary for many hundreds of millions to be raised on terms making the stocks practically irredeemable. The form in the prospectus is usually to say that the stock will be redeemable on and after a certain date at the option of the State, which means, of course, that the Government may, or may not, redeem after that date, according to its own convenience. It is interesting, however, to note that the possibilities of even the best States borrowing for an indefinite period may vary according to circumstances. No better illustration of this can be furnished than in certain events in the history of the British national debt. Thus for many years previous to about 1894, British consols, which formed this class of perpetual debt, were so popular that even when the rate of interest was as low as 2½%, the stock rose in the year 1894 to over 114. That remarkable price was due to the great prosperity of the State and the magnificent credit enjoyed by the British Government, and also to the fact that money market conditions produced a temporary famine in high-class investment stocks, which gave to consols a fictitious value. Then came a combination of circumstances which exerted a very different influence. Under the Goschen conversion (1888), consols, which then bore 3% interest, were converted into stock carrying 2½% until 1903, and 2½% thereafter. When the year 1903 arrived, holders realized, as they had not done in advance, the lower yield of their holdings, and at that particular time other circumstances, among which the Boer War was one, conspired to bring down all investment stocks, including consols, so that even before the World War Britain’s premier stock had fallen to about 71. (The lowest point ever touched by consols was 47½ in the year 1798.) The fictitious character of the high price of 1894 should, of course, have been realized at the time but, as a matter of fact, the plunge downwards in the market price of so sound a stock gave a shock to confidence in irredeemable securities, and when borrowing in the Boer War became necessary, and still more when colossal sums had to be raised in the World War, it was practically impossible to raise loans which did not carry with them a fixed date of redemption. Once, again, however, in the year 1928, when not only was confidence returning, but high-class investment securities were becoming scarce, the irredeemable form of stock again began to be popular, so that in that year the most representative British Government stocks were the 3½% conversion loan and the new 4% consols, in both of which the date of redemption was optional to the Government.

Converting into Lower Interest.—A further feature of national, as distinct from individual debts, is to be found in the manner in which a State is frequently able by means of a rise in its general credit to make terms with its creditors in a way which, if not impossible, is at all events seldom practised by the individual. A State, for example, may in times of stress or emergency, have borrowed a large amount in a 5% form, the loans running for anything from 25 years upwards. Long before the time of redemption arrives, however, the State may have become so prosperous that its credit is really on a 4% or 3½% basis. It is, therefore, in a position to raise fresh money on, say a 3½% basis, repaying the old loan and making a big saving in the annual interest charge. Moreover, the State when it issued its, say, 50 year loan, would have been careful to protect itself by retaining the option to repay at some earlier date, if desired. Therefore, when such conditions arise, the State is in a position to issue a kind of ultimatum to its lenders offering to convert the old loan into perhaps a 3½% issue, failing the acceptance of which repayment takes place. Simultaneously with such offer of conversion,

new subscribers to the $3\frac{1}{2}\%$ loan are usually approached, with the result that under skilful guidance, the 5% debt, long before the final date of repayment, becomes changed into a security carrying a lower rate of interest. Finally, another vital distinction between national and individual debts will certainly be found in the fact that whereas debts between private citizens are recoverable by legal process, such process is seldom enforceable against the State, although it is perfectly true that a State may suffer in its credit in the same way as an individual and can even become bankrupt.

Size of Debts.—Although exceptions might be cited, it may be said broadly that the smaller the national debt in proportion to the resources and the population, the sounder is the position of the national finances, and the higher the standing of the national credit. Considering the question of national debt, quite apart from the special exigencies of War requirements, it can be said that national debts may be necessary in the case of a new country to develop its resources and instances such as Australia and Argentina might be cited where a growth in national debts and in developments of the country's resources and in national prosperity has proceeded *pari passu*. That may be true without lessening the fact that an excessive national debt may bring disaster. Especially when a State is developing its resources on external loans, that is loans raised in other countries, the adverse effect upon its foreign exchange of the large remittances abroad, to meet the service of the debt, may react unfavourably upon the prosperity of the country itself. In that respect, however, much will depend upon whether the borrowing State is rich in resources of an exportable character.

Origin of National Debts.—The origin of the national debts of countries varies considerably and while wars invariably occasion heavy State borrowing some of the newer countries have borrowed—usually externally—to develop their natural resources. Such loans are generally of a reproductive character and so long as the interest rate is not unduly high, or unduly large in proportion to the population, they may often be said to have strengthened the economic position of the borrowing country, though it is well that the annual service of the loan should contain what is known as a sinking or amortisation fund, that is a fund designed to re-pay the loan within a given period of years. Loans raised for war purposes on the other hand, however, necessary for preserving the very existence of a nation, are not of the reproductive order, the proceeds being paid away in powder and shot, and the service of the loans usually acts as a drag upon the borrowing country for many a year. Moreover, war loans usually have the additional drawback of having been raised upon usurious terms, and the borrowing nation generally makes the loans short-dated, in the hope of being able to fund them during the more prosperous times of peace. As an instance of countries which have raised large loans not for war, but for the purpose of self-development, Australia, Canada, Argentina and Brazil might be cited, while older countries such as Great Britain, France and Germany can trace most of their national debts to war and even the United States debts have been largely based on the same cause, although just previous to the World War, the United States had well nigh repaid the whole of her national debt and with the exception of China, had almost the smallest per capita debt in the world.

Forms of Debts.—The internal part of the national debt of a country can usually again be sub-divided into funded, short term and floating debt. Normally the greater part of any national debt of any magnitude such as that of Great Britain for example, is funded or (*see CONSOLS*) is in stock virtually irredeemable other than at the option of the State. In the case of a great increase in debt due to a war, however, it is not unusual to find a great part of the debt in short-dated form and even in floating obligations. The former term generally applies to debt where maturity dates range roughly from anything between five and thirty years, while floating debt is usually applicable to bonds of not more than 3 years' duration, Treasury bills of a few months' duration or to ways and means advances. (*See FLOATING DEBT.*)

Internal and External Debts.—The national debt of a coun-

try can usually be divided into internal and external debts. A moment's thought will show that large external, even more than internal, debt, may be a handicap to a State. If a country has a large internal debt, it may mean that much money has been expended either in war or in unproductive enterprise and that by reason of high taxation to pay the interest, industrial progress is hampered. Still the money represented by the interest remains, as it were, in the family, the payments constituting a transfer from one pocket to another. In the case of an external debt, however, whatever advantages may have accrued from the original employment of the sum borrowed—and if the cause has been a great war, the advantage other than political is seldom of an enduring kind—there remains during the lifetime of the loan a large annual payment to the creditor country which may prove a serious embarrassment to the debtor owing to the effect on the exchange between the two countries. In old-established countries, such as Great Britain, external indebtedness was unknown to the present generation until the World War, when considerable debts to foreign countries were incurred. However, in the case of Great Britain most of these have been repaid, with the exception of the large debt of about £900,000,000 to the United States. In newer countries, however, external debt often constitutes an outstanding feature, the older and wealthier countries having financed the development of their natural resources of the new areas, thereby creating conditions of prosperity enabling the borrowing country to meet the annual interest and sinking funds. Properly conceived such loans are an instance of capital creating new and real wealth. Not infrequently, however, such borrowing proceeds too rapidly and a country although rich in resources is unable for a time to meet its debt charges. Speaking generally, it should be the aim of a country to raise its loan requirements as far as possible internally, even if a slightly higher rate of interest has to be paid.

Debt v. Taxation.—A fruitful subject of discussion among economists with regard to public debt is the extent to which even in emergency the State should resort to borrowing, instead of applying increased taxation, though obviously in times of great emergency, such as war, there must be a limit to taxation pure and simple, for if applied beyond the immediate resources of the tax-payer, a credit in some form or another is inevitable; indeed experience shows that whether a State borrows extensively or over-taxes the community, an expansion in banking credits usually follows. Moreover it has often been urged that a public debt affords a convenient form of investment, especially to those who desire full security for their investment, rather than a high rate of interest. A good case can be made out for the profitable return of monies spent on military and naval defence, such monies being largely in the nature of insurance premiums, and because they add to the feeling of general security, may be said to contribute directly to industrial and financial activities and prosperity in the countries responsible for such expenditure. Save only in the rarest cases however, such expenditure should be met out of revenue, the expenditure being not only of a recurring character, but one where payment out of capital would often lead to profligate and unprofitable outlay.

Danger of Peace Time Borrowing.—Apart from war, or other grave emergencies, a well-organized State ought to have within itself the means of meeting all its ordinary expenses, otherwise the State is in danger of imperilling its credit and moreover making it difficult to borrow on favourable terms when the hour of crisis comes. To some slight extent this was even noticeable in the case of Great Britain at the outbreak of the World War. Not that the credit of Britain at that moment was other than high when compared with that of other nations, but owing to the fact that for some years previously there had been prodigal outlays for social requirements, involving high taxation. British credit as expressed in the price of consols had declined to a level which was not merely distressing to holders of that security, but was a matter of disturbance to bankers and economists, who affirmed that in the event of any sudden crisis arising, the results might be serious. Moreover, in the years immediately preceding the World War, Finance Ministers in Great Britain

had been less rigid with regard to the application of realized securities to debt redemption, and that in its turn had adversely affected consols. Accordingly as noted in another paragraph, Great Britain had to raise her first long-dated war loan in 3½% at the then low price of 95

Capital Assets.—In arriving at the total national liabilities of a country, it is necessary to turn to the statement of assets which is usually presented separately. The total is not usually deducted from the national debt, but it has nevertheless to be borne in mind. In the case of countries where undertakings such as railways and harbours are owned by the State and are revenue producing, such assets constitute a very important item in the national balance sheet and it is not infrequent to find that when such countries are raising external loans, great emphasis is laid upon these assets as an offset to the national debt. In the case of Great Britain a conservative policy is adopted and, in the national debt return of 1927, the total estimated assets are given as only £115,850,000, some of the principal items being the value of Suez Canal shares (owned by the Government) and advances to the unemployment fund. If, however, to these assets were added the liabilities of foreign countries, a total of over £2,000,000,000 would have to be added, including loans from France and Russia. Similarly, as pointed out elsewhere, the United States against its greatly increased internal debt has to set enormous sums due from Great Britain and her Allies in the World War. In the sense, therefore, of these cross currents of war indebtedness, this form of assets constituted an important item in the national balance sheets at the beginning of the year 1928.

BRITISH NATIONAL DEBT

That the national debt of Great Britain is of comparatively recent date is seen from the fact that at the time of the advent of William III. to the throne the total debt was only about £85,000 borrowed on tallies in anticipation of duties on French linens. The increase of debt during his reign was considerable, while the American War of 1775-1786 added about £120,100,000 and the great French wars lasting through the years 1793-1815 added a further £604,000,000 and in 1817 the British national debt reached its highest point for many years, the funded and unfunded debts together making up a total of £848,000,000. From that time a gradual diminution occurred as the result of a steady application of sinking funds and by 1894, and previous to the Boer War, the amount had been reduced to about £635,000,000. During the period of the Boer War, there was a further considerable addition to the national debt and although substantial repayments had been effected previous to the outbreak of the World War, the total deadweight debt at the beginning of 1914 was about £650,000,000. During the World War, the debt went up by leaps and bounds, not only because of the direct cost of the conflict to Great Britain, but because also of the extent to which she financed the cost of the war to her Allies and especially France and Russia. Two years after the conclusion of the war the maximum total of the British war debt was reached, the amount being about £7,830,000,000 but even at the beginning of 1928 the total deadweight debt was about £7,527,000,000. The greater part of this debt was internal, but about £1,100,000,000 was on account of war indebtedness to other countries, chiefly the United States of America. Included in the unfunded debt at the beginning of 1928 was an item of £362,000,000 representing national savings certificates repayable virtually on demand. Strangely enough this is not sectionized in the official Treasury statements as floating debt, though it would certainly appear to come under that category. The origin of this particular form of debt goes back to the period of the World War when war savings certificates were sold on the basis of 15/6d for £1 certificates redeemable at £1 five years hence, the amount to be held by any one holder being restricted to £500. After the war, the issue of certificates upon somewhat less favourable terms was continued, but the name was changed to national savings certificates. Of the national debt of Great Britain no less than £6,900,000,000 is directly the result of the World War and striking evidence is furnished not only of the cost of a great war but of the years of financial disturbance following, by the fact

that ten years after the conclusion of peace only a comparatively small part of the total debt had been funded. At one time in 1919 the floating debt, as expressed in Treasury bills and ways and means advances (short term loans from Government departments or the Bank of England) was no less than £1,338,000,000 and the greater part of the reduction effected in the debt in the following decade took the form of the cancellation of floating debt. At the beginning of the fiscal year 1928, the actual floating debt had been reduced to £716,000,000. During the years 1920-28 inclusive something over £500,000,000 in sinking fund monies was applied to debt redemption in various forms and the explanation of why so small a reduction was accomplished in what is known as the total deadweight debt was due to the fact that many of the conversion operations were effected in lower interest yielding stocks, but offered at a discount. A better idea, therefore, of the effect of the redemption of old debt and the funding operations is to be obtained by noting that whereas the annual service on the British debt apart from sinking funds for 1920-1 was about £342,000,000 the amount required for 1928 was about £304,000,000.

The Recent Growth of British Debt.—Previous to the World War, the national debt of Great Britain passed through many phases and was the subject of many conversion schemes, the last and most notable being the Goschen conversion scheme of 1888 already referred to. These phases and conversion operations, however, fade into insignificance when compared with the additions to, and changes in, the national debt, which occurred during the years of the World War, and the years immediately following. The first increase in the national debt after the outbreak of war assumed the form of large issues of Treasury bills, and these were destined to rise to a maximum level of about £1,300,000,000. The first long-dated loan was created during the latter part of 1914, and consisted of a 3½ per cent war loan for £350,000,000. It was offered at the price of 95 per cent and at the time of issue the yield was regarded as fairly high for a British government stock. Much of it, however, was believed to have been taken up by the Bank of England, and it was found later that greater effort and more attractive terms were necessary to raise the huge sums required for the war. In the same (fiscal) year, short-term Exchequer bonds for £50,000,000 were placed, while the issues in the next year included a 4½ per cent war loan for £900,000,000. The operation, however, including some large conversions of old consols and outstanding annuities, and a part of the 3½ per cent war loan issued in the previous year. In the year 1916, the issue of war savings certificates commenced, which were destined to add more than £300,000,000 to the national debt. The largest single loan operation, however, during the war was that effected in 1917, when the 5 per cent war loan was created to the amount of £2,067,218,744. Of that total, cash subscriptions represented £836,454,260, the rest representing conversions of other loans. This loan which was destined to be the largest individual stock in the national debt, was not however a funding operation, the loan being definitely redeemable in 1947, the Government retaining the right to repay it in 1929 and thereafter. Its distinctive feature was the non-deduction at the source of income tax from the half-yearly interest. In that same year, a 4 per cent war loan to the amount of £52,000,000 was created, of which, however, only £22,000,000 was cash subscriptions, the rest representing conversion operations. In the same year, Exchequer bonds to the amount of £417,000,000 were created, and war certificate sales totalled over £100,000,000. Throughout the years of the World War, and up to and including the year 1920, the new sinking fund was entirely suspended. In 1918, the final year of the World War, national war bonds were sold to the amount of over £640,000,000 and Exchequer bonds for smaller amounts were placed. In that year, however, much of the borrowing was to repay Treasury bills. In 1919, although the war was concluded, war expenditure continued, and short-term national war bonds, carrying with them certain conversion rights, were issued to the amount of £1,045,000,000.

The Peak Year.—The year 1920 marked the zenith of Britain's national debt, and although many of the loans raised during that year were in the nature of conversion operations, a great deal of

new money was raised and as in some of the previous loans, new features had to be introduced to ensure a ready absorption. Owing to the high rate of income tax, which touched 6/- in the £., one Government loan took the form of 4 per cent stock, tax-free, while in the case of yet another loan privileges were given to make payment for death duties with the bonds reckoned at their par value. Again, in 1920, 4 per cent Victory bonds were issued at the price of 85, having the right to be redeemed at par in a series of drawings each year and also carrying the right to be tendered for death duties. Thus it will be seen that although Great Britain did not resort to any forced loans in spite of the great strain of the war, unusual inducements were attached to many of the war loans. Moreover, in addition to the loans raised internally, considerable borrowing was effected in the United States. This borrowing took the form during the earlier years of the war of raising from American nationals, various amounts, ranging up to the equivalent of about £150,000,000. These loans were raised before America came into the World War. Following upon that event, the United States Government gave credit to the British Government for goods and services supplied, and this indebtedness subsequently resolved itself into a liability of over £900,000,000, which was finally funded on terms involving the ultimate repayment over a period of some sixty-two years, dating therefrom. In addition, Great Britain borrowed temporarily certain sums from some of her overseas dominions, and from some foreign countries, but with the exceptions about to be mentioned, all such debts have now been repaid. At the beginning of 1928-29 the British Government recognized loans from certain Allied Governments as outstanding, the total being £135,700,000. These totals, however, were offset by much greater indebtedness to Great Britain, the indebtedness of Russia to Great Britain being £887,335,000; that of France £705,588,000; Italy £270,000,000; Rumania £31,000,000; Portugal £24,000,000 and various other debtors about £60,000,000. In addition Great Britain was owed by her overseas dominions about £123,000,000. At the end of the fiscal year 1927-28 the amount of the British funded debt of £1,232,000,000, was made up as follows:—2½ per cent Consols, £276,206,164; 2½ per cent's £2,399,679; 2½ per cent's £21,120,357; 3½ per cent Conversion Loan £739,935,758; 4 per cent Consols £166,384,125; Debt to Banks of England and Ireland £13,645,869; Terminable annuities £12,242,000. Of the total unfunded debt of £5,287,714,849, the largest item consisted of 5 per cent war stock for £2,088,173,683; Treasury bills for £599,175,000; 4 per cent funding stock and bonds £388,777,644 and national savings certificates £371,823,328.

Dates of Redemption.—A feature of British debt at the beginning of 1928-29 was the large amounts maturing within a comparatively short period. The outstanding item was that of the 5 per cent war loan for £2,172,000,000, the Government having the option to redeem after 1929 and being compelled to redeem by 1947. In spite of the magnitude of the amount, the possibility of early redemption prevented the loan from rising much above 100, although it carried the exceptional attraction of income tax not being deducted at the source, holders returning separately to the authorities particulars of income derived therefrom. Consequently the stock is largely held by small investors, who, if the tax were deducted at the source, would be put to the inconvenience of making special claims for recovery. An interesting development in the case of this loan and of the 4 per cent funding loan (on which no interest is charged to foreign holders) occurred in 1928 when American investors became interested in them and large blocks were purchased on New York account, indeed the buying was so pronounced as to occasion a considerable rise in the stocks on the London stock exchange and to occasion sympathetic movement in other descriptions. Apart from the 5 per cent war loan, other maturing debts to be dealt with between the years 1930 and 1946 amount in the aggregate to a little over £800,000,000.

Dates of Maturing Debt.—In addition, however, to the debt maturing at fixed dates, Treasury bills outstanding at the beginning of the fiscal year 1928-9 amounted to £527,000,000 and the national savings certificates to £362,375,000. Accompanying his budget for 1928-9, the Chancellor of the Exchequer published the statement on page 141 with regard to the debt posi-

tion on that date.

Debt Redemption and Conversions.—Reference has been made to the famous Goschen conversion scheme of the British debt in 1890, when existing 3%’s were gradually converted, first into 2½%’s, then into 2½%’s. All British debt conversions, however, fade into insignificance compared with the post-war problem of converting the debt arising out of the World War. That problem too was enormously increased not only by the great sums borrowed, but by the high rates of interest paid. At the beginning of the war, the British Government was paying interest on consols at the rate of 2½%, while much of the debt incurred during the war was on a 4%-5% basis. Previous to 1914, the total amount involved in the consolidated fund service yearly was £24,500,000. In his annual budget for 1928-9, the Chancellor of the Exchequer fixed £355,000,000 as the amount to be applied annually to the consolidated debt service, that total including the sinking fund. For some few years previous, the new sinking fund (the new sinking fund as applied to British debt, means the amount set aside at the beginning of each year towards debt service and redemption; what is known as the old sinking fund is the realized surplus at the end of the year, which goes automatically to debt redemption) had been separated and fixed at amounts varying between £40,000,000-£65,000,000 annually, and the change effected in the 1928-9 budget meant the restoration of the old Sir Stafford Northcote sinking fund. Thus with a fixed amount of £355,000,000 applied consistently to the debt service, the amount available each year for actual debt redemption should increase in cumulative fashion owing to debt redemption in the previous year. Indeed, the Chancellor of the Exchequer in restoring this system, which had been in abeyance since the World War, estimated that in the absence of any further addition to the British debt, the system should provide for its complete extinction in fifty years’ time, including the indebtedness to the United States. Past experience has shown, however, that these fixed allocations are not always inviolate, Chancellors of the Exchequer having on more than one occasion appropriated realized surpluses for the year and applied them to purposes other than debt redemption. Moreover, the effectiveness of the fixed fund in the case of a State possessing a heavy floating debt, such as that represented by the £500,000,000 of British Treasury bills, is very much at the mercy of the course of money rates in calculating the amount required each year for interest charges. A difference of 1% either way in the value of money affects the interest charged on Treasury bills alone to the extent of £5,000,000. Consequently, there is the possibility of the operative force of the sinking fund being materially weakened should money rates be particularly high in the course of any one year. Moreover, such conversions as were effected in British debt during the years following the war were not sufficiently favourable to the State to occasion very much lightening of the annual interest charge, while owing to the number of conversions which were effected on the basis of loans issued at a discount the actual diminution in deadweight debt was trifling, when compared with the amount of sinking fund money used. The chief conversion operations have consisted in the conversion of Treasury bills into short-dated bonds, and of bills and bonds into the 4% funding loan, the 3½% conversion loan, and the 4% consolidated loan, the amounts of which are set out in the foregoing table. The explanation of the growth in the 5% war loan from the original total mentioned earlier is explained not by further borrowing, but by various short-term bonds having been given the right of conversion into the 5% war loan. The problem of conversions of the British debt is a vital one for the taxpayer, as constituting the chief hope of relief from oppressive taxation. Whether as a result of failure to economize, or of conditions beyond the power of the State,* such as unfavourable money markets, the inability of Great Britain to convert its debt more readily, and more profitably, has contrasted sharply with the United States, where as a combined result of economy and prosperity, debt redemption and conversion has been on a greater scale. During the post-war period, however, Great Britain has had the difficult task of combining her problem of improving national finance with that of restoring the gold standard. This

Debt Maturing Year by Year (Approximate Totals)

N.B.—The amounts shown for National War Bonds are the Nominal Totals, and do not include premiums. National Savings Certificates are shown at issue price, exclusive of accrued interest. External debt is shown at par of exchange. Loans marked * are being repaid by specific statutory Sinking Funds, included in the provision for New Sinking Fund.

latter task successfully accomplished, while adding to the credit of the country, probably involved higher money rates than might otherwise have been necessary, and that in its turn increased the expenditure represented by the annual interest on the national debt, and was also unfavourable to debt conversions.

Committee on British Debt.—In 1923 a committee was appointed on national debt and taxation, presided over by Lord Colwyn, and its report was published in 1927. The majority of that committee recommended that steps should be taken to increase the sinking fund to £75,000,000 a year. They hoped that with the aid of additional repayments of loans by the Governments of Great Britain's Allies, reductions in the interest charge from conversions and redemptions, and possibly expanding revenue, such an amount should be quite practicable within a brief period. The committee was also strong in its recommendations that Government conversion loans should not be issued at a discount, but the advice was disregarded. The Colwyn committee also deprecated any other system than that of definitely revealed and fixed sinking funds. They stated that in their opinion "there was no possible device which could absolutely ensure the continuance of debt redemption, if the Government of the day decided on a contrary policy." Their recommendations as regards the enlargement of the sinking fund as a whole were strengthened by the fact that the sinking fund provisions, ear-marked for specific loans, themselves encroached very considerably upon the total amount available for debt redemption as a whole.

Contingent Liabilities.—Arising out of post-war conditions in Great Britain, a new form of liability was incorporated by the

State in connection with various undertakings mostly of a local character, where money although not raised directly by the State, carried with it State guarantees. The circumstances responsible were generally those connected with the dearth of money, which made it difficult for industrial concerns to raise new capital on terms calculated to make the undertaking a paying proposition. Accordingly, and for a short period, when it was shown that the capital required was for the purpose of providing employment, which would not otherwise be provided, the State gave certain guarantees. The total amount involved was not large, being probably within the limit of about £100,000,000 but the point is one to be regarded as coming within the sphere, if not of British debt, of British liabilities, and moreover constituting a special feature arising out of the financial and social problems following upon the World War.

Debt of British Dominions.—Although the debts of the United Kingdom are self-contained, and there is no kind of liability with regard to the indebtedness of overseas dominions, the sentimental connection between them is close and especially so in recent years, when there is an increasing tendency in Great Britain to speak of empire as well as of the national finances. If, therefore, the British debt were to be added to debts of the various overseas dominions, the position at the beginning of 1928 comes out approximately as follows:—

United Kingdom	£7,527,000,000
Irish Free State	£ 17,300,000
Canada	£ 562,000,000
Australia (Commonwealth)	£ 461,000,000

New Zealand	£ 246,000,000
India	£ 721,000,000
South Africa	£ 221,956,000

These figures show that the total increase in the debt of the British Empire for the past quarter of a century is about £8,560,000,000, the growth being as remarkable in the case of the overseas dominions as in the case of Great Britain itself. For the most part, the growth in the Canadian and Australian indebtedness may be connected with the World War, but expenditure on the development of the resources of new countries has also added a considerable part, especially in the case of Australia.

A reference to the table of debts will show that the growth of debt per head in the Australian dominions has been remarkable and has occasioned considerable concern to the chief lending country—Great Britain. Moreover, while largely connected with development of the country's resources, the borrowing has also been stimulated by somewhat extravagant expenditure and Australia might be quoted as a classic instance of the problem of how far extensive borrowing, even for productive purposes, may tend to go ahead of the capacity of the population to bear the strain of the increased debt charge. Not the least interesting feature of the external debt of British dominions during the post-war period has been the tendency to borrow fairly large amounts in the United States, both Canada and Australia having raised large loans there.

(A. W. K.)

Statistics of National Debts in Great Britain, British Dominions, and the United States

Country	Population (in thousands)	Total debt (in thousands)	Per capita debt	Total annual charge (in thousands)	Per capita charge
United Kingdom	44,738	(1) £7,587,000	£168	£355,000* (1928-9)	£7.9

THE UNITED STATES

When Alexander Hamilton (*q.v.*) became the first secretary of the U.S. Treasury in 1789, one of the major problems confronting him was the preparation of a statement of the National debt, and a plan for its settlement. This was the subject of his *Report on Public Credit* submitted on Jan. 9, 1790. The foreign debt, almost all French, incurred during the Revolution, including principal and accumulated interest, was placed

at \$11,710,000. It had been contracted under certain precise conditions which allowed of no disagreement in the way it was to be paid. The domestic debt was more difficult to determine since it consisted of a variety of credit obligations issued at different times under varying terms of contract. Hamilton estimated the principal at \$27,383,000 and accrued interest at \$13,030,000. These credit obligations had passed current in the country as monetary medium and had depreciated in value. The question arose as how they should be repaid, and Hamilton reached the conclusion that the present holders should be paid full value. Against much popular ill feeling Hamilton's plan was adopted. The third question, concerning the matter of State debts which totalled \$18,271,786, was whether the Federal Government should assume these debts or not. Hamilton favoured assumption on the theory that it would contribute to a more orderly, stable and satisfactory arrangement of national finances and also contribute to national unity. The Southern States, whose debts were low, objected to the plan, and Hamilton was able to carry it through only by a political bargain which granted to the Southern States the removal of the national capital from Philadelphia to a territory to be set off from Virginia and Maryland, the District of Columbia. The Funding Act of Aug. 4, 1790, which provided for three loans to take up the three different classes of indebtedness, at once stabilized the finances of the new nation.

If the debt was not reduced so much as it was hoped in the following decade, it was not the fault of the administration so much as it was due to unexpected events. In 1801 the total debt stood at \$83,000,000, a slight increase. However, during the able administration of Gallatin, the debt was cut to \$45,200,000 (1812), in spite of the added Louisiana Purchase debt, which was paid off in five years. The last of the foreign debt was paid in 1809. The excellent record was halted by the War of 1812, the expenses of which raised the debt to a new height in 1816 of \$127,334,000. Much was paid off during the years 1816-17, but bad years following greatly entangled the finances. Disadvantageous long-term loans were resorted to, which could not be taken up by the surplus accruing in the better years following 1822. So favourable were the finances after 1825, however, that in spite of the handicap of inelastic loans, the entire debt was paid off by 1835, and the Treasury began to accumulate a surplus which proved almost more embarrassing than a debt.

The Mexican War created a net indebtedness of \$49,000,000. All of the bonds were easily placed at par and some at a premium, which may be contrasted with the financing of the War of 1812, when loans in stock were sold with difficulty even at a discount. Also the loan was subscribed to in specie for the first time since the foundation of the Government.

When Salmon P. Chase was appointed secretary of the Treasury by President Lincoln at the beginning of the Civil War, the national debt was \$74,985,000, of which \$18,000,000 had been incurred since the beginning of the secession movement. The demands of the Civil War called for financial operations on a scale which made all former Treasury records seem insignificant. Unceasing drain on credit and reverses in the field made the fiscal year of 1862-63 the darkest in the nation's history. Bonds did not sell at home even at a discount and found no market abroad. Temporary loans and the issue of notes were resorted to. After the battles of Gettysburg and Vicksburg in 1863 matters took a brighter turn and Chase's third report in 1864 was optimistic. The public debt on Sept. 1, 1865 at the end of the war, stood at \$2,758,000,000, the highest in the nation's history until the World War. Less than one-half of this was funded. For the first few years after the war a portion of the available revenue was devoted to a partial contraction of the currency by retiring greenbacks, but in 1870 and 1871 funding acts were passed which authorized the issuing of \$1,800,000,000 worth of bonds at 4%, 4½% and 5%, redeemable in from 10-30 years, to care for the major part of the debt. The funding acts shaped the character of the debt for the next quarter century. By saying that the bonds were redeemable in "coin" and not in gold, a troublesome silver controversy was later raised. An attempt was made to place some of the bonds abroad, but the Franco-Prussian War and other con-

ditions prevented much success. In general there has always been much opposition in the United States to borrowing abroad by the National Government, and it was never seriously attempted except under the stress of the Civil War. The 30 year period for the major share of the bonds under the Funding Act was too long. A surplus appeared in the Treasury in 1882 which could otherwise have been applied to their retirement. Long before the bonds were due the Government could borrow money at 2½%. Despite the fact that the bonds were selling at a premium and that the effect was naturally to raise their quotations, different secretaries of the Treasury bought in the open market all that could be purchased. Thus the indebtedness was reduced from \$1,996,000,000 in 1879 to \$891,000,000 in 1890, a remarkable achievement at that time.

The Spanish-American War again raised the debt, but the Funding Act of 1900 arranged for it together with other old loans to be refunded into 30 year 2% gold bonds. A small cash premium was paid to induce holders to make the exchange. From 1902 to 1913 there was little change in the debt total, retirements being balanced by increases due to the construction of the Panama canal. In 1913 the debt stood at \$1,028,600,000, nearly three-fourths of which bore interest at the rate of 2%.

During the World War years the national debt reached a new peak. For the fiscal years ending June 30, 1917, 1918 and 1919, the respective additions to the debt were \$902,353,000, \$9,015,646,000 and \$13,555,021,000. On June 30, 1919, the grand total stood at \$25,482,034,000. Practically all the war-time indebtedness was in the form of bonds held by U.S. citizens. The Treasury Department immediately after the war began the reduction of the total. Its success was such that the annual decrease averaged almost \$900,000,000. By June 30, 1928, the national debt had been lowered to \$17,526,219,000. Concerning this matter, the report issued by Secretary of the Treasury Mellon dated Nov. 19, 1927, is particularly interesting. (For details of the recent period see UNITED STATES: Finance.) (X.)

OTHER NATIONAL DEBTS

Although the increase in the national debts of the world during the last quarter of a century has been mainly due to the great World War, and therefore affects primarily the debts of the belligerent countries, there has nevertheless been a rise in the indebtedness of almost every country throughout the world. This, of course, to some extent is normal, and usually proceeds *pari passu* with the growth of population. Some idea, however, of the manner in which the costs of the war hit the belligerent countries may be gathered from the great change which has taken place in the debts *per capita* of the various nations compared with the beginning of the present century. In 1920 the French debt was easily the largest, but in the liability per head France came fourth in the list, while the United Kingdom occupied the third position in a list of 25 countries as regards total debt, and the eleventh as regards liability per head. In 1928, however, Great Britain easily led the way with the largest debt in the world of £7,527,000,000, representing a *per capita* liability of £168, while the total annual charges give a *per capita* charge of nearly £7.10s. This compares with a total debt at the beginning of this century of £628,979,000, representing only £15.7s.6d. per head and an annual charge per head of only 11s.4d. In noting, however, the fact that the French debt now falls greatly below the British debt, allowance has to be made for the fact that the franc has been devaluated. At the beginning of 1928 the French franc was not definitely stabilized, but it had stood for a long period at the rate of 124 francs to the £, and it is on that basis that francs in the table have been converted into sterling. It will be seen, therefore, that but for this process of conversion, the French debt would have stood at more like £13,000,000,000, or considerably ahead of all the other debts of the world, including that of Great Britain.

Even more striking, of course, is the enormous increase in the *per capita* liability of some of the British dominions with small populations, their indebtedness having been heavily increased as the result of the share taken by them during the World War and the subsequent resumption of expenditure on development. Thus, the *per capita* debt of New Zealand works out to the extraordinarily heavy amount of £171, and even in Canada the debt *per*

STATISTICS OF NATIONAL DEBTS

§Includes mks. 25,000,000,000, capital value of reparations liabilities, also mks. 2,000,000,000, annual charge for 1927-8.

¶Includes all "Treasury" expenditure.

||Internal debt only.

capita is nearly £60.

In the case of many of the foreign countries, and notably in the case of Russia, post-war conditions are still so chaotic that only a bare estimate of debt can be given, and in the case of Germany and some other countries, comparison with the beginning of the century is almost impossible by reason of the fact that, while on the one hand new debt has been increased by borrowings, the old debt has been practically wiped out or greatly reduced owing to depreciated currencies. As regards Germany, there has also to be added to the ordinary debt vast liabilities under the head of reparations (see REPARATIONS). Comparison of the debts of countries like Austria and Czechoslovakia with the figures at the beginning of the century is impossible owing to the territorial changes resulting from the Treaty of Versailles.

Asiatic Countries.—As regards the Asiatic countries, there has been a heavy increase in the debts both of China and Japan. At the beginning of the century, the *per capita* debt of China was about 3/- and the *per capita* annual charge only about 2d. At the beginning of 1928, both politics and finance in China were in a chaotic state, while the very fact of the great variation in the estimates of population makes it impossible to give really reliable figures with regard to proportion of debt to population. There was no doubt, however, as to the very large expansion of the debt

and, so far as may be judged, the *per capita* debt had risen to about 10/- and the *per capita* charge of the annual service to about 9d. The Japanese debt too, which at the beginning of 1900 amounted to the equivalent of only £53,000,000, had risen in 1928 to about £500,000,000 and the *per capita* charge of the annual service to about 9½d. against 1½d. In the case both of China and Japan the growth into debt has been largely the result of wars.

South America.—In the South American countries, an interesting feature to note is the fact that although the Argentina debt has grown since the beginning of this century from £103,000,000 to £182,400,000, the actual debt per head has fallen from £23.12.0. to just under £18,—the reason, of course, being the great increase in the population. In fact, Argentina furnishes a striking instance of a country where growth in the debt has been accompanied by a more than proportionate increase in the total wealth.

NATIONAL DEPOSIT FRIENDLY SOCIETY: see FRIENDLY SOCIETIES.

NATIONAL DIVIDEND. National Income has been defined as "the aggregate money expression of those goods produced, and services performed, by the inhabitants of a country, which are, as a fact, generally exchanged for money." The terms National Income and National Dividend are convertible, only the latter is more significant "when we are looking at the national income in the character of the new sources of enjoyment that are available for distribution" (Marshall), i.e., the flow or fund, before it is assigned to individuals. This may be looked at in two sharply contrasted ways: "the flow *produced* during a year, or, the flow *consumed*." Dr. Marshall said "The labour and capital of the country, acting on its natural resources, produce annually a certain net aggregate of commodities, material and immaterial, including services of all kinds. This is the true net annual income or revenue of the country, or the national dividend." (Of course, services rendered by people to themselves, that they might have received from others and paid for, are not counted, otherwise the money valuation so essential for practical purposes would become difficult and vague.) Some writers (e.g., Professor Fisher) have excluded savings as not being income, unequivocally claiming to "identify the National Dividend with those services and those only, that enter directly into consumption." But it is best to distinguish this and avoid confusion, as the "national income of consumable goods." Various corrections of gross money income of individuals taken in the aggregate are necessary to prevent double counting, e.g., War loan interest paid out of income tax on incomes which have not been reduced (by the amount of the tax) in aggregation. If this were not done, the greater the War loan indebtedness the greater would be the amount of the national income, *without any change in the physical and usable incomes of goods and services.* (See also WEALTH, NATIONAL.)

NATIONAL FINANCE: see FINANCE.

NATIONAL GEOGRAPHIC SOCIETY, an American scientific society founded in Washington in 1888, "for the increase and diffusion of geographic knowledge." Its membership in 1929 was 1,200,000, of whom 77,000 resided in 88 other countries. In the field of research it has sent expeditions to many parts of the world, some wholly financed by it, others in collaboration with other institutions and organizations. The expeditions it has sent out to study the processes of volcanism and seismology, including studies at Mont Pelée, Messina, Mt. Katmai and the Pavlof area brought new light on these earth processes and resulted in the discovery of the Valley of Ten Thousand Smokes in Alaska, the greatest pre-geyser land known, which has been established as a national monument by proclamation of the U.S. president. In tracing the ancient civilizations of the New World the society, in conjunction with Yale university, unearthed the ancient Inca retreat, Machu Picchu, in Peru, and in a series of eight expeditions unearthed the even more ancient community of Pueblo Bonito, N.M., and laid the foundations for the co-ordination of the tree-ring calendar with our own and the establishment thereof of an American chronology antedating the discovery of America by many centuries. In supporting active polar research the society aided Admiral Peary in all his Arctic work, sent the MacMillan-Byrd expedition to the Arctic (1925) and helped to finance the Byrd Antarctic expedition of 1928-29. In aiding solar research the society made the grants that provided the observatory and maintenance of the Brukkaros station of the Smithsonian Institution. In the field of spreading geographic knowledge the society publishes the *National Geographic Magazine*, which every member receives, issues a bulletin service for the daily press of the world, furnishes the schools of the United States with material for current-event geography and pictorial geography text in loose-leaf form. It also issues scientific monographs and publishes a widely distributed series of maps. (G. GR.)

NATIONAL GUARD (United States), that part of the militia which is organized and trained as land troops (a) subject to the jurisdiction of the governors of the various States and territories for use in local emergencies and (b) when in the service of the United States, a part of the United States army under the chief command of the President.

History.—The Constitution of the United States, recognizing the need for a well regulated militia, set forth general principles for its organization and government. The Union was obliged to protect all States thereof against invasion and, under certain conditions, against domestic violence. Various acts of Congress from 1792 onwards were passed, but none provided an effective militia. In 1903 the "Dick Bill" was enacted. This law distinguished between the whole body of citizens capable of bearing arms and subject to military service but untrained, and the organized militia comprising the naval militia and the land militia, the latter to be known as the National Guard. It was to have the same organization, armament and discipline as the regular army and to be instructed and inspected by officers of the regular establishment. Although this compromise was a vast improvement, it failed to satisfy the demands of the Constitution or the needs of the nation. The supplementary Act of May 27, 1908, gave the President power to draft the National Guard into the service of the United States, either within or without the borders of the country, without the formality or delay of volunteering either by organizations or by individuals.

The National Defence Act.—The outbreak of war in Europe in 1914 led finally to a demand for preparedness which culminated in the National Defence Act of June 20, 1916. This was amended in the light of war experience by the Act of June 4, 1920. These laws provided for the first time a comprehensive and definite military system such as was contemplated by the founders of the American Union, and adapted to modern needs by such interpretations and Federal grants as to permit the establishment of uniformity throughout the country.

The National Guard is recruited by voluntary enlistment of men between the ages of 18 and 45 for a period of three years and subsequent re-enlistments for either one or three years. The

strength originally contemplated by law was 435,000, but in view of the national policies the War Department does not expect that it will exceed 250,000. The strength in 1927 was 181,142. The organization in time of war is that of the regular army, modified for peace time needs. The commanding general of a brigade or division and, in time of war, the chief of staff and one assistant chief of staff of a division may be regular army officers. Under these laws the only troops permitted to the States are National Guard troops and these can be organized only by consent of the United States. Units are allocated to the States by the President upon recommendations made by a board of the general staff composed in equal parts of regular officers and National Guard officers holding reserve commissions in the U.S. army. States which receive Federal aid are forbidden to disband units or to reduce them beyond a fixed strength, and this aid is given only when the units reach a prescribed degree of efficiency determined by inspections. Administration is conducted by the militia bureau of the War Department, the chief of which must be an active or a former member of the National Guard. The country is divided into nine corps areas each embracing several States and supporting, in addition to regular and reserve formations, two infantry divisions of the National Guard and such coast artillery, corps, army and G.H.Q. reserve troops as may be prescribed. On the staff of the commanding general of each corps area is an officer for National Guard affairs.

Within each State the governor is commander in chief of the National Guard thereof and administers it through an adjutant general and a State staff. Divisional boundaries overlap State lines. Despite the apparent complication of this arrangement it works smoothly because it is to the interest of both State and Federal Governments that it should. Arms and equipment are the same as for the regular army and, together with other stores, animals, forage and the expenses of Federal officers on duty with the National Guard, are provided by the Union. The States supply armouries and other facilities, sometimes including additional pay for allowances. The troops are paid by the Federal Government at the rate of $\frac{3}{8}$ the initial or base pay per month for every armoury drill up to a maximum of 60 drills per annum; and during field training (about 15 days per year), pay, subsistence and transportation are at the same rate as for the regular establishment. Courts-martial can sentence to forfeiture of pay and assess fines or levy other punishments, and their processes must be carried out by the civil authorities. They have the power to issue subpoenas and warrants of arrest and to compel the attendance of witnesses.

Personnel and Training.—The quality of the personnel is high, but the annual turnover is large. Among subaltern officers it reaches 26% per annum. Training is therefore limited to basic drill. Physical standards are maintained by annual examinations. All ranks take their duty seriously. About 50% of all officers in 1927 held commissions as reserve officers, and ultimately this will be required of all, as examinations for appointment and promotion in both are according to the same standard, which among senior officers is high. Subalterns come from the ranks, from the reserve officers' training corps in colleges and universities (conducted by officers of the regular army); and sometimes from the citizens' military training camps. In 1927 officers were distributed as follows:—

Major Generals of the line	14
Brigadier Generals of the line	53
Brigadier Generals, adjutants general	19
State staff corps and departments	461
Staffs of division	371
Staffs of brigades	207
Officers of units less than a brigade	10,828
Total	12,013

Encampments or manoeuvres may be held separately or in conjunction with regular troops. Officers and enlisted men may be attached to regular units for field training. Instructors from the regular establishment are detailed for duty with the National Guard on the basis of one to a battalion or equivalent unit, which requires a total of 476 officers in addition to 589 non-commis-

sioned instructors. Special courses are given for both officers and enlisted men at service schools, and from 1920 to 1927 a total of 1,702 officers attended such courses at branch schools, the command and general staff school and the army war college. Such provisions have raised the standards of personnel and instruction. Training has improved rapidly in recent years and the National Guard is developing a strong *esprit de corps*.

Present State.—In 1927 no less than 17 States called out their National Guard in local emergencies, such as the Mississippi floods and the Florida hurricane, and these crises have proved these troops to be a reliable force, and have earned it the warm support of the States. Although proficiency varies with local conditions some National Guard units with a short period of combined training would make first class combat troops.

When drafted into the Federal service the National Guard becomes an integral part of the United States army, subject in all respects to the same rules and regulations. It serves for the duration of the emergency, after which it reverts to State control. As an indication of the increased reliance placed upon this force as an asset in the national defence, one may compare the appropriation of \$1,000,000 for 1900 with the following:

Year	Appropriation	Strength
1910	\$ 6,450,150	37,210
1920	13,194,791	56,090

In 1927 the Chief of the Militia Bureau reported: "It is evidently the intent of Congress, and all War Department plans and policies bear it out, that the National Guard is to be used as first line troops subject to call at the same time as the regular army."

A. W. Bradbury, U.S. Army. (J. M. Sc.)

NATIONAL INSURANCE: HEALTH. Any satisfactory scheme of national health insurance should have two main objects, (1) to secure for the insured any medical attendance that he may require at any time, and (2) to compensate him by money payments for the loss of wages when compelled to cease work through sickness. Until late in the 19th century there was little or no recognition in any country of any duty of the State to concern itself with the making of provision against sickness amongst its workers. In many countries some provision was made independently of the State by the workers themselves through mutual provident associations, but only part of the field was covered by this means, and the less thrifty section of the community, who were most in need of protection, were rarely included. The position in many working-class households was, therefore, that when sickness fell upon the breadwinner, involving ordinarily not only cessation of his wages, but also the extra cost of doctor's bills, as soon as any small savings had been exhausted there was no alternative but recourse to the poor law. In 1883 a compulsory scheme of insurance was introduced in Germany and this was extended in 1889 to cover permanent incapacity. The example of Germany was followed by Austria in 1888 and by Hungary in 1891. About the beginning of the 20th century public opinion in most European countries began to crystallize in favour of some organized provision to meet the contingency of sickness amongst the workers, and in one country after another schemes based on the German model of compulsory insurance were brought into operation.

I. GREAT BRITAIN

The scheme of national health insurance in Great Britain was founded on the National Insurance Act, 1911, which was brought into operation on July 15, 1912. The scheme is on a compulsory and contributory basis, the cost being shared between the workers, the employers and the State. The persons who are required to be

insured comprise roughly the whole wage-earning community over the age of 16, with the exception of non-manual workers remunerated at a rate exceeding £250 a year. There are, however, a few exceptions, of which the most important are persons employed under the Crown, a local authority or a statutory company who, by the terms of their employment, are entitled to provision during sickness at least equivalent to that provided under the act. In addition to these excepted persons who are completely outside the national scheme of health insurance, persons who would normally be compulsorily insured may claim exemption if they can prove that they have a pension or unearned income of at least £26 a year, or that they are mainly dependent for their livelihood on someone else or on some non-insurable occupation. The employers of these exempt persons are, however, required to pay the employer's share of the contribution. Persons who are compulsorily insured by virtue of their employment are known as employed contributors. The scheme also allows any person (other than a married woman) who has been insured for at least two years as an employed contributor and has paid at least 104 weekly contributions to continue in insurance as a voluntary contributor, if he so elects, on ceasing to be employed. A married woman may not herself be insured as a voluntary contributor but where an uninsured man marries an insured woman who has paid at least 104 contributions he is allowed to become a voluntary contributor. The total number of insured persons at the end of 1927 was about 16,000,000.

Contributions.—The weekly rate of contribution has, from the year 1926, been 9d. for men and 8½d. for women, of which 4½d. is payable by the employer. The employer is required to pay the whole contribution in the first instance, but may recover the portion for which he is not himself liable by deduction from the wages of the worker. In the case of a voluntary contributor the whole contribution is payable by the contributor himself. The contribution of the State towards the cost of the scheme takes the form of the payment of a definite proportion of the cost of all benefits and of their administration. Since 1926 the proportion payable by the State has been one-seventh in the case of men and one-fifth in the case of women insured persons.

The weekly contributions are at a flat rate irrespective of the age at which persons first become insured. The rates are fixed so as to cover the actuarial cost of the benefits in the case of persons entering insurance at the age of 16. For persons first becoming insured at higher ages the contributions at the flat rate would not in themselves be sufficient to cover the actuarial cost of the benefits and the shortage is made good by the creation of book credits called reserve values. These book credits are gradually converted into cash through the operation of a sinking fund derived from small deductions from all weekly contributions over a period of years. This system of reserve values, taken in conjunction with the payment by the State of a proportion of the cost of benefits and administration, is equivalent in its effect to the provision by the State of the reserves required to enable the benefits to be given to all insured persons at a flat rate of contribution irrespective of age at entry into insurance.

Benefits.—The benefits to which the insured persons become entitled in return for their contributions are—

(1) *Medical Benefit*, i.e., free medical attendance and treatment and any necessary medicines. The medical attendance is limited to such as is within the competence of an average general practitioner. A person becomes entitled to medical benefit immediately on becoming insured and in general remains entitled throughout his insurance.

(2) *Sickness Benefit*, which consists of weekly cash payments to the insured person when rendered incapable of work by illness, the standard rates being 15s.0d. a week for men and 12s.0d. a week for women. Sickness benefit is payable from the fourth day of incapacity and may continue for a maximum period of 26 weeks. A person does not become entitled to sickness benefit until he has been insured for 26 weeks and has paid 26 weekly contributions. Benefit is then payable at the reduced rate of 9s.0d. a week for men and 7s.6d. a week for women. When 104 weeks of insurance have been completed and 104 contributions paid, benefit

becomes payable at the full standard rates.

(3) *Disablement Benefit*, i.e., weekly payments at a reduced rate when, and so long as, incapacity continues after the title to sickness benefit has been exhausted. The normal rate of disablement benefit is 7s.6d. a week both for men and women. The qualifying conditions for the receipt of disablement benefit are 104 weeks of insurance and the payment of 104 weekly contributions.

(4) *Maternity Benefit*, i.e., a money payment in the event of the confinement of an insured woman or the wife of an insured man. The standard rate of maternity benefit is £2, and in the case of a married woman who is herself insured, benefit is payable both in respect of her own and her husband's insurance. The qualification for maternity benefit is 42 weeks of insurance and the payment of 42 weekly contributions.

(5) *Additional Benefits*, which may take the form either of an increase in the standard rates of the cash benefits, or of payment towards the cost of various forms of treatment required by the insured persons, such as dental, ophthalmic or convalescent home treatment. These additional benefits differ from the ordinary benefits in that they are only payable by Approved Societies which are found on valuation to have a surplus available for the purpose.

Contributions are payable for every week during the whole or any part of which an insured person is employed. If there has been no employment during a week the insured person falls into arrears and unless these arrears are excused or redeemed by making the appropriate payment within the time allowed, penalties in the form of reduction or suspension of cash benefits will result. From the inception of the scheme arrears have been excused when due to incapacity for work through sickness of which notice has been given, and by the Act of 1928 arrears which can be shown to have been due to genuine unemployment also involve no penalty. In effect, therefore, the present position is that an insured person is credited with a contribution in respect of every week during which he is either employed, sick or genuinely out of work, but if, during any contribution year (July to June) there are any weeks in respect of which no contribution is credited, e.g., weeks of voluntary abstention from work or weeks during which the insured person is engaged in some occupation which is not employment within the meaning of the Act, then unless the arrears for such weeks are redeemed within the period of grace the rates of sickness and disablement benefits are reduced throughout the ensuing calendar year in proportion to the number of arrears outstanding.

The title to sickness and disablement benefits and the liability for the payment of contributions cease on an insured person attaining the age of 65, at which age in the normal case the title to a contributory old age pension accrues.

Where an insured person is rendered incapable of work by an accident or industrial disease in respect of which he is entitled to compensation under the Workmen's Compensation Act or to damages, sickness and disablement benefits are not payable to him unless the weekly value of compensation or damages is less than that of the benefit which would ordinarily have been payable. In this case the difference only is payable by way of benefit.

An employed contributor does not cease to be insured and entitled to benefits immediately on ceasing employment but continues so entitled for a period between 1½ and 2 years at the full rates of benefit, and if he can show that throughout that period he was genuinely unemployed his insurance is continued for a further year, subject, however, to reduced rates of benefit. A person who has been insured for at least 10 years and who becomes unemployed after reaching the age of 60 is allowed to continue in insurance (so long as he remains genuinely unemployed) until he attains the age of 65, and thus his title to a contributory old age pension is safeguarded.

Payment and Collection of Contributions.—The contributions are paid by means of the purchase of special stamps at any post office. The health insurance contribution is paid jointly with the contribution payable under the State scheme of contributory widows', orphans' and old age pensions, by means of a single health insurance and pensions stamp to the amount of the joint contribution. One of these stamps has to be affixed to the

insured person's contribution card in respect of each week of employment, but special arrangements may be made in certain cases for stamping in bulk. It is the duty of every insured person to obtain a contribution card at the beginning of each contribution period and to present the card to his employer to be stamped at the proper times. The contribution period is a period of six months commencing on the first Monday in January and July of each year. If an insured person fails to produce a contribution card to his employer to be stamped at the proper time, the employer is required to stamp an emergency card, which can be obtained at any post office. The money for health insurance received at post offices from the sale of health insurance stamps is paid into a fund known as the National Health Insurance Fund, which (in England) is under the control of the Minister of Health and out of which all the moneys required for the payment of health insurance benefits and the cost of their administration is supplied.

Medical Benefit.—The arrangements for the administration of medical benefit are on a territorial basis and are made through special bodies, known as Insurance Committees, in every county and county borough. These committees are composed, as to a majority, of representatives of the insured persons in the area, the remaining members being representative of doctors or nominated by public authorities. It is the duty of the insurance committee to prepare a panel of all the doctors in the area of the committee who desire to treat insured persons, and any registered medical practitioner has the right to have his name placed upon the panel. The insured person has free choice of the insurance practitioner from whom he is to receive treatment. The insurance practitioner enters into an agreement with the insurance committee, by which he undertakes to provide to all insured persons on his list any medical treatment (within the competence of a general practitioner) which they may require at any time and to prescribe for them such medicines as may be necessary. In return for his services he is paid at the rate (since 1924) of 9s.6d. a year for every insured person on his list. In addition to this capitation payment doctors in rural areas receive a supplementary mileage allowance in respect of additional cost of travelling. The insured person can obtain the medicines prescribed for him by his doctor from any chemist taking part in the service. A further obligation of the insurance practitioner is to supply the insured persons on his list with such medical certificates of incapacity for work as they may require in order to make good their claims to sickness and disablement benefits. The total charge on insurance funds to meet the cost of medical benefit and its administration is limited by the Act to 13s.6d. per insured person per annum.

Cash Benefits.—The cash benefits, *i.e.*, sickness, disablement and maternity benefits, are administered by bodies known as Approved Societies. These bodies are independent self-governing groups of insured persons banded together for the purposes of the national health insurance scheme. They are not ordinarily on a territorial basis but the members generally have some community of interest which may be religious, occupational or social, or may arise out of private insurance with the same society. Any body of persons may make application to the Minister of Health for approval, the only statutory conditions attached being that the body should not be carried on for profit and that it should make rules to the satisfaction of the Minister for the administration of State insurance under which the affairs of the society must be subject to the absolute control of its members. On approval being granted the society becomes entitled to receive the contributions of all insured persons who become members and it undertakes to pay them the cash benefits to which they may become entitled. An insured person is free to select his own approved society and a society may accept or reject any applicant for membership in accordance with its rules. The number of approved societies in Great Britain is about 1,000, and the membership varies from less than 100 to more than 2,000,000. About thirty approved societies are divided into branches, each of which is a separate and autonomous financial unit. The total number of such branches is about 7,000. Ap-

proved societies are of many types, of which the principal are Friendly Societies (either with or without branches), Trade Unions, societies associated with industrial assurance companies, and employers, or works, societies. Every approved society has complete control of its own funds and the members stand to gain or lose as the result of their society's experience and standard of administration. The insured members of a society are required to surrender to the society their stamped contribution cards at the end of each contribution period and the society is credited in the National Health Insurance Fund with the total value of health insurance contributions represented by the stamps on the cards surrendered by all the members of the society. Out of its credit in this fund, with the relative State grant, the society obtains the necessary money for paying all benefits to which the members become entitled, as well as the cost of the society's administration. So far as the amount standing to the credit of a society in the National Health Insurance Fund is more than sufficient to meet the current expenses of the society, the balance becomes available for permanent investment and one-half is paid over to the society itself for investment by the trustees, the other half being transferred to the credit of the society in the investment account and invested by the national debt commissioners.

A small deduction is made from every weekly contribution paid in respect of each member of a society and is allocated to a contingencies fund which is available to meet any deficiency which may be disclosed on the valuation of the society. After each valuation the sum standing to the credit of the contingencies fund is transferred to the benefit fund of the society, and in so far as it is not required to make good any deficiency it becomes available for the provision of benefits. A further protective fund, similarly derived, but augmented by a contribution from the Exchequer, is the Central Fund, which is a single fund common to all societies and is available to meet the balance of any valuation deficiency which cannot be met out of a society's own contingencies fund. The granting of assistance from the central fund is conditional on the deficiency not being due to unsatisfactory administration on the part of the society.

In order to claim sickness or disablement benefit an insured person who has become incapable of work through sickness should at once obtain from his insurance doctor a certificate of incapacity and should forward it to his approved society. Further medical certificates should similarly be obtained and forwarded at intervals (normally weekly) as required. If the society is satisfied that the member is incapable of work and that the necessary qualifying conditions for benefit are satisfied, payment of benefit is made to the member weekly. Similarly a claim for maternity benefit is made by the insured person sending to the society the necessary certificate of confinement. Any dispute between an insured person and his society with reference to a claim for benefit has to be referred to arbitration in accordance with the rules of the society, and a final right of appeal lies to the Minister of Health, whose decision is binding on both parties.

A society which is in doubt as to the incapacity for work of a member claiming benefit, can obtain a second medical opinion on the point by referring the member for examination to one of a body of medical referees known as Regional Medical Officers, appointed by the Minister of Health.

Every approved society is required to keep accounts of its receipts and expenditure under the act and to submit these accounts to audit by auditors appointed by the Treasury. The amount which a society may expend on administration is limited to 4s.6d. per member per annum. Every approved society and branch is subject to a valuation of its assets and liabilities at intervals, usually of five years, by valuers appointed by the Treasury. If on valuation a surplus is disclosed, such part of the surplus as the valuer certifies to be disposable for the purpose is used by the society in providing additional benefits for its members in accordance with a scheme drawn up by the society and sanctioned by the Minister of Health. A scheme of additional benefits ordinarily covers a period of five years. If on valuation a society or branch is found to be in deficiency, recourse must be had first to the society's own contingencies fund, and if that is not sufficient

to make good the deficiency application may be made for a grant from the central fund.

The results of the valuations which have been made show that the finance of national health insurance is on a thoroughly sound basis. At the first valuation, which was made as at Dec. 31, 1918, the great majority of all societies and branches were found to have surpluses, the aggregate amount of which was about £17,000,000. On the second valuation, which was made as at Dec. 31, 1923 (or a year earlier in the case of certain societies) the membership of societies showing surpluses was about 15,000,000, while that of societies with deficiencies was less than 250,000. The aggregate amount of the surpluses exceeded £42,000,000, of which about £15,000,000 was kept in reserve, the balance being devoted to the provision of additional benefits. Many of the societies were thus enabled to make substantial additions to the standard rates of sickness, disablement and maternity benefits, and also to pay the whole or part of the cost of various forms of treatment required by their members and not provided as part of medical benefit. The most popular of these treatment benefits is dental benefit, which is provided for about 75 per cent of the whole insured population, and to which a sum of nearly £3,000,000 a year is devoted. The benefit ordinarily takes the form of the payment by the society of not less than 75 per cent of the cost of any dental treatment obtained by the member and not less than 50 per cent of the cost of any dentures supplied. A scale of charges has been agreed between the approved societies and the dental profession, and insured persons are given free choice amongst the dentists willing to provide treatment on the agreed scale.

Other widely adopted additional benefits are ophthalmic benefit (including the provision of spectacles), treatment in convalescent homes, and the provision of medical and surgical appliances.

Deposit Contributors.—Insured persons who do not join an approved society within a certain time after their entry into insurance fall automatically into a special class known as deposit contributors. Such persons are only entitled to benefits up to the limit of the amount standing to their own individual credit as the result of the contributions paid in respect of them, but the usual proportion of the cost of their benefits is paid by the State. The number of deposit contributors at the end of 1926 was 282,400. It is always open to a deposit contributor at any time to join any approved society which is prepared to admit him to membership. By the Act of 1928 a special insurance section was set up through which any deposit contributor who can prove that he is unable, by reason of the state of his health, to obtain admission to an approved society, is able to obtain the full normal benefits of the scheme on an insurance basis.

Central Administration.—The general supervision of the scheme of national health insurance on behalf of the central government is vested in the Minister of Health in England and Wales, and in the Scottish Board of Health in Scotland, and the cost of the central administration is borne by the Exchequer. It rests with the Minister to determine doubtful questions of insurability, to enforce the payment of the statutory contributions, and to satisfy himself that the scheme is properly administered by approved societies and insurance committees. The Minister is empowered to withdraw approval from a society which is found, after enquiry, to be administering the scheme in a manner prejudicial to the interests of its members.

Statistics.—The total number of insured persons at the end of 1926 was approximately 16 million, of whom more than 98 per cent were members of approved societies. The total income of the scheme for the year was about £37 million, of which £24½ million was derived from the contributions of insured persons and their employers; £7 million was paid by the Exchequer, and nearly £6 million was derived from interest on accumulated funds. The expenditure on benefits was about £32 million and the total cost of administration by approved societies, insurance committees and the central departments was approximately £5 million. The cost of administration was, therefore, about 13½ per cent of the total revenue of the scheme. The total accumulated funds at the end of 1926 amounted to £126 million.

Royal Commission on National Health Insurance.—A Royal Commission was appointed in 1924 to enquire into the scheme of national health insurance and to recommend any alterations or extensions which might be thought desirable. After hearing evidence from representatives of all bodies or persons participating in, or affected by, the scheme, the commission issued their report in 1926 and arrived at the conclusion that "national health insurance has established its position as a permanent feature of the social system in this country and should be continued on its present compulsory and contributory basis." The commission, however, made many recommendations for the improvement of the scheme in detail. Amongst the most important were that medical benefit should be extended to include a consultant and specialist service; that the insurance medical service should be properly co-ordinated with other health services, and that in order to promote this end the insurance committees should be abolished and their powers transferred to the county and county borough councils. A further important recommendation was that there should be a partial pooling of the surpluses of approved societies in order to provide the necessary funds for the proposed extension of medical benefit, and also to mitigate to some extent the inequalities between different approved societies arising out of favourable or unfavourable experience as revealed on valuation. A minority of the commission reported in favour of the abolition of the approved society system and the transfer of the administration of the cash benefits, as well as medical benefit, to the local health authorities.

Success of the Scheme.—There can be no doubt that the British scheme of national health insurance has thoroughly justified itself by its results. At the inception of the scheme considerable hostility and opposition were encountered. It did not meet with a favourable reception from the medical profession and was unpopular with large sections of employers and with some classes of insured workers. This opposition has now almost entirely disappeared. There can be no question that the benefits provided under the scheme are highly appreciated amongst the insured community and the contributions are paid with almost entire absence of friction. The financial success of the scheme has been demonstrated by the results of successive valuations, and the great majority of insured persons are receiving benefits substantially greater than the minimum provided under the act. The amount of distress amongst the working-classes occasioned by reason of sickness of the wage-earners has been materially reduced, with the result that expenditure on poor law relief is substantially less than it would have been in the absence of a scheme of national health insurance. As regards the effect of the scheme on the general health of the nation, it is difficult to produce any convincing statistics but the fact that all insured workers are entitled to free medical attendance immediately they have any need of it must obviously be conducive to prompt treatment of incipient illness, with a consequent lessening of more serious results. The general death rate has fallen materially since the scheme was introduced and it is reasonable to attribute this in some measure to the medical and other benefits provided under the scheme.

Northern Ireland.—The original National Insurance Act of 1911 applied to the whole of Ireland as well as to Great Britain, and as a consequence a scheme of national health insurance almost identical with that of Great Britain is still in operation in Northern Ireland. The most important variation is that medical benefit is not included in the Northern Irish scheme, but a benefit known as sanatorium benefit is provided. This benefit consists of the right of treatment in sanatoria or otherwise of insured persons suffering from tuberculosis. It is administered through the local insurance committees under arrangements made with the councils of the counties and county boroughs. The same benefit was originally provided in Great Britain but was discontinued in 1921 when the duty of making comprehensive arrangements for the treatment of tuberculosis amongst the whole population, insured and uninsured alike, was laid upon the county and county borough councils. Owing to the absence of medical benefit in Northern Ireland the rates of contributions are less than those in Great Britain by 2d. a week.

II. BRITISH DOMINIONS

In the Irish Free State similar provision is made to that in Northern Ireland, but up to 1928 no complete scheme of national health insurance had been brought into operation in any of the other self-governing dominions of the British Empire. In Australia a State scheme of non-contributory pensions for persons permanently incapacitated for work was introduced in 1908 in conjunction with the non-contributory old age pension scheme. Since 1912 there has also been a system of maternity allowances on a non-contributory basis. A Royal Commission was appointed in 1925 to investigate the subject of a complete scheme of national health insurance and it reported in 1927 in favour of the establishment of a general scheme on a compulsory and contributory basis. Up to 1928 no steps had been taken in Canada, South Africa or New Zealand towards the establishment of a State scheme of insurance against sickness but in each country public attention was being increasingly directed towards the desirability of such provision. (E. HA.)

III. UNITED STATES

In no other civilized country in the world has the principle of national health insurance, except as a subject of academic study, made less progress than in the United States. Owing to the newness of the country and its rich natural resources there has been opportunity for persons of ability in all groups. The incomes of the majority are higher than in other countries, and the development of private insurance and other private institutions to provide for emergencies is more extensive than in other countries. This has been augmented by the difficulties in enacting social legislation, due to the Federal form of government and the review of legislation by courts. Industrial workers are protected against incapacity due to accidents and in some States illness arising out of their employment, through compensation laws enacted by States and the Federal Government. The number of workers insured against sickness is about 25%; others are dependent upon savings. Though compulsory health insurance has been the subject of study and investigation at various times in certain States, no scheme has been actually brought into operation. A bill to set up a comprehensive scheme on a compulsory and contributory basis, following the German and British schemes in most respects, was introduced into the legislature of the State of New York in 1919 and was actually passed by the senate, but the strongest opposition was organized in various quarters and the measure did not succeed in becoming law. (X.)

IV. EUROPEAN COUNTRIES

Organized provision of some kind for the insurance of workers against sickness has been made in all European countries. Compulsory schemes are in operation in Austria, Bulgaria, Czechoslovakia, Germany, Hungary, Norway, Poland, Rumania, Russia and Yugoslavia, and in certain Cantons of Switzerland. In all these countries the schemes are on a contributory basis, the cost being shared between the employers and workers, except in Rumania, where the whole contribution is payable by the worker, and in Russia, where the whole cost falls on the employer. Some part of the cost of the scheme is borne by the State or other public funds in Bulgaria, Norway, Poland and Switzerland. Voluntary schemes, which receive assistance from public funds, and which cover a large proportion of all the wage-earners, are in operation in Belgium, Denmark, France, Sweden and Switzerland. In Holland a compulsory scheme of insurance against permanent invalidity was brought into force in 1919 but up to 1928 sickness insurance was still on a voluntary basis and received no assistance from the State. In Italy a scheme of compulsory maternity insurance for employed women was instituted in 1910, and compulsory insurance against invalidity in 1919, but although the question of the establishment of a general State scheme of compulsory sickness insurance had been under discussion, no provision other than through voluntary mutual benefit societies not aided by the State, had been made up to 1928.

There are three main differences between the schemes in force in European countries and the British scheme. In the first place,

while in Great Britain the contributions and benefits are on a flat rate, in other countries they are graded in accordance with the wages of the insured workers. Again, in Great Britain the weekly payments to the insured while incapacitated for work through illness are continued in the form of disablement benefit without any time limit after the maximum period of sickness benefit has been exhausted, but in the continental schemes the payments cease after a period, usually of 26 weeks but shorter in some countries and longer in others, and the insured person, if still remaining incapable of work, is not entitled to any further payment under the sickness insurance scheme. He may, however, then become entitled to relief under the scheme of invalidity pensions, which is separately administered, either as an independent scheme or in conjunction with the State scheme of old age pensions. Finally, in contrast to the British system of approved societies as agencies for the administration of the cash benefits, the insurance institutions in continental countries are in general organized on either a territorial or an occupational basis, or both.

International Conference on Sickness Insurance.—An International Labour Conference on Sickness Insurance was held at Geneva in 1927 under the auspices of the League of Nations. Delegates from 43 countries were present and the arrangements for sickness insurance in each of these countries were passed under review. As a result the conference adopted a convention with regard to sickness insurance which was remitted for ratification to all the States members of the League. The scheme outlined in this convention was similar in all essentials to that in force in Great Britain. All countries which ratify the convention pledge themselves to set up a compulsory scheme of sickness insurance applicable both to manual and non-manual workers, deriving its income from contributions by workers and their employers, and providing medical attendance for the insured workers, together with cash payments in compensation for loss of wages through sickness. There is therefore reason to hope that provision substantially equivalent to that under the British scheme described above will before long exist in most European countries.

BIBLIOGRAPHY.—The whole of the statutory provisions with regard to national health insurance in Great Britain is to be found in the *Statutes, Regulations and Orders relating to National Health Insurance*, published by H.M. Stationery Office. The best critical review of the scheme is contained in the *Report of the Royal Commission on National Health Insurance*, Cmd. 2596 of 1926. Much interesting information with regard to the financial and actuarial aspects of the scheme is to be found in the *Report by the Government Actuary on the Second Valuation of Approved Societies*, Cmd. 2785 of 1927, and in *National Health Insurance, a Statistical Review*, Watson, J.R.S.S., Vol. 90, Part 3. For comparative statements of the schemes in different European countries, reference should be made to various publications of the International Labour Office, Geneva, and in particular to *General Problems of Social Insurance*, Studies and Reports, Series M. No. 1, 1925 and *Compulsory Sickness Insurance*, Studies and Reports, Series M. No. 6, 1927. Miller, *Social Insurance in the United States* (1918) and Morgan, *Public Relief of Sickness* (1923). (E. HA.)

NATIONAL INSURANCE: WIDOWS' AND ORPHANS' PENSIONS. The first quarter of the 20th century was remarkable for the rapid development of schemes of social insurance. The article that follows deals with developments in Europe. These do not exist in the United States except in the form of Mothers' pensions, an account of which will be found in the article PENSIONS: *The United States*. While at first the schemes were directed to the protection of the workman himself, the necessity of making provision for the family when death removes the breadwinner has increasingly claimed attention. In Great Britain the problem of the widow and fatherless children received special consideration in the Report of the Royal Commission on the Poor Laws, published in 1909. The subject was debated in the House of Commons for the first time in 1919, and afterwards in 1923, 1924 and 1925. There was general agreement as to the desirability of establishing a scheme of pensions for widows, but the debates showed divergence of opinion as to the method of financing the scheme. Within a month after the last debate Mr. Winston Churchill in introducing the Budget announced that the Government had decided to bring in a Bill establishing widows' and orphans' pensions and old age pensions at the age of 65. The Widows', Orphans' and Old Age

Contributory Pensions Bill, the second reading of which was moved by the Minister of Health, Mr. Neville Chamberlain, on May 18, 1925, proclaimed that the Government had adopted the contributory principle. It became law, and the provisions relating to widows and orphans came into operation on Jan. 4, 1926.

Scope of the Scheme.—The scheme is contributory and compulsory and is interlocked with the national health insurance scheme (*see* NATIONAL INSURANCE: HEALTH), all persons insured under the latter, whether as employed or as voluntary contributors, being within the scope of the widows' and orphans' scheme. Employed contributors are persons compulsorily insured and consist in the main of persons employed under a contract of service, with a remuneration limit of £250 per annum in the case of persons employed in a non-manual capacity. Two comparatively small classes who are not insured under the health insurance scheme are compulsorily insured for widows' and orphans' pensions. These classes consist of men who hold certificates exempting them from liability to be insured under the National Health Insurance Act and of persons employed in certain types of "excepted employment." Voluntary insurance under the National Health Insurance Act is limited to persons who, having previously been compulsorily insured for a minimum period, elect within a specified time to continue as voluntary contributors. On the same principle the right to continue as voluntary contributors is given on certain conditions to persons who were previously insured compulsorily for widows' and orphans' pensions only, *i.e.*, as exempt men or as persons in excepted employment.

The Pensions Act made a further addition to the classes of persons eligible for voluntary insurance. As a married woman is debarred from being a voluntary contributor under the Health Insurance Act, the Pensions Act provides that an uninsured man may become a voluntary contributor within a prescribed time after his marriage to an insured woman if certain conditions attaching to her previous insurance are satisfied, so that her insurance before marriage gives *inter alia* the opportunity of acquiring a title to a widow's pension.

Contributions.—The normal contribution, 9d. a week for a man and 4½d. for a woman, includes the contribution for old age pensions between 65 and 70. Exempt men, however, and the majority of persons in excepted employment are not insured for old age pensions and their contributions, for widows' and orphans' pensions only, are 7d. for men and 3½d. for women. It is to be observed that the woman's contribution, which in general is half the man's contribution, is not based solely on the value of the benefits which flow from her own insurance.

From the starting point that the contribution of the insured woman would be equal to half the contribution of the insured man, it was found that the appropriate contribution to provide all the benefits of the Act (including old age pensions between the ages of 65 and 70) in the case of a boy of 16, the age at which contributions begin, was 10d. a week. Certain savings, however, resulting to the Exchequer from adjustments in Unemployment Insurance consequent on the Pensions Act were taken into consideration and as a result the rate of contribution was fixed at 9d. per week, a uniform rate for all men without having regard to their age at the date that they became insured. As the contributions are based on the rates appropriate to those entering the scheme at the age of 16, they are insufficient to provide the benefits for entrants over that age. The residual liability is carried by the Exchequer. In the first two years the contributions were more than sufficient to meet the payments but thereafter there is a growing demand on the Exchequer. This liability, which includes the Exchequer's contribution to old age pensions between 65 and 70, was estimated to amount to a net total of £46,000,000 over the first ten years, and the Act provides for its liquidation by a uniform payment of £4,000,000 a year.

The contribution for men is divided between the employer and employee in equal shares except in the case of the exempt man, where the employer pays his normal contribution of 4½d. and the employee 2½d. In the case of women 2½d. (excepted women 2d) is paid by the employer and 2d (excepted women 1½d) by the employee. Although an exempt woman is not insured under the

pensions scheme her employer is required to pay his normal contribution of 2½d a week.

Contributions begin at the age of 16 and, as regards the employee's portion, cease at 65 but the employer's liability to contribute terminates only on the termination of employment. The employer's contribution for an employee over 65 is 9d (for a woman 7d) but as his contribution for health insurance (4½d for man or woman) ceases on the employee attaining 65, his total liability under the two schemes is unaltered. The employer pays the weekly contributions for health and pensions by affixing a single stamp to the contribution card of the employee and he is entitled to recover the employee's share by deduction from wages. For persons in excepted employment, who are outside the health insurance scheme, contributions are paid periodically in cash. The contributions for voluntary contributors are the same as for employed contributors, *viz.* 9d and 4½d for men and women respectively, the whole amount being paid by the contributor.

The number of insured persons paying contributions during the first year of the scheme was approximately 16,300,000.

Benefits and Qualifications.—The benefits for widows and orphans—an orphan is defined as a child both of whose parents are dead—are:—

(1) Widow's pension—a payment of 10/- a week to the widow of an insured man until she reaches the age of 70 or marries, with an additional allowance for children under the age of 14 or under the age of 16 if still at school, at the rate of 5/- a week for the eldest and 3/- a week for each other child.

A widow who is in receipt of a widow's pension on reaching the age of 70 is entitled to an old age pension at the same rate. A widow on remarriage continues to receive the allowance for children under the specified age. The allowance for children is, on the death of the widow, transformed into orphans' pensions.

(2) Orphans' pensions—a payment of 7s. 6d. a week for each child, under the specified age, of an insured man, being a married man or a widower, or of an insured widow.

An orphan's pension is payable to the guardian or other person having the charge of the child.

The qualifying conditions are: (i.) the insured person must have been insured for not less than 104 weeks and not less than 104 contributions must have been paid: (ii.) over the three contribution years (running from July in one year to June in the next) preceding his death an average of 26 contributions a year must have been paid, but for this purpose weeks of incapacity for work due to sickness and weeks of genuine unemployment count as weeks for which contributions were paid: (iii.) he must have been resident in Great Britain for two years immediately prior to his death and his last employment (excluding temporary employment) must have been in Great Britain. The last condition does not apply to soldiers, sailors and airmen.

A pension or an additional allowance is not payable to or for any person (a) while an inmate of a poor law institution, unless admission was for the purpose of obtaining medical or surgical treatment, when there is no disqualification, up to a maximum of three months from date of admission, so long as treatment continues: (b) while detained in a lunatic asylum: (c) while being maintained in any place as a pauper-lunatic or criminal lunatic: (d) while undergoing a period of imprisonment given without the option of a fine. A widow is not entitled to her pension, but the additional allowance remains payable to her, while she is cohabiting with a man as his wife.

With certain exceptions, a person who is receiving a World War pension for the death of any person, other than a son, is not entitled to a pension under the Act, but if the pension which otherwise would have been payable under the Act is the greater, the excess is paid as an addition to the War Pension. A similar provision applies to a person who is receiving a pension for the death of any person whose death was attributable to service at any time with the naval, military or air force.

When compensation is received for a child under the Workmen's Compensation Act, the additional allowance or orphan's pension under the Act is payable only to the extent that it exceeds the weekly value of the compensation. The widow's pension of

10/- a week is unaffected by the receipt of compensation.

Non-contributory Classes.—Exceptional provision was made for the widows and children of men who, having died before Jan. 4, 1926, the date of the commencement of the Act, could not have participated in the contributory scheme. The rates of widows and orphans pensions are the same as under the contributory scheme, but a widow in this class is only entitled to a pension if there was a child under the age of 14 at the commencement of the Act, and she ceases to be entitled six months after her youngest child reaches the age of 14.

The capital value at the commencement of the Act of the total amount which the Exchequer would have to provide for these non-contributory classes was estimated at £42,000,000.

In the restricted provision made for the widow this non-contributory section of the scheme is closely in line with most of the non-contributory schemes of mothers' pensions which operate in several parts of the British Dominions and in many States of the U.S.A. The widow as widow was not the object of the benefit. The provision was designed entirely in the interests of the children.

Administration.—In England and Wales the scheme is administered by the Minister of Health and in Scotland by the Scottish Board of Health. Claims for pension are made on forms which are obtainable at all Post Offices. Successful applicants receive a notice from the Department for presentation at the Post Office which they nominated on their claim forms and are given in exchange a book containing a series of weekly orders. Bound up in every order book is a form which the pensioner completes shortly before the currency of the book expires, thereby requisitioning a new book.

Number of Pensions.—Up to March 31, 1928, 123,136 widows' pensions and 4,306 orphans' pensions had been awarded under the contributory part of the scheme, and 132,554 widows' pensions and 15,705 orphans' pensions under the non-contributory part. On the same date the numbers actually in receipt of pensions or allowances under the scheme were: contributory, 112,525 widows and 88,547 children: non-contributory, 94,172 widows and 180,294 children.

British Dominions and Northern Ireland.—None of the Dominions has a contributory scheme of widows' and orphans' pensions, but non-contributory schemes, which provide assistance to needy and worthy mothers for the care of their children in their own homes, have been established in Canada (Alberta, British Columbia, Manitoba, Ontario and Saskatchewan), Australia (New South Wales) and New Zealand.

The Widows', Orphans' and Old Age Contributory Pensions Act (Northern Ireland) was passed on Nov. 6, 1925. In all essential particulars its provisions are identical with those of the British Act. Reciprocal arrangements between Great Britain and Northern Ireland were at once made, with the result that contributions paid in Great Britain rank as valid contributions in connection with a claim for pension made in Northern Ireland and vice versa.

European Countries.—In several countries provision for the widow and children of a deceased insured person is made under contributory schemes providing invalidity and old age pensions. Pensions for the widow and children are usually based on the invalidity or old age pension to which the deceased was entitled, and the proportion varies considerably in different countries, from 20 to 50% for the widow and from 10 to 50% for the children. Pensions to widows and children are paid in Germany (salaried employees' scheme), Austria (salaried employees' scheme), Belgium and the Netherlands. Children's pensions are payable under the manual workers' scheme in Germany and under schemes in Czechoslovakia and Yugoslavia, but in these cases the provision made for the widow is limited: in Germany her pension is deferred until she is 65 unless she is unable to work, in Czechoslovakia she is entitled only if unable to work, and in Yugoslavia her pension ceases three years after her husband's death.

A non-contributory scheme exists in Denmark under which indigent widows have the right to a public contribution towards the support and education of children under 14.

BIBLIOGRAPHY.—*Report by the Government Actuary on the Financial Provisions of the Widows', Orphans' and Old Age Contributory*

Pensions Bill (Cmd. 2406, H.M. Stationery Office), contains a detailed explanation of the financial basis, estimates of the future number of beneficiaries and future cost of the scheme in selected years up to 1965-66. *General Problems of Social Insurance* (Internat. Labour Office, League of Nations), contains a review of the position of social insurance in general. *Social Insurance* (the Report of League of Nations Union Conference, Nov. 1925), contains *inter alia* a report of a discussion on the scheme of the 1925 Act, in which the relative merits of contributory and non-contributory schemes are argued.

NATIONALITY AND NATURALIZATION. Nationality may be defined as the quality of being a national of a given State. It may be pointed out by way of abundant caution that in the British empire the term nationality is used only in the political sense, since the empire having no common law, the personal law of a British subject is determined not by his nationality, but by his domicile. In those States where the national law prevails throughout their respective territories, the necessity for this distinction does not arise. Political and civil status are synonymous. The law of British nationality then now rests upon the common law and upon three statutes, viz., the British Nationality and Status of Aliens Act 1914 which came into operation on Jan. 1, 1915, which professed to be a consolidating and amending statute, and which repealed a number of former enactments; the Amending Act 1918; and the Amending Act 1922. These statutes are now officially printed as one statute and cited as the British Nationality and Status of Aliens Acts 1914-22.

At common law, with certain exceptions to be mentioned later, all persons born within the British dominions are natural-born British subjects. For instance the child of French parents born during their temporary residence in England is a British subject and liable to be convicted of high treason if he took part in hostile operations against Great Britain (see *Aeneas Macdonald's Case* 18 State Trials, 857).

By s. 1 (1) of the statute the following persons are deemed to be natural-born British subjects, viz.:—(a) "Any person born within His Majesty's dominions and allegiance." It was necessary to add the condition of birth *within the allegiance* of the king in order to prevent the acquisition of British nationality by a child born to an enemy father within the British dominions at the time in the occupation of the enemy or by a child born to a foreign sovereign or foreign ambassador or diplomatic agent. (b) "Any person born out of His Majesty's dominions whose father was at the time of that person's birth a British subject, and who fulfils any of the following conditions, that is to say, if either (i.) his father was born within His Majesty's allegiance; or (ii.) his father was a person to whom a certificate of naturalization had been granted; or (iii.) his father had become a British subject by reason of any annexation of territory; or (iv.) his father was at the time of that person's birth in the service of the Crown; or (v.) his birth was registered at a British consulate within one year or in special circumstances, with the consent of the secretary of State, two years after its occurrence, or in the case of a person born on or after the first day of Jan. 1915, who would have been a British subject, if born before that date, within 12 months after the first day of Aug. 1922." (c) "Any person born on board a British ship whether in foreign territorial waters or not: provided that the child of a British subject, whether that child was born before or after the passing of the act, shall be deemed to have been born within His Majesty's allegiance if born in a place where by treaty, capitulation, grant, usage, sufferance or other lawful means, His Majesty exercises jurisdiction over British subjects. Provided also that any person whose British nationality is conditional upon registration at a British consulate shall cease to be a British subject unless within one year after he attains the age of 21 or within such extended period as may be authorized in special cases by regulations made under this act (i.) he asserts British nationality by a declaration of retention of British nationality in such manner as may be prescribed by regulations made under the act; and (ii.) if he is a subject or citizen of a foreign country under the law of which he can, at the time of asserting his British nationality, divest himself

of the nationality of that foreign country by making a declaration of alienage or otherwise, he divests himself of such nationality accordingly."

By the act of 1772 a child born out of the British dominions whose father or whose grandfather was born within those dominions was deemed to be a natural-born British subject, provided that his father at the time of his death had not ceased to be a British subject. By the act of 1914, however, this privilege was taken away from grandchildren born after Jan. 1, 1915, outside the British dominions. Such children were not British subjects unless their father had been born within the British dominions, with the exception of those children born in a place where by treaty, capitulation, etc., His Majesty exercised jurisdiction over British subjects. But owing to the agitation by British subjects resident in foreign countries and particularly by those residing in the Argentine—the British colony in Buenos Aires numbered some 30,000—the act of 1922 was carried, which provides that a British subject who has a child born abroad after Jan. 1, 1915, may secure British nationality for such child by registering its birth at a British consulate in the manner above stated. Consequently British subjects, whether natural-born or not, living abroad can extend British nationality to their descendants in perpetuity.

In *Carlebach's Case*, 1915, 3 K.B. 716, it was held that under the act of 1870 a naturalized British subject could not transmit his nationality to his children born abroad, who consequently became aliens. Now by the act of 1914 such children born abroad after Jan. 1, 1915, are deemed to be natural-born subjects. And by iii. and iv. of para. (b) of subsect. (1) the provisions of the common law are enlarged and the children of a father wherever born who, at the time of their birth, had become a British subject by reason of any annexation of territory, or who was in the service of the Crown, are deemed to be natural-born British subjects.

(d) "Any person born on board a British ship whether on the high seas or in foreign territorial waters is a British subject." The term "British ship" includes vessels of the royal navy and of the navies of the dominions, and vessels as defined by s. 1 of the Merchant Shipping Act 1894, viz., vessels owned wholly by natural-born British subjects, by naturalized British subjects, by British denizens, and by corporations established under and subject to the laws of some parts of His Majesty's dominions and having their principal place of business in those dominions.

It should be noted that the act is not retrospective, except as otherwise expressly provided. Consequently the old law applies to those born prior to Jan. 1, 1915.

Naturalization is the act of investing an alien with the status of a national in a given State. Aliens may still acquire British nationality by a private act of parliament or may become denizens by grant of letters of denization by the Crown. The former process is extremely rare. When the late Lord Reay succeeded to a Scottish peerage in 1877 he was naturalized by act of parliament. The latter although preserved by s. 25 of the act of 1914 is likely to fall into disuse owing to the disqualifications which still attach to denizens. By s. 2 of the act an alien may obtain a certificate of naturalization from the secretary of State provided he has resided in His Majesty's dominions for not less than five years or been in the service of the Crown for not less than five years within the last eight years, is of good character and has an adequate knowledge of the English language and intends to reside in His Majesty's dominions or to continue in the service of the Crown. He must have resided in Great Britain for at least one year immediately preceding his application. The grant of such certificate lies in the absolute discretion of the secretary of State and the certificate does not take effect until the applicant has taken the oath of allegiance. A person to whom a certificate is granted is entitled to all political and other rights, powers and privileges and is subject to all obligations, duties and liabilities as a natural-born British subject and to all intents and purposes enjoys the status of a natural-born British subject (s. 3 [1]). By the Act of Settlement 1700, naturalized persons and denizens could not be privy councillors, or members of either House of Parliament, or enjoy any office or place of trust, civil or military,

or take any grant of lands from the Crown. *Quoad* naturalized aliens these disqualifications were abolished (s. 3 [2]; see *Rex v. Speyer*, 1916, 2 K.B. 858). The secretary of State may also grant a special certificate of naturalization to any person with respect to whose nationality a doubt exists (s. 4); and may include in a certificate the name of any infant born before the date of such certificate and such child may within one year of obtaining his majority make a declaration of alienage and thereupon cease to be a British subject (s. 5). A certificate of naturalization may be revoked by the secretary of State if it has been obtained by false representation or fraud or by concealment of material circumstances, or if the person to whom the certificate is granted has shown himself to be disaffected or disloyal, or by reason of other specified grounds (s. 7). The wife and children may be included in this revocation, but if not they remain British subjects. The wife may, however, make a declaration of alienage for herself and her infants (s. 7, A).

British nationality is lost by foreign naturalization. Until the Naturalization Act 1870, the maxim *nemo potest exuere patriam* prevailed. By s. 6 of that statute a British subject by voluntary naturalization in a foreign State ceased to be a British subject. But it was subsequently held in *R. v. Lynch*, 1908, 1 K.B. 444 that this section did not enable a British subject to become naturalized in an enemy State during time of war. The section was substantially re-enacted by s. 13 of act of 1914. But it would appear from the decision in *Pedlar v. Johnson*, 1920, 2 I.R. 450 that a British subject may become naturalized in a neutral State during time of war and engage in acts of hostility against his State of origin without sacrificing his rights as a friendly alien.

(H. H. L. B.)

United States.—Nationality rests upon the fundamental law of the United States, its Constitution, or enactments of Congress and treaties made pursuant thereto, whether the individual be of native or of foreign birth. In art. I., s. 8, clause 4 of the Constitution, among the powers given to Congress is that to "establish a uniform rule of naturalization." The First Congress exercised this power in the enactment of the statute of March 26, 1790 (1 Stat. 103), by which a rule was established for the acquisition of citizenship in the United States by those of foreign birth. This Act was based upon the principle of the right of expatriation as inherent in the individual, which principle was declared in affirmative form in the Act of July 27, 1868 (15 Stat. 223), referred to hereinafter.

The statute of 1790 also asserted the doctrine of *jus sanguinis* (status by blood) in declaring as citizens the children of citizens of the United States though born beyond the sea or out of the limits of the United States. By this Act the Congress refused to recognize citizenship as descending through such foreign-born citizens as did not reside in the United States prior to the birth of children. See also Acts of April 14, 1802 (2 Stat. 155) and Feb. 10, 1855 (10 Stat. 604), the latter now appearing as s. 1993 of the Revised Statutes of the United States. These Acts of Congress declaring certain classes of persons to be citizens have been recognized by the Supreme Court of the United States as the exercise of a constitutional authority (*U.S. v. Wong Kim Ark*, 1898, 169 U.S. 649, 703, and *Weedin v. Chin Bow*, 1927, 274 U.S. 657).

The following words of s. 1 of Amendment XIV. of the Constitution of the United States, proclaimed July 28, 1868, give recognition to the doctrine of *jus soli* (status by country of birth): "All persons born or naturalized in the United States, and subject to the jurisdiction thereof, are citizens of the United States and of the State wherein they reside." Birth, therefore, confers citizenship notwithstanding there may be racial ineligibility of the parents for naturalization (*U.S. v. Wong Kim Ark*, 169 U.S. 649).

Congress has both conferred citizenship and fixed the national status of the inhabitants of certain territory through its treaty-making powers, and by statute pursuant thereto from time to time effected their collective naturalization either prior to or upon the admission of such acquired territory to statehood. Such action was taken in territory acquired under treaties concluded with Great Britain—Territory of Michigan (1794, 8 Stat. 116); France—Louisiana (1803, 8 Stat. 200); Spain—Florida (1819, 8 Stat.

252); Mexico—Guadalupe-Hidalgo (1848, 9 Stat. 922) and Gadsden (1853, 10 Stat. 1031); Russia—Alaska (1867, 15 Stat. 542); Denmark—Virgin Islands (1916, 39 Stat. 1706).

In the absence of definite treaty stipulations, citizenship has been conferred upon inhabitants of acquired territory by legislative enactments prior to statehood. In this category may be included the Hawaiians (Act of April 30, 1900, 31 Stat. 141) and Porto Ricans (Act of March 2, 1917, 39 Stat. 953). United States citizenship was conferred collectively through the political incorporation of the original States into the United States also in the case of the State of Texas upon its annexation and direct admission into the Union as a State.

Congress formerly dealt with the Indian natives of the United States by treaty but afterwards by statute subsequent to the law of March 3, 1871 (16 Stat. 566). Certain of these acquired citizenship from time to time but all North American Indians born within the territorial limits of the United States were given citizenship by the Act of June 2, 1924 (43 Stat. 253).

The natives of the Philippine islands acquired the status of United States nationals under the treaty of peace with Spain, concluded Dec. 10, 1898 (30 Stat. 1759). The Philippine legislature, by enactment of March 26, 1920, provided for the naturalization of persons as Philippine citizens.

Citizenship is open to aliens who are free white persons and to aliens of African nativity or descent (s. 2169 R.S.U.S.). Aliens of the Japanese and Hindu races have been decided to be inadmissible by the Supreme Court (*Takao Osawa v. U.S.*, 1922, 260 U.S. 178, and *U.S. v. Bhagat Singh Thind*, 1923, 260 U.S. 204). Chinese are excluded by the Act of May 6, 1882 (22 Stat. 61).

Naturalization Procedure.—On June 29, 1906, Congress repealed with but slight exception the then existing naturalization laws and enacted one major law or rule (34 Stat. 596). This law and the unrepealed laws are under the special supervision of a Federal commissioner of naturalization at Washington in the Bureau of Naturalization of the Department of Labor. This bureau has branch offices throughout the United States, strategically located in 27 cities.

On Sept. 22, 1922, by Act of Congress (42 Stat. 1021), women were required to become citizens independently of their husbands, with the repeal of s. 1994 of the Revised Statutes of the United States, by which a foreign-born woman acquired citizenship on marriage to an American citizen. By this Act of 1922 an American woman citizen who marries an alien racially ineligible to citizenship loses and cannot regain her citizenship during the continuance of the marital status.

Naturalization is a judicial proceeding, determinable by the district courts of the United States, and by the State courts of original jurisdiction in law or equity or law and equity in which the amount in controversy is unlimited. These State courts have been clothed by Congress with concurrent Federal authority for this purpose. In such a proceeding an alien, who has been admitted to the United States in conformity with the immigration laws for permanent residence, may declare his intention as soon as he desires before the clerk of the court within the jurisdiction of which he resides. Upon completion of five years of continuous residence within the United States he may petition the court of the jurisdiction where he then resides for admission to citizenship, if at that time his declaration of intention is two years old, or at such time as it shall become two years old. Two citizens of the United States as witnesses must be present so as appropriately to prove his allegations of residence and establish his good moral character and attachment to the principles of the Constitution. A woman who is the wife of an American citizen, or who lost her citizenship through marriage to an alien eligible for citizenship, is not required to make the preliminary declaration of intention and is required to have only one year of residence in the United States immediately preceding the time she petitions for naturalization. A period of 90 days must intervene after filing a petition before the court may hear it. Exceptions are allowed to certain aliens such as sailors and soldiers. The officers of the Naturalization Bureau examine the applicant and witnesses and appear in court on behalf of the Government at the hearing. Before many Federal

courts they have a quasi-judicial authority in determining admissibility. A certificate of citizenship, furnished by the Bureau of Naturalization, is issued to the newly naturalized citizen by the clerk of the court. The costs are \$1.00 for a declaration of intention, and \$4.00 for the petition to the court and certificate of citizenship, if granted.

An alien born child derives citizenship through the acquisition of that status by the parent if the child take up permanent residence in the United States prior to its attainment of the age of 21 years (s. 2172 R.S.U.S.; s. 5, Act of March 2, 1907, 34 Stat. 1229; *Kaplan v. Tod*, 267 U.S. 229).

Protection Abroad.—All children born and residing outside of the United States who acquire citizenship through their fathers, are, in order to receive the protection of the United States Government, required upon reaching the age of 18 years to record their intention to become residents of the United States and to remain citizens thereof. They are further required to take the oath of allegiance to the United States on attaining the age of 21 years.

Citizenship acquired by naturalization is a conditional status. It shall be presumed to cease upon residence for two years in the State of former allegiance or for five years in any other foreign State. This presumption may be overcome upon the presentation of satisfactory evidence to a diplomatic or consular officer of the United States under rules of the Department of State. An oath of allegiance to or naturalization in any foreign State accomplishes expatriation of an American citizen, whether native or naturalized.

Recent Legislation.—Certificates of citizenship are obtainable by those who are citizens through the naturalization of the parent, and by women who acquired citizenship through the citizenship of their husbands during the time citizenship was acquired by marriage, if the citizen is in the United States.

Costs for a certificate showing the date, place and manner of lawful arrival of the alien in the United States are \$5.00; for the declaration of intention, \$5.00; for the petition to the court and the certificate of citizenship if granted, \$10.00; for a certificate of citizenship issued by the commissioner of naturalization to a foreign-born person who has acquired citizenship through the parent or the husband, and for a special certificate of citizenship to be issued for the purpose of securing recognition as an American citizen by the former sovereignty, to be delivered through the Secretary of State to such sovereignty, \$10.00; for a new declaration of intention or a new certificate of naturalization in lieu of one lost or destroyed, \$10.00. (R. F. C.)

France.—French nationality attaches to (1) children born anywhere of a French father; (2) children born in France (a) of unknown parents or of parents of unknown nationality; (b) of foreign parents, one of whom was born in France; (c) of foreign parents not born in France (see *Code Civil* Liv. i. tit. i.). By the law of Aug. 10, 1927, every male born in France of a foreign father, and domiciled, becomes French on making the required declaration under the age of 18. At 21 he would become French, but has a year to disclaim. An alien of 18 may become naturalized after uninterrupted residence of three years. An alien woman marrying a Frenchman is thereby naturalized only if by her national law she loses her former nationality, or on her express demand. The whole subject is now governed by the law mentioned.

Germany.—By Art. 110 of the Constitution of 1919, nationality in the Federation and in the States is acquired and lost in accordance with the provisions of a federal law. Every subject of a State is a subject of the Federation. By s. 2 of the Law of Nationality and Naturalization 1870, citizenship of a State is acquired by (1) descent, (2) legitimation, (3) marriage, (4) admission, and (5) naturalization. Admission is confined to Germans and naturalization to aliens. Both are conferred by a certificate. S. 2 was re-enacted in the Law of Nationality of the empire of July 22, 1913, by which imperial nationality must be conferred upon similar terms. By s. 25 a German by obtaining the written consent of the competent authorities of his home State could retain his German nationality even though naturalized in a foreign country. Germany, however, was constrained by Art. 278 of the Versailles Treaty of June 28, 1919 to undertake to recognize any

new nationality which had or might be acquired by her nationals under the laws of the Allied and Associated Powers.

Other Countries.—For the nationality and naturalization laws of the following countries, viz., Afghanistan, Austria, Belgium, China, Danzig, Denmark, Ecuador, Egypt, Esthonia, Greece, Honduras, Italy, Japan, Latvia, Lebanon and Syria, Lithuania, Monaco, Norway, Peru, Poland, Rumania, Russia (Soviet Union), Spain, Sweden, Switzerland, Syria, Tunis, Turkey, United States and Venezuela, reference should be made to *Parliamentary Papers*, Misc. No. 7 (1922), Misc. No. 2 (1927), and Misc. No. 8 (1927). NATIONALIZATION: see COLLECTIVISM, SOCIALISM.

NATIONAL OLD TRAILS ROAD, an American highway, the only one originally built by the U.S. Government. It was conceived by George Washington in Colonial days, financed by Congress on admitting Ohio into the Union in 1802, and extended by Congress in 1825 to Santa Fe, then in Mexico. In 1837 it passed under State control. It is variously known as the "National Pike," "Cumberland road" and "Santa Fe trail." It extends from Washington, D.C., to Los Angeles, Calif., a distance of 3,006 m., and it is the most northerly all year road from the Atlantic to the Pacific. It has more miles of pavement than any other highway in America, permits the fastest road transit from coast to coast, and carries more transcontinental travel than any other two highways. It traverses many scenic wonders, including the Grand Canyon of the Colorado and Petrified Forest and offers an unsurpassed view of Pikes Peak and the Spanish Peaks of the Rocky mountains. It is largely due to the initiative of Judge G. M. Lowe. It passes through Columbus, O., Indianapolis, Ind., St. Louis and Kansas City, Mo., Great Bend, Kan., La Junta, Col., Santa Fe and Socorro, N.M., St. Johns, Ariz., and San Bernardino, Calif.

NATIONAL PARKS AND MONUMENTS, THE, of the United States are reservations set aside by Congress for the benefit and enjoyment of the people. In 1929 there were 21 of these reservations administered by the national park service of the department of the interior, and 59 related reservations known

as national monuments, of which 32 are administered by the national park service.

One of the main distinctions between these two classes of reservations is the method of establishment. National parks are areas of unusual scenic beauty or natural phenomena, set aside by Congress "to conserve the scenery and the natural and historic objects and the wild life therein, and to provide for the enjoyment of the same in such manner and by such means as will leave them unimpaired for the enjoyment of future generations," to quote from the organic act of Aug. 25, 1916, establishing the national park service. The national monuments, on the other hand, are reservations established by presidential proclamation under authority granted the president of the United States in the act of June 8, 1906, known as the Antiquities Act, "to declare by public proclamation historic landmarks, historic and prehistoric structures and other objects of historic or scientific interest that are situated upon lands owned or controlled by the Government of the United States to be national monuments." Generally speaking the national monuments are small areas reserved to protect objects of historic, prehistoric or scientific value within their boundaries, while the national parks are larger areas containing scenery of the first order. Several of the existing national parks, however, were originally designated national monuments, to prevent their settlement or spoliation while awaiting the necessary legislation to give them park status. Among these were the Grand Canyon, Zion, Lassen Volcanic and Lafayette.

National Park Service.—For many years the various national parks and national monuments under the jurisdiction of the department of the interior were handled as an incidental item to the work of the miscellaneous division of the office of the secretary. In 1915 the secretary of the interior, the Hon. Franklin K. Lane, realizing the desirability of correlating and developing national park work, appointed an assistant in charge of national parks, pending the establishment of a separate bureau to handle this work. On Aug. 25, 1916, the president signed legislation entitled "An act to establish a national park service, and for other purposes." In the following April the bureau was established with headquarters in Washington, D.C.

The general administrative work of the national park service is carried on in the Washington office. Here are prepared detailed estimates of appropriations needed for park work and accurate cost records kept of Government money expended. Every matter of policy for the management of the parks is referred to the Washington office for final decision; every employé in the field is appointed through headquarters; and the general public relations work of the service, including the preparation and distribution of park literature, publicity and maps, is handled there.

Local Administration.—Each of the national parks is in charge of a local superintendent. In several of the smaller parks the superintendent has only two or three assistants, while in the more extensive, such as Yellowstone and Yosemite, a large force is necessary, both clerical and protective. The protective work is done by the ranger force, headed by a chief ranger who reports to the superintendent. The permanent ranger force is the all-year nucleus around which is built up the larger summer force.

The more important of the national monuments are in charge of local custodians. The group of south-western national monuments is in charge of a superintendent, through whom the custodians report. In addition to the field forces at the national parks and monuments, there are three field divisions at large promoting specialized lines of development. These are the educational, the civil engineering, and the landscape architectural divisions with headquarters in San Francisco, California.

Policy Governing National Park Creation and Administration.—The national park system is unequalled for scenic grandeur, and it is an established policy that additional areas chosen for park status must be worthy of the dignity and prestige of the existing parks. Park projects, to receive favourable recommendation from the department of the interior, must contain scenery of distinctive quality or some natural features so extraordinary or unique as to be of national interest and importance, such as typical forms of world architecture.

National parks and monuments in order of establishment	Location	Area	Special features
Hot Springs 1832	Arkansas	1½ sq.m.	Reserves for the use of all citizens of the nation its hot springs, believed to possess healing properties.
Yellowstone 1872	Wyoming, Montana and Idaho	3,348 sq.m.	Believed to contain more and greater geysers than all the rest of the world. Grand Canyon remarkable for its gorgeous colouring and waterfalls. As a wild bird and animal preserve unequalled in the United States, containing herd of approximately 1,000 head of buffalo, antelope herd and large numbers of deer, elk, bear, mountain sheep and many smaller animals.
Yosemite 1890	California	1,126 sq.m.	Yosemite valley world-famed for its beauty. Contains interesting section of the Sierra Nevada mountains, many waterfalls of extraordinary height and three groves of the rare <i>Sequoia gigantea</i> trees.
Sequoia 1890	California	604 sq.m.	Magnificent groves of big trees, or <i>Sequoia gigantea</i> . The largest, the General Sherman, is 37.3 ft. in diameter and 273.9 ft. high. Scores of sequoias 20 to 30 ft. in diameter and thousands over 10 feet. Includes Mt. Whitney, highest mountain in continental United States outside of Alaska, and other interesting high Sierra country.
General Grant 1890	California	4 sq.m.	Preserves the General Grant tree, 40.3 ft. in diameter and 266.6 ft. high.
Mount Rainier 1899	Washington	325 sq.m.	Contains largest accessible single-peak glacier system in the United States. From the summit and cirques of Mt. Rainier 28 named glaciers move slowly downward. There are 48 sq.m. of glaciers, ranging in width from 500 ft. to 1 m. and in thickness from 50 ft. to many hundreds, perhaps more than 1,000 feet. Famous for its subalpine wild flower fields.
Crater Lake 1902	Oregon	240 sq.m.	Large lake of extraordinary blueness located in the crater of an extinct volcano, 6 m. in diameter, with a maximum depth of 2,000 feet. It lies 1,000 ft. below the crater rim.
Platt 1902	Oklahoma	1½ sq.m.	Contains sulphur and other springs believed to possess medicinal qualities.
Wind Cave 1903	South Dakota	17 sq.m.	Cave contains several miles of galleries and numerous rooms.
Sullys Hill 1904	North Dakota	1½ sq.m.	Important wild-animal preserve.
Mesa Verde 1906	Colorado	77 sq.m.	Some of most notable and best preserved prehistoric cliff dwellings in the United States.
Glacier 1910	Montana	1,534 sq.m.	Its rugged colourful mountains contain 250 glacier-fed lakes of unusual beauty and 60 small glaciers, the remnants of the mighty ice sheets that ages ago covered this area.
Rocky Mountain 1915	Colorado	378 sq.m.	Typical section of the Rocky Mountains. Most of its mountains have an altitude of from 11,000 to 14,255 feet.
Hawaii 1916	Hawaiian Islands	248 sq.m.	Includes the summit of three famous volcanoes—extinct Haleakala on the Island of Maui and the active volcanoes of Mauna Loa and Kilauea on the Island of Hawaii.
Lassen Volcanic 1916	California	124 sq.m.	Contains only active volcano in continental United States, excluding Alaska, and interesting cinder cones, mud geysers and hot springs.
Mount McKinley 1917	Alaska	2,645 sq.m.	Affords protection to herds of caribou and mountain sheep. Mt. McKinley, its main scenic feature, altitude 20,300 ft., is highest mountain in North America and rises higher above the surrounding country than any other mountain in the world.
Grand Canyon 1919	Arizona	1,009 sq.m.	Contains most spectacular portion of Grand Canyon of Colorado river. This canyon, the world's greatest example of stream erosion, is nearly a mile deep and its widest portion within the park is 18 miles.
Acadia 1919	Maine	15 sq.m.	Only eastern national park, and only one combining sea-coast and mountain scenery.
Zion 1919	Utah	120 sq.m.	Magnificent gorge, Zion canyon, varies in depth from 1,500 to 2,500 feet. Precipitous walls eroded in unusual forms and gorgeously coloured.
Devil's Tower 1906	Wyoming	1,152 ac.	Remarkable natural rock tower 1,200 ft. high of volcanic origin.
Montezuma Castle 1906	Arizona	160 ac.	Protects interesting cliff-dweller ruins.
El Morro 1906	New Mexico	240 ac.	Enormous sandstone rock eroded in the form of a castle upon which inscriptions were carved by early Spanish explorers.
Petrified Forest 1906	Arizona	25,625 ac.	Abundance of petrified coniferous trees of many colours.
Chaco Canyon 1907	New Mexico	21,509.4 ac.	Contains the ruins of many large prehistoric pueblos.
Muir Woods 1908	California	426.43 ac.	Contains one of the most noted coast redwood groves in California.
Pinnacles 1908	California	2,980.26 ac.	Contains many spire-like rock formations 600 to 1,000 ft. high.
Natural Bridges 1908	Utah	2,740 ac.	Three natural bridges, among the largest examples of their kind. The largest is 222 ft. high, with a span of 261 feet.
Lewis and Clark Cavern 1908	Montana	160 ac.	Interesting limestone cavern.

National parks and monuments in order of establishment	Location	Area	Special features
Tumacacori 1908	Arizona	10 ac.	Protects a ruined Franciscan mission dating from the 17th century.
Navajo 1909	Arizona	360 ac.	Numerous well-preserved cliff-dweller ruins.
Shoshone Cavern 1909	Wyoming	210 ac.	Contains a cave of considerable extent.
Gran Quivira 1909	New Mexico	500 ac.	Protects one of most important of earliest Spanish mission ruins of the south-west. Also contains some prehistoric ruins.
Sitka 1910	Alaska	57 ac.	Scene of the massacre of Russians by native Indians in 1802. Contains 16 totem poles of best native workmanship.
Rainbow Bridge 1910	Utah	160 ac.	Unique natural bridge of unusual symmetry in shape of a rainbow, height 309 ft. above the water and span 278 feet.
Colorado 1911	Colorado	13,883 ac.	Contains lofty monoliths, the work of erosion.
Papago Saguaro 1914	Arizona	1,940.43 ac.	Preserves an interesting collection of characteristic desert flora.
Dinosaur 1915	Utah	80 ac.	Deposits of fossil remains of prehistoric animal life.
Capulin Mountain 1916	New Mexico	681 ac.	Huge cinder cone of geologically recent formation.
Verendrye 1917	North Dakota	253.04 ac.	From Crowhigh Butte, Verendrye first beheld territory beyond Missouri river.
Casa Grande 1918	Arizona	472.5 ac.	Some of the most noteworthy relics of a prehistoric people within the limits of the United States.
Katmai 1918	Alaska	1,087,900 ac.	Great scientific interest as an example of volcanism on a large scale, and includes the Valley of Ten Thousand Smokes.
Scotts Bluff 1919	Nebraska	1,803.83 ac.	Many famous old pioneer trails to the West passed over this area.
Yucca House 1919	Colorado	9.6 ac.	Prehistoric ruins.
Fossil Cycad 1922	South Dakota	320 ac.	Interesting deposits of plant fossils.
Aztec Ruins 1923	New Mexico	17.2 ac.	Protects its prehistoric ruins.
Hovenweep 1923	Utah-Colorado	285.8 ac.	Four groups of prehistoric ruins.
Pipe Spring 1923	Arizona	40 ac.	Old stone fort, a relic of pioneer days.
Carlsbad Cave 1923	New Mexico	719.22 ac.	Limestone cavern of extraordinary size and beauty.
Craters of the Moon 1924	Idaho	51,200 ac.	Remarkable fissure eruptions, volcanic cones, craters, lava flows, caves and other volcanic phenomena.
Wupatki 1924	Arizona	2,234.10 ac.	Prehistoric ruins.
Glacier Bay 1925	Alaska	1,164,800 ac.	Tidewater glaciers of the first rank.
Bryce Canyon 1928	Utah	22½ sq. m.	Extraordinary box canyon filled with fantastically eroded and vividly coloured formations.
Grand Teton 1929	Wyoming	150 sq. m.	Embraces the highly picturesque Teton mountains bordering on the Jackson Hole country.
<i>National Military and Other Parks</i>			
Chickamauga and Chattanooga 1890	Georgia and Tennessee	6,534 ac.	Historic significance as Civil War battle-fields.
Antietam Battle-field 1890	Maryland	40 ac.	Scene of one of greatest battles of Civil War.
Shiloh 1894	Tennessee	3,546 ac.	Embraces the battle-field of Shiloh.
Gettysburg 1895	Pennsylvania	2,530.32 ac.	Well-marked scene of famous Civil War battle.
Vicksburg 1899	Mississippi	1,322.63 ac.	Scene of the siege and surrender of Vicksburg in 1863.
Lincoln's Birthplace 1916	Kentucky		Log cabin and part of the farm.
Guilford Courthouse 1917	North Carolina	131 ac.	Scene of a battle of the American Revolution.

National parks and monuments in order of establishment	Location	Area	Special features
<i>National Military and Other Parks</i>			
Moore's Creek 1926	North Carolina	30 ac.	Site of a memorable battle of the Civil War.
Petersburg 1926	Virginia	185 ac.	Scene of campaign and defence of Petersburg during Civil War.
Fredericksburg and Spotsylvania 1927	Virginia		Scene of Civil War battles.
Stone River 1927	Tennessee		Scene of Civil War battle.
<i>National Monuments¹</i>			
Chalmette 1907	Louisiana	17.47 ac.	Memory of battle of New Orleans.
Big Hole Battle-field 1910	Montana	5 ac.	Historic interest as battle-field of Indian wars.
Cabrillo 1913	California	½ ac.	From this point California was first sighted by the explorer Juan Rodriguez Cabrillo in 1542.
Mound City Group 1923	Ohio	57 ac.	Prehistoric Indian mounds.
Fort Wood 1924	New York	2.5 ac.	Site of the Statue of Liberty.
Castle Pinckney 1924	South Carolina	3.5 ac.	Historic fortification.
Fort Pulaski 1924	Georgia	20 ac.	Contains historic fort.
Fort Marion 1924	Florida	18.09 ac.	Fort built by the Spaniards in 1656.
Fort Matanzas 1924	Florida	1 ac.	Relic of the Spanish invasion.
Meriwether Lewis 1925	Tennessee	50 ac.	Contains the grave of Capt. Lewis of the Lewis and Clark expedition.
Fort Niagara 1925	New York	10074 ac.	Commemorates erection of cross by Father Millett in 1688.
Fort McHenry 1925	Maryland	46.75 ac.	Here the "Star Spangled Banner" was written.
<i>National Monuments²</i>			
Gila Cliff Dwellings 1907	New Mexico	160 ac.	Numerous cliff dwellings.
Tonto 1907	Arizona	640 ac.	Cliff-dweller ruins.
Jewel Cave 1908	South Dakota	1,280 ac.	Interesting limestone cavern.
Wheeler 1908	Colorado	300 ac.	Interesting examples of erosion and volcanic action.
Mount Olympus 1909	Washington	299,370 ac.	Summer range and breeding ground of the Olympic elk.
Oregon Caves 1909	Oregon	480 ac.	Extensive limestone caverns.
Devils Postpile 1911	California	800 ac.	Spectacular mass of hexagonal basaltic columns like an immense pile of posts.
Walnut Canyon 1915	Arizona	960 ac.	Cliff-dweller ruins.
Bandelier 1916	New Mexico	22,075 ac.	Great number of cliff-dweller ruins.
Old Kasaan 1916	Alaska	38.3 ac.	Covers abandoned Indian village containing totem poles and other historic objects.
Lehman Caves 1922	Nevada	593.03 ac.	Limestone caverns.
Timpanogos Cave 1922	Utah	250 ac.	Limestone caverns.
Bryce Canyon 1923	Utah	7,440 ac.	Box canyon filled with fantastically eroded and vividly coloured pinnacles. This area was given national park status in 1928.
Chiricahua 1924	Arizona	4,480 ac.	Interesting rock formations.
Lava Beds 1925	California	45,967 ac.	Interesting ice caves and the site of a battle of the Modoc Indian war in 1873.
White Plains Battle-field 1926	New York		Memorial Tablet to indicate position of Revolutionary Army under command of General Washington.

¹Administered by War Department.²Administered by Department of Agriculture.

Complete Conservation.—The national parks and national monuments are the only areas in the United States where the native fauna, flora and natural phenomena are given absolute protection, in an endeavour to preserve for future generations bits of American scenery and wild life as they were when the early pioneers first saw them. The introduction of exotic animals or plants is guarded against. The complete protection afforded game species within these reservations serves an important economic purpose in that, by providing a safe retreat, especially during the breeding season, these animals are given an opportunity to increase to the point of overflow to adjacent territory, where they may be hunted or trapped under State laws.

Recreational Uses of National Parks.—Between 1916 and 1928, travel to the parks and monuments administered by the national park service increased from 356,097 to 3,024,844, and recreational facilities were provided to care for these visitors. Hotel and comfortable lodge accommodations are available and free public camp grounds have been provided by the Government. In some of these camp grounds housekeeping cabins may be rented and cafeteria service is available. Water, electric lighting and sanitary conveniences are furnished, as well as firewood and in some places open fireplaces for cooking. Transport service is provided for those visiting the parks by train, and saddle horses and pack outfits for those wishing to explore and camp in outlying portions of the parks. Roads are provided for motorists and trails for horseback riders and walkers. Where winter sports can be enjoyed, toboggans, ski courses and skis, sleighs and snow-shoes are to be had. The streams and lakes are stocked with game fish, and camera supplies are obtainable. Pamphlets descriptive of the various parks, giving information regarding their recreational attractions and the facilities provided for visitors may be secured from the National Park Service.

Private Lands Within Park Boundaries.—A problem that has caused considerable difficulty in administering the national parks to the best advantage is the existence of private lands within their exterior boundaries. With the exception of the Yellowstone national park and Hot Springs, which were created before any of the lands desired for original inclusion had been settled, practically all of the national parks contain *bona fide* private lands, which are given the same protection accorded private lands elsewhere. During the past 13 years continued efforts have been made to secure such private holdings for donation to the United States. Private contributions amounting to \$150,000 have been secured to purchase magnificent stands of *Sequoia gigantea* and other private holdings in Sequoia national park alone; they were turned over to the United States for addition to the park. The only appropriation made by Congress before 1927 to purchase lands for park purposes was in 1916, when \$50,000 was appropriated to purchase an important stand of big trees in the giant forest of Sequoia park. This appropriation was supplemented by \$20,000 contributed by the National Geographic Society. In 1927, however, Congress recognized the importance of eliminating private holdings, and appropriated \$50,000 for the purchase of privately owned lands within the boundaries of any national park, to be expended only when matched by equal amounts of donations from other sources and which are available for the same purpose. A similar appropriation was made in 1928.

Although not reserved for economic reasons, and not open to commercial development, the national parks, and to a lesser extent the national monuments, have a very decided value to the United States and this value lies in their complete protection from commercialization. Their forests, left standing, are of immeasurable benefit to nearby communities through affording protection to the watersheds of important streams, thus often preventing floods and the droughts that may follow in their wake. From a strictly financial standpoint, they bring in large revenues each year. During 1928 the revenues derived from franchise fees, automobile licences and other sources amounted to \$808,255.81, and these funds were turned into the treasury of the United States to be available for appropriation for the purposes of the Government. In 1916 park revenues amounted to only \$177,470.69. Of still greater economic importance is the part the

parks play in offering to American travellers objects of such general scenic interest as to lead them to "see America first," in this way keeping at home millions of dollars which would otherwise be spent abroad, and which spent in the United States in travel brings increased taxes into the Federal Treasury.

(S. T. M.; I. F. S.)

NATIONAL PARKS HIGHWAY (Northwest Trail), a highway from Chicago to Seattle, Wash. It is paved through Illinois, Wisconsin and most of Minnesota; the balance is mostly gravel with short graded stretches. It is 2,532 m. long and passes just north of the Yellowstone National Park and south of Glacier National Park. It serves, among others, the cities of Fargo, N.D., Billings and Helena, Mont., and Spokane and Seattle, Wash.

NATIONAL PARK TO PARK HIGHWAY, an American highway bringing into connection all of the national parks (*q.v.*) of western United States and about 4,500 m. long. It is a most wonderful scenic road, circling the Rocky mountains, Sierra Nevada and Pacific coast ranges. The roadway is partly paved, improved or graded. Among the cities touched by it are Seattle, Wash., Portland, Ore., Yreka, Redding, Sacramento, San Francisco and Los Angeles, Calif., Kingman and St. Johns, Ariz., Zuni and Liberty, N.M., Pueblo and Denver, Colo., Cheyenne, Casper and Cody, Wyo., Great Falls and Libby, Mont., and Spokane, Wash.

NATIONAL PROVINCIAL BANK LIMITED. This great British banking institution, one of the "Big Five" (*see* BANKS, HISTORY OF), has over 1,200 branches in London and the provinces. The amalgamation movement wrought great changes in the English banking system, and the National Provincial bank has been closely identified with it, particularly during the period from 1918 to 1924. The most important amalgamation effected by the bank took place in 1918, when it took over the Union of London and Smiths bank, Limited. In the same year, the business of the Bradford District bank Limited was acquired. The Sheffield Banking company Limited was absorbed in 1919, the Northamptonshire Union bank Limited in 1920 and the Guernsey Banking company Limited in 1924. A number of private banks also were absorbed; in 1920 and 1924 respectively Coutts and Co. and Grindlay and Co. Ltd. became affiliated, though both organizations continue business in their own names.

The parent bank was founded in 1833. At the time of its establishment, the creation of joint stock banks had but recently been legalized, and any such banks conducting business within 65 miles of London were denied the right of issuing notes, at that time a lucrative privilege. It was decided to confine the banking activities of the new company to the provinces, thereby securing the right of note issue, and to maintain control from an administrative office in London. The first office was opened at Gloucester on January 1, 1834, and by 1838 there were 60 offices open. After some years the directors decided that the advantages of conducting business in London would outweigh those of retaining their note issue. Accordingly, business commenced in 1866 in Bishopsgate, London. At that time the bank was given a seat in the London Bankers' clearing house, a privilege hitherto withheld owing to the antagonism of the private banks to their joint stock rivals. In 1880 the institution was registered as a limited liability company.

The growth of the National Provincial bank is shown in the following figures:—

	Paid up capital and reserves	Deposits	No. of offices
	£	£	
1870 . . .	1,513,373	15,734,999	133
1914 . . .	5,000,000	74,916,017	444
1927 . . .	18,958,832	273,597,202	1,217

On December 31, 1927, the accounts of the National Provincial bank disclosed a balance of current, deposit and other accounts amounting to over £273,000,000 and the manner in which these funds were utilized will be seen from the following summary of the balance sheet as at that date.

Whilst the bulk of its resources is employed in various interest-earning capacities, the bank keeps available in the form of cash in hand and balance at the Bank of England the substantial sum of £32,000,000. The item, money at call and short notice, of over £21,000,000, represents advances to the bill brokers and discount houses, chiefly against deposit of treasury bills or first class bank bills. These advances, as their name indicates, are very liquid and are repayable at short notice. Bills discounted include a large proportion of treasury bills and the item investments includes over £30,000,000 of British Government securities.

A large portion of the bank's funds is employed in advances to customers. Very considerable sums are borrowed from banks by trading and industrial undertakings and by private individuals, the bank advance occupying an important place in the economic structure of the country. (L. C. M.)

NATIONAL RESERVE. A body of men, who having served in any of the British military forces, registered with County Associations for service in time of grave national emergency. The original title in 1910 was "Veteran Reserve" but this was changed in 1911 and the late Lord Roberts, V.C., was appointed "Colonel of the National Reserve." At the outbreak of the World War the whole of the reserve were accepted in various capacities.

NATIONAL ROOSEVELT MIDLAND TRAIL, an American highway connecting Newport News, Va., and Los Angeles, Calif., traversing about 3,550 miles. It passes over the Appalachian mountains on the eastern end, through the farming districts of the Mid-West, across the plains, through one of the most mountainous regions of the Rockies, and over Westgard Pass into California at the foot of the Sierra Nevadas. In this section, for 100 m. on either side of Mt. Whitney, the highest American peak, there is a view of saw-tooth, snow-capped ranges. From Newport News to Kansas City, Mo., the roadway is paved, hard and improved; beyond it is partly paved, hard, gravelled or graded. Other localities served by the route are Richmond, Va., Charleston, W.Va., Lexington, Ky., Vincennes, Ind., St. Louis, Mo., Topeka, Kan., Denver, Hot Sulphur Springs and Grand Junction, Colo., Salt Lake City, Utah, McGill, Nev., and Big Pine and Olancho, Calif.

NATIONAL SAVINGS. Estimates of aggregate national savings may proceed upon two quite distinct bases:

- That amount which is definitely saved out of the national income from current consumption for capital purposes.
- The net additions to national resources.

If a man spares out of his income £200 to build a garage, he has, in the first sense, clearly saved £200, irrespective of the fact that a greenhouse worth £100 has been burnt down by accident during the year. But in the second sense his total resources have only increased by £100. It is clear, therefore, that a nation may be making handsome savings from its current production, but if existing assets are falling into disuse or obsolescence and losing their productive power, the net addition to national resources is not as great as it might otherwise have been. It may be said that this is sufficiently covered if, before savings are reckoned, proper provision is made for the upkeep of existing assets, but, in fact, long-period obsolescence, except in going concerns, is not usually specifically provided for. If estimates of national wealth are made on the same principle, at two different dates, the difference between them represents roughly the addition

to national resources, provided there has been no change in the purchasing power of money, or the rate of interest by which capitalization is computed, in the meantime. If either of these factors is present, the same assets may present a very different money valuation, or conversely the same money valuation may hide a real difference in physical assets. Thus between the years 1885 and 1895 the national capital, measured in the same way, increased by only 63 millions annually, whereas between 1895 and 1905 it increased by 237 millions annually.

Estimates of national savings are extremely difficult to compile, because they are necessarily partial blends of two distinct things—one the value of objective things and the other the value of titles to objective things. Thus it might be thought, when a new company is floated with a capital of £500,000 fully subscribed by the public, that this represents so much actual saving. If, however, the company acquired existing factories which originally cost £250,000, all that may have happened is that the subscribers have sold out £500,000 worth of securities to make the subscription, the owner of the factories gives up the property, receives the money and reinvests it indirectly in the securities so given up. There has been a change of values of existing wealth on its exchange, but no addition to the real wealth.

Estimates of savings made by way of deducting a large total, such as total consumption from total income, are open to a large risk of error for two reasons; first, because the totals are both large by contrast with the difference sought, and a very small percentage of error in either total (or both) will be a very large error, proportionally, in the difference sought. Secondly, there is a great difficulty in determining the value of consumption goods as distinguished from capital goods.

Past Estimates of British Savings.—In 1880 Mulhall estimated the savings of the United Kingdom as 40 millions per annum from 1820 to 1840; 80 millions from 1841 to 1860, and 120 millions from 1861 to 1880. Baxter had put the ten years' average 1855 to 1865 at 124 millions. In 1907 the official *Census of Production Reports* estimated from 170 to 190 millions sterling as the value of production available for new capital investment within the United Kingdom. It must not, however, be overlooked that the new investments do not constitute as a whole a net addition to capital values. Even in cases in which plant, machinery, buildings, etc., are maintained in good physical condition, their value may be reduced owing to the fact that changes in the requirements of the community are in progress, and that the methods of production are undergoing continuous modification, so that obsolescence destroys the value of capital, even though its physical condition be maintained. There is further some apparently new investment which does not, in reality, correspond to extensions of the capital of the community. The annual sum assigned for wear and tear and replacement is only in part dissipated in current repairs and renewals. The reserve funds of individual businesses, provided out of the total, are invested either outside of, or in the businesses themselves, and are to a large extent designed to provide for the ultimate substitution of fresh forms of capital for the capital now existing, rather than for the current maintenance of such capital. But, if a vessel is written off over 25 years at 4 per cent per annum, the fund ostensibly provides no increase in assets or saving.

Recent Estimates.—In their Analysis in *National Income 1924* (1926), Professor Bowley and Sir Josiah Stamp say:—

"In 1911 the total saving was estimated roughly as £330 millions, of which £230 millions were invested at home, £100 millions abroad; hence, since home-produced income was about £1,900 millions, savings for home use amounted to about 12 per cent. of that income. Total savings are even more difficult to estimate in 1924, but if we adopt the figures finding most acceptance, £450 millions is a minimum and £500 millions is a maximum. These totals include £135 millions for overseas investment, so that the amount allotted to home investment is about £350 millions, not quite 10 per cent. of home-produced social income (i.e., aggregate income less transfers). Total savings expressed as a proportion of total social income was on the same estimates, 16 per cent. in 1911 and 12 or 13 per cent. in 1924."

The amount of British national savings has recently been investigated by the Colwyn Committee, who found as follows:

"Until very recently the tendency has been to put national savings during the post-war depression very low indeed, but more mature consideration has seemed to justify an estimate of something like £450 millions to £500 millions, and a figure in this range of magnitude has won some acceptance.

"We are disposed to think that a figure of £450 millions to £500 millions represents the best estimate that can be made with the data available."

The equivalent of pre-war savings of £350 millions to £400 millions would, at the mean, be some £650 millions, when account is taken of the higher prices and increased population. Thus, while nominal savings have increased, real savings exhibit a decline which may amount in present money values to something like £150 millions to £200 millions.

The only detailed estimate before the Colwyn Committee was given by Dr. W. H. Coates for 1924, as follows:—

	£ millions
Internal new issues for investment in the United Kingdom	89
Internal new issues for investment abroad	135
Addition to National Savings Certificates	3
Increase in Treasury holdings of Bonds tendered in payment of Death Duties	9
Investments sold by the banks	35
New Houses	35
Profits not distributed by companies and private traders but invested in own businesses; and miscellaneous	194
	500

Dealing with the character of British savings, W. T. Layton gave the following table analysing new issues of 1913 and of 1921 to 1923 as tending to confirm the "general expectation that the public is playing for safety."

New Home Issues for Industrial Purposes

	Ordinary (£ millions)	Preference (£ millions)	Debenture (£ millions)	Total (£ millions)
1913 . . .	20.0	20.6	13.0	53.6
1921 . . .	17.9	14.4	56.8	89.1
1922 . . .	12.3	12.9	50.4	75.6
1923 . . .	14.0	15.2	37.8	67.0

Evidence was given that in the five years before the World War there were £482 millions of foreign investments and £381 millions of colonial investments; in the five years since the war there have been £145 millions of foreign investments, and £321 millions of colonial investments.

Working-class savings, in the view of the committee, form a small percentage of the total savings by individuals. There has evidently been a decline in saving in the income tax paying classes as a whole, but there is no clear evidence for its allocation.

Generally, they concluded that the falling off in the national savings, equal to £150 millions or £200 millions at the 1927 level of prices, gave "ground for anxiety but not for pessimism."

An estimate of British national savings more recent than that of the Colwyn Committee is given by the Liberal Industrial Enquiry, 1928, as follows:—

1. Under the influence of the Government (Central and Local), including repayment of Government external debt, the Road Fund, Telephones, and Local Loans Fund, and capital expenditure by Local Authorities £ 90,000,000
 2. Through the accumulation of reserves by the retention of profits within existing businesses 195,000,000
 3. Dwelling houses and their equipment, otherwise than by Public Authorities or under other headings 65,000,000
 4. Through increased Bank loans and advances, etc. (net) 25,000,000
 5. Through the New Issue Market for new capital expenditure at home not covered by previous headings and excluding exchanges of existing capital through the machinery of the New Issue Market 25,000,000
 6. Through the New Issue Market and the Stock Exchange for investment abroad (net) 100,000,000
- 500,000,000

A comparison of the two estimates brings out the difficulties of formulating estimates of this kind.

The Main Springs of National Savings.—It will have been seen from the foregoing analysis that the aggregate accumulation is to a marked extent dependent upon the undistributed profits of industrial concerns. This has great importance having regard to the sensitiveness of personal motives for saving to the influences of taxation or other causes. These funds are far less influenced by high or low rates of tax or high or low rates of interest, than any other section of national savings. It is true that the *scope* for accumulations may be rather less with high taxation, but they do not immediately attract supertax or death duties and the average board of directors is entirely uninfluenced by such considerations. There is an increasing practice of building up a solid and sound position by secret reserves and a desire to establish a policy of stable dividends. Reserves can be made in the first instance with the ostensible object of equalization of dividends, but they often ultimately find themselves solidified in investments or extensions of the business.

The second great source of saving, paradoxically enough, is taxation. High taxation levied to maintain a large sinking fund for the repayment of an enormous national debt is a very direct contribution towards the accumulated fund. When debt is paid off in the form of redemption of war-loan it is almost certain that the funds so received are not spent as income by the holder of the redeemed war loan but are reinvested. There is thus a constant stream of money withdrawn as taxation going into new objective forms.

High taxation with a sinking fund is, therefore, a forcible contribution to the national savings. For example, the Liberal Industrial Enquiry reported:

"The proposal of the Colwyn Committee that the Sinking Fund should be increased to £100 millions per annum would, therefore, obviously—although apparently burdensome on taxation—greatly increase the national resources for investment purposes. If they merely have the effect of increasing the volume of British loans abroad, it is doubtful whether the game is worth the candle, but if they are really available for the development of home resources then the apparent extra burden might easily be offset by increased productivity."

The third source is the aggregate of the very numerous accumulations of small sums put aside by the working classes. The improved standard of life and the social provision made for special circumstances of distress and for pensions, etc., have given greater free margin than formerly existed for small accumulations by way of the Post Office, National Savings Certificates, Industrial Insurance and Building Societies. The situation created by the war in the scarcity of houses has brought about, almost compulsorily, a new practice of house-ownership.

Taxation and National Saving.—The chief cause, inimical to high accumulation of capital, is the heavy taxation on the higher grades of income and estates. Nothing is here said as to the justice, viewed merely as a taxation burden upon the individual, of such progressive scales. In the past a very large part of the total savings came from the unused wealth of the rich. It has been said that the 19th century tacitly acquiesced in the great disparity in the distribution of wealth, on the understanding that the very wealthy did not use their money but "turned it in" again for the benefit of the community. If very large sums are absorbed from the relatively few wealthy for distribution amongst the many as pensions and for other social purposes, then the duty of accumulation cannot be discharged to the same extent by the few, but devolves upon the many. Sir Josiah Stamp has said: "On grounds which can be well defended, very large sums are taken from the higher incomes. The effect upon the range of net incomes of the nation is that they are much more evenly distributed than they would otherwise be. But the top portion of a big income used to contribute materially towards saving. To-day you take away that top portion for taxes. The great mass of the people benefit by this system, for, if it did not exist, they would have to bear a greater proportion of the national expenditure and have a smaller net income."

The Liberal Industrial Enquiry agreed that the pressure of taxation had reduced the savings of the rich and well-to-do far more than it had increased the savings of wage-earners "so that the amount annually available for investment has decreased by something like 150 to 200 million £." Savings certificates reached some 475 millions, including accumulated interest, by 1926. Post Office Savings Bank deposits rose 116 million £ in six years; co-operative capital increased by 57 millions in 12 years; Friendly Societies 47 millions in 13 years; Industrial and Provident Societies by 135 millions, and Building Societies 84 millions in 14 years. These figures indicate a contribution of from 80 to 100 millions a year from small investors and it is notorious that the average holdings in big industrial concerns are very small, and that the working classes are extending their interests in industry.

National Savings in Germany.—Dr. Helfferich's computations for the years immediately before the war, 1908 to 1913, led to an estimate of 8 to 8½ milliards of gold marks (£400 to 425 millions) as the annual national saving. A variety of estimates have been made, some of them rather arbitrary. Prof. Prior (*Kreditpolitik-Aufsätze und Reden*) gives 3 to 4 milliard marks in 1924 and 1925; Prof. Hirsch (*Magazin der Wirtschaft*), 5 milliards for 1925; the *Frankfurter Zeitung*, 7½ milliards for 1926 and 9 for 1927; the *Reichskreditgesellschaft*, 6.4 for 1925, 6.3 for 1926 and 7.6 milliards for 1927. The hypothetical character of these estimates must be emphasized.

See: Report of the Colwyn Committee on Taxation and the National Debt; Report of the Liberal Industrial Enquiry; A. L. Bowley and J. C. Stamp: *National Income 1924* (1926). (J. S.)

UNITED STATES

When the value of money remains constant, in other words when the price-level does not change, it is usually a simple matter to measure the savings of an individual during any given interval of time. All that is necessary is to subtract the net value of his wealth at the beginning of the period from the net value of his wealth at the end of the period. The difference represents his savings during the period.

There are two logical ways of defining the term national savings: (1) The sum of the individual savings of all the inhabitants of the nation. (2) The increase in the physical, institutional, and mental wealth of the nation plus the increase in the value of its claims against other nations.

The National Aggregate of Private Savings.—It is not statistically practicable to ascertain the savings of each individual or of each family in the United States and then add these sums together to obtain the aggregate of private savings for the nation. In fact, the only type of private savings for which any records are available is for the savings of corporations as shown by their respective accounting systems.

At present, every corporation in the United States is required to report annually to the Bureau of Internal Revenue both its net income and the amount of dividends which it has paid out during the year. Obviously, by subtraction, one can arrive at the amount of saving shown by its corporate accounts. The aggregate of savings for all corporations, as indicated by the reports for the various years, are as follows: 1922, \$2,530,484,240; 1923, \$3,465,145,765; 1924, \$2,456,328,887; 1925, \$4,126,908,269; 1926, \$3,565,146,340.

Could we accept these figures as valid, we would have covered one important field of national savings. Unfortunately, however, since the validity of the reported savings depends upon the accuracy of the estimates of the values of property owned by the corporations at the beginning and at the end of the year, and since doubtless, in very many instances, the valuation placed by the corporate accountant upon the property of his corporation bears but little relation to the realities of the case, the above figures, indicating the total volume of corporate savings, must be taken with many grains of salt.

Were the data available, a simple method of measuring the total of individual savings would be to find the value of all the wealth belonging to individuals at the beginning of the year, do the same for the end of the year, convert these aggregates to dollars of equal purchasing power, and, finally, subtract the corrected figure for Jan. 1 from the corrected figure for Dec. 31. For many

categories of individual wealth, the data at hand are, however, so scanty that estimates made in this manner are necessarily subject to large possible margins of error. The only field in which there appears to be hope of securing worth while results by this method of computation is in the calculation of the volume of corporate rather than of individual saving.

Each corporation reports to the U.S. Bureau of Internal Revenue annually the amount of its funded debt, and the "fair" market value of its stock. The total value of corporate wealth is roughly represented by the combined value of the corporate bonds and corporate stocks. If we assume that the bonds are, on the average, worth par (an assumption not wildly in error), we can readily arrive at the change during the year occurring in the value of all corporations. Since, during the period covered by these reports, the price-level has fluctuated but slightly, estimates of corporate savings made in this manner are not without value. Figures for corporate savings, obtained in the manner just described, follow:—

Increase in Millions of Dollars

Period	Face value of bonds	Face value of stocks	Value of stocks and bonds
	\$	\$	\$
June 30, 1923 to June 30, 1926	9,096	17,512	26,608
Average annual increase for three-year period	3,032	5,837	8,869

From the figures just presented, it appears that the corporations of the United States have recently been increasing in value to their owners at the average rate of about \$9,000,000,000 per annum. Of course, a considerable proportion of this growth in value may represent not any increase in the volume of tangible property held by corporations, but merely an undue degree of optimism concerning the future course of corporate earnings.

Such scanty evidence as is available indicates that nearly half of the total volume of saving in the United States is done by business enterprises. (See *The Journal of the American Statistical Association*, Dec. 1922, pp. 458-470.) As yet, however, most agricultural undertakings, much of the mercantile business and many of the smaller enterprises in other lines have not been taken over by corporations; hence the volume of corporate savings is probably not over one-third of the total national savings.

It is far from easy to estimate the total extent of individual saving. If one attempts to obtain the figure from estimated aggregates of individual wealth one quickly discovers that, for most types of wealth, data are very incomplete.

National Saving from the Social Standpoint.—From the social standpoint, a nation's savings during any period are comprised of increases in: (1) The stock of wealth in the form of material goods used either for production or consumption by the nation or its inhabitants. This type of saving evidently includes improvements in the land itself as well as additions to the stock of buildings and of movable goods. (These claims are equities in a stock of tangible goods located abroad which either have been produced or which it is expected will be produced in the future.) (2) Valuable claims against other nations or their inhabitants.

Social Savings during the 10-year Period 1909-1918

Calendar year	Millions of dollars having a value equivalent to that of 1913
	\$
1909	5,231
1910	5,509
1911	4,289
1912	5,268
1913	4,880
1914	4,140
1915	7,381
1916	11,401
1917	7,162
1918	1,196

Corresponding estimates for more recent years are not available.

A Roughly Estimated Index of the Fractional Increase During a Decade in the Actual Wealth of the People of the United States

Kinds of wealth	Beginning of period		End of period		Multiplier	Product in millions.

						1.0000	1.38

(3) The accumulated store of scientific knowledge and organization of productive forces. (4) The productive power of the inhabitants resulting from education, hygienic measures, etc.

A confessedly rough estimate made by the present writer in *The Journal of the American Statistical Association* for Dec. 1922, shows the social savings of the nation to have amounted to about one-seventh of the total income of the nation during the years 1909 to 1918 inclusive. When translated into terms of dollars of 1913 value the amounts estimated to have been saved annually are as in table on page 161.

In the same study, appears an estimate along this line, on the basis of sample data, of the increase in the value of the wealth of the United States during the nine or ten year period ending approximately in 1918. This estimate indicates that the nation's wealth increased by about one-third in that period of nine or ten years.

A corresponding estimate for the last decade appears in the accompanying table.

According to the indications cited in the table, the wealth of the people of the nation increased by approximately 38% during the decade ending in 1926 or 1927. Apparently the American people are still tending to save a very considerable fraction of their total annual income—a fraction amounting to at least a tenth and possibly as much as a seventh of the whole. This percentage is, of course, subject to a wide margin of error. Substantial gains in the individual items entering into the total are, however, so general as to convey the distinct impression that the proportional rate of increase in the aggregate during this decade has been at least as rapid as that characterizing the decade immediately preceding.

(W. I. K.)

NATIONAL WORKSHOPS (in French, *Ateliers Nationaux*), the term applied to the workshops established to provide work for the unemployed by the French provisional government after the revolution of 1848. (The term is also incorrectly applied to the proposed *ateliers sociaux* of Louis Blanc [q.v.], state-supported co-operative productive societies.) The revolution was

both preceded and followed by a severe financial and industrial crisis which rendered the problem of unemployment in Paris very acute. The provisional government under the influence of one of its members, Louis Blanc, and on the demand of a deputation of Parisian workers, passed a decree (Feb. 25, 1848) which contained bold promises assuring relief from the extreme conditions then prevailing. Moreover, this relief was to be immediate, effectual and universal. The following is an extract from the decree:—

"The provisional government of the French Republic undertakes to guarantee the existence of the workmen by work. It undertakes to guarantee work for every citizen."

For the carrying out of this decree, Louis Blanc wanted the formation of a ministry of labour, but this was shelved by his colleagues who, as a compromise, appointed the "Luxembourg" labour commission, under the presidency of Louis Blanc, with power of inquiry and consultation only. The carrying out of the decree of Feb. 25 was entrusted to the minister of public works, M. Marie, and various public works were immediately started. These included clearing the trench of Clamart and conveying the earth to Paris for the construction of a railway station on the chemin de fer de l'Ouest; construction of the Paris terminus of the Paris-Chartres railway; improvement of the navigation of the Oise; extension of the Sceaux railway to Orsay.

Those applying for work far exceeded in number the jobs available. There was no effective administrative service and no real desire on the part of the government to make the experiment a success. The disorder and waste were amazing.

Owing to the increase in the number of those claiming work or relief, disorganization set in, and both the bureaux and the maires became the centres of disturbances, those in charge of the offices being unable to control the crowds. As a consequence M. Marie commissioned Émile Thomas, a chemist, connected with the École Centrale, to reorganize the works. When Thomas took the work in hand on March 5, the number of unemployed had increased to 14,000 in addition to some 4,000 or 5,000 employed on public

works, and it was steadily on the increase. On March 16 the daily pay of the workmen who were not working was reduced to one franc; work was guaranteed for at least every other day, in which case the pay was to be two francs for the day.

The National Assembly had in the meanwhile been elected, and met on May 4. The Executive Commission was elected a few days later; Louis Blanc was excluded, but all the other members of the provisional government were on it. Blanc renewed his motion for a ministry of labour; this was rejected. The dispersal of the *emete* of May 15 freed the Assembly from fear of the revolutionary clubs, and on May 15 Thomas received instructions to dismiss all unmarried men under 25 years of age who would not enlist in the army, all men who could not prove six months' residence in Paris, and all who refused offers of private employment. Piece-work was to be established instead of time-work, and men were to be prepared to be drafted into the provinces. The protests of Thomas held this plan up, but he was removed from office on May 26 and on June 20 the proposals were approved, and the sequel was the insurrection of June 23 and following days (*see FRANCE: History*).

NATIONS, LAW OF: *see* INTERNATIONAL LAW.

NATROLITE, a mineral species belonging to the zeolite group. It is a hydrated sodium and aluminium silicate with the formula $\text{Na}_2\text{Al}_2\text{Si}_2\text{O}_{10} \cdot 2\text{H}_2\text{O}$, and containing sodium (Na_2O , 16.3%). "Needlestone" or "needle-zeolite" are other names, alluding to the common acicular habit of the crystals, which are often very slender and are aggregated in divergent tufts. Larger crystals have the form of a square prism terminated by a low pyramid: the prism angle being nearly a right angle ($88^\circ 45'$), the crystals are tetragonal in appearance, though actually orthorhombic. There are perfect cleavages parallel to the faces of the prism. The mineral also often occurs in compact fibrous aggregates, the fibres having a divergent or radial arrangement. Natrolite is usually white or colourless, but sometimes reddish or yellowish. The lustre is vitreous, or in finely fibrous specimens sometimes silky. The spec. grav. is 2.2, and the hardness $5\frac{1}{2}$. The mineral is readily fusible. It is decomposed by hydrochloric acid with separation of gelatinous silica.

NATTIER, JEAN MARC (1685–1766), French painter, was born in Paris in 1685, the son of Marc Nattier, a portrait painter, and of Marie Courtois, a miniaturist. He received his first instruction from his father, and took the first prize at the Paris Academy at the age of fifteen. He refused to study at the French Academy in Rome, and in 1715 went to Amsterdam, where Peter the Great was then staying. There he painted portraits of the tsar and the empress Catherine, but declined an offer to go to Russia. Between 1715 and 1720 he painted the "Battle of Pultawa," for Peter the Great, and the "Petrification of Phineus and of his Companions," which led to his election to the Academy. The financial collapse of 1720 caused by the schemes of Law all but ruined Nattier, who was obliged to turn to portraiture. He became the painter of the artificial ladies of Louis XV's court. The most notable examples of his straightforward portraiture are the "Marie Leszczinska" at the Dijon Museum, and a group of the artist surrounded by his family, dated 1730. He died in Paris in 1766.

Among his pictures are the "Magdalen" at the Louvre; "La Camargo" and "A Lady of the Court of Louis XV." at Nantes; the "Head of a Young Girl" at Orléans and "Mme. de Pompadour" at Versailles. The Versailles Museum owns an important group of two ladies, and the Dresden Gallery a portrait of the "Maréchal de Saxe." In the Wallace collection are "The Comtesse de Dillières," "The Bath (Mdlle de Clermont)," "Portrait of a Lady in Blue," "Marie Leszczinska" and "A Prince of the House of France." Nattier's works have been engraved by Leroy, Tardieu, Lépicier, Audran, and other noted craftsmen.

See "J. M. Nattier," by Paul Mantz, in the *Gazette des beaux-arts* (1904); *Life of Nattier*, by his daughter, Madame Tocqué; *Nattier*, by Pierre de Nolhac (1904, revised 1910); and *French Painters of the XVIIIth Century*, by Lady Dilke (London, 1899).

NATURAL BRIDGE, a small village of Rockbridge county, Va., in the western part of the State, 179 m. by rail W. of Richmond, and about 16 m. S.E. of Lexington, the county seat. It is served by the Chesapeake and Ohio and the Norfolk and Western railways. In the vicinity of the village, which is about 1,500 ft. above sea-level, is the great natural curiosity from which it derives its name—a bridge of natural rock 90 ft. long and from 50 to 150 ft. wide, which spans Cedar Creek at a height of 215 ft. above that stream. It consists of horizontal limestone strata, and is the remains of the roof of a cave or underground tunnel through which the creek once flowed. It is crossed by a public road. In the village are magnesia and lithia springs and a saltpetre cave.

NATURAL GAS, the name given to the inflammable gas occurring in petroliferous formations. The occurrence of natural gas is wide-spread, both geographically and geologically. Geographically, natural gas is produced in: (1) United States—Alaska, Arkansas, California, Colorado, Illinois, Indiana, Kansas, Kentucky, Louisiana, Michigan, Missouri, Montana, New Mexico, New York, Ohio, Oklahoma, Pennsylvania, South Dakota, Tennessee, Texas, Utah, West Virginia and Wyoming; and (2) Canada—Alberta, New Brunswick, Ontario and Saskatchewan. The more important fields in which natural gas is produced in the United States are described as: (a) Appalachian; (b) Lima-Indiana; (c) Mid-continent; (d) Gulf coast; (e) Rocky mountain; and (f) California. Geologically, these deposits of natural gas are as follows: (a) Appalachian field, from the Carboniferous, Devonian, Silurian, Ordovician and Cambrian systems; (b) Lima-Indiana field, mostly from the Trenton formation of the Ordovician system; (c) Mid-continent field, mainly from the Carboniferous system; (d) Gulf coast, from the Tertiary and Cretaceous systems; (e) Rocky mountain, from Carboniferous, Tertiary, Cretaceous and Jurassic systems; and (f) California, throughout the entire Tertiary system including Eocene, Oligocene, Miocene and Pliocene formations.

Chemical Composition.—Natural gas is, for the most part, composed of the hydrocarbons of the paraffin series, carbon dioxide, nitrogen and helium. However, its composition varies considerably in the different fields. Natural gas of the eastern or Appalachian field is almost entirely made up of the hydrocarbons of the paraffin series. Natural gas of some parts of Kansas, Oklahoma and Texas is very high in nitrogen and relatively high in helium content. Some of the natural gas of the Pacific coast contains large percentages of carbon dioxide. Natural gas in a few districts contains hydrogen sulphide and organic sulphur compounds. The paraffin hydrocarbons found in natural gas are methane, ethane, propane, butane, pentane, hexane, heptane and octane. The first four named hydrocarbons are gaseous under ordinary conditions of temperature and pressure. The last four hydrocarbons are normally liquid at atmospheric temperature and pressure, and are the main components of natural petrol gas (gasolene).

The following is a tabulation of typical analyses of commercial natural gas:—

Cities	Methane	Ethane	Carbon dioxide	Nitrogen
Pittsburgh	84.7	13.7	..	1.6
Cleveland	80.5	18.2	..	1.3
Cincinnati	79.8	19.5	..	0.7
Columbus	80.4	18.1	..	1.5
Bartlesville	92.4	3.1	1.4	3.1
Kansas City	84.1	5.7	0.8	8.4
Fort Worth	51.5	10.2	..	38.3
Los Angeles	77.5	16.0	6.5	0.0
Little Rock	96.7	..	1.0	2.3
Monroe, La.	94.69	2.80	0.2	2.31

(The data contained in this tabulation, with the exception of those relative to Monroe gas, have been taken from *Technical Papers* No. 100 and 158 of the U.S. Bureau of Mines. The information regarding Monroe gas has been furnished by J. A. Bechtold, secretary, Standard Oil Company of Louisiana.)

"Dry" and "Wet" or "Casinghead" Natural Gas.—Natural gas gasolene, as vapour, does not exist in recoverable quantities

in all natural gas. Stable natural gas gasoline is made up of the hydrocarbons butane, pentane, hexane, heptane and octane. The notable instances of fields of natural gas production wherein gasoline vapours do not occur are: Ft. Smith, Ark.; Shallow Sand, Desoto parish, La.; Elm Grove, La.; east Texas; Murraysville Sand, Pa., and Upper Oriskany Sand, Pa. (6,822 ft.). Natural gas is commonly described as "dry" and "wet" or "casinghead" gas. These descriptions are relative. Dry gas is usually produced from gas wells containing natural gas gasoline vapours, recoverable as liquid, to the extent of 0.75 gal. or less per 1,000 cu.ft., while wet or casinghead gas is natural gas which is produced from oil wells and contains gasoline vapours, recoverable as liquid, to the extent of more than 0.75 gal. per 1,000 cubic feet. There are well known instances of gas coming from gas wells in which the gasoline content is more than 1 gal. per 1,000 cu.ft. and there are many instances of gas coming from oil wells wherein the gasoline content is less than 0.25 gal.¹ per 1,000 cubic feet.

Special types of natural gas containing the following substances are here arbitrarily classified: hydrogen sulphide and organic sulphur compounds; helium; nitrogen in excess of 10% by volume; carbon dioxide in excess of 10% by volume; vapours of carbon compounds, normally liquid, other than paraffin hydrocarbons. Natural gas which contains hydrogen sulphide, or organic sulphur compounds, is produced at: Glasgow, Ky.; Olney, Ill.; Findlay, O.; from some wells near Monroe, La.; Lower Oriskany Sand, Pa. (7,740 ft.); and Gulf coast and west Texas regions. Natural gas which contains helium has been found in Kansas, Oklahoma and Texas. Natural gas which contains nitrogen in excess of 10% by volume has been obtained in several counties in Kansas, and occurs in many wells in west Texas from the Panhandle on the north to Mitchell county on the south. The content of nitrogen is so high in some of the gas from the wells in west Texas that the gas is non-combustible.

Gasoline Recovery from Gas.—There are three processes of recovering gasoline from natural gas: The compression and cooling process; the oil absorption process; and the charcoal, or silica gel, adsorption process.

The *compression* process is practised under pressures varying from 90 to 300 lb. per square inch. Natural gas is used, whose gasoline content varies from 1 to 14 gal. per 1,000 cubic feet. The compressed gas is cooled generally by passing it through water-cooled pipes or intercoolers in which low temperatures are maintained by refrigeration.

The *absorption* process consists in absorbing the gasoline hydrocarbon vapours from the gas by means of a suitable oil. The gasoline is separated and recovered from the absorbent oil by a distillation process. The denuded oil is then cooled and re-used in the absorbing cycle. The absorption process is practised at pressures as low as 1 lb. and as high as 350 lb., with natural gas containing as little as $\frac{1}{10}$ and as high as 3 gal. per 1,000 cu.ft.

The *adsorption* process consists in adsorbing the gasoline hydrocarbon vapours from the gas by the means of solid adsorbents, such as charcoal, silica gel and iron gel. The gasoline is separated and recovered from the adsorbent by a distillation process. The denuded adsorbent is cooled by means of residue gas and when cooled is used cyclically in the adsorbing operation. Charcoal plants are now in operation at pressures from 5 lb. to 350 lb. and on gas of a gasoline content varying from $\frac{1}{10}$ to 1 gal. per 1,000 cubic feet. There are no technical limitations in the practice of both the oil adsorption and charcoal adsorption processes. The compression process is limited to the recovery of gasoline from natural gas of 1 gal. or greater content per 1,000 cubic feet.

The deepest natural gas producing well in the world is located on Chestnut Ridge at Ligonier, Pa., on the acreage of the Peoples Natural Gas Company. This well is 7,756 ft. deep and is drilled to the geological stratum known as the Stormville, which is below the Oriskany. The total length of pipe or "casing" is 3,433 m. and weighs 247 tons; temperature at 7,640 ft., 177° F or 65.21 ft. per degree above 60° F. The composition of the gas produced from this well is hydrogen sulphide—0.8%; car-

bon dioxide—0.1%; methane—98.8%; ethane—0.3%. The gas contains no vapours of the gasoline hydrocarbons. (J. B. G.)

NATURALIZATION: see NATIONALITY AND NATURALIZATION.

NATURALISM, in philosophy, is the view which maintains that all explanation should keep within the realm of what is natural, and avoid all recourse to the supernatural. Thinkers may be agreed about this even if they differ on many other points. Thus, for example, materialism, pantheism, positivism are all naturalistic; but it is absurd to equate them for that reason.

NATURAL LAW, in science, means the formulation of some uniform characters or connection of things or events; but it is frequently used for the uniformity itself as it exists in natural phenomena. Any such uniformity may be called a natural law (e.g., all the laws formulated in Physics and Chemistry). On the other hand the term "Law of Nature" is sometimes restricted to irreducible or ultimate laws (like the Law of Gravitation), as distinguished from derivative laws (like Kepler's three laws of planetary motion). See LAW (in science, etc.); SCIENTIFIC METHOD; J. S. Mill, *System of Logic* (1875, etc.).

NATURAL RESOURCES, CONSERVATION OF. This term came into common use in the United States early in the present century and had public attention focused upon it by a conference of governors of the States, called by President Roosevelt on May 13-15, 1908. Before adjourning, the conference adopted a declaration of principles of conservation. Several States have since formed conservation commissions, and many countries (1929) have equivalent bodies. The general principles of wise and thrifty use of natural resources have come to be observed throughout the world.

Productive use of agricultural land, continuous production of forests, skilful development of waters coupled with the protection of their forests, economy in the use of mineral reserves, the building up of fisheries, the increase of the protection of wild life and the proper handling and safeguarding of recreation resources are instances of conservation. Use of natural resources without waste, economic development to secure from them the maximum service, continuous production of renewable resources and permanence of industries and of community life, lie as the basis of the conservation principle. In the article entitled PHYSICAL RESOURCES OF THE WORLD, a description is given of the known reserves through which the principle of conservation may become operative.

NATURE. In the history of philosophy the term "nature" has been used in various inconsistent senses, corresponding more or less to the different attitudes which thinkers adopted towards the material part of the world in relation to the rest. The early Greek thinkers known as the hylozoists were not conscious of any fundamental difference between mere matter, on the one hand, and life and consciousness on the other. For them, accordingly, "nature" (*φύσις*) included everything that is, or that ever came into being (Latin *natura* from *nasci*, to be born). Later on the Sophists contrasted the "natural" with the "conventional," or that which anything is originally and what it is as the result of human intervention. In this way they and others described as conventional not only law and custom, but even colours and other secondary qualities in contrast with matter and motion. Thus the "natural" came to be contrasted with the "human" and, of course, the superhuman. Then owing partly to the influence of Plato, and partly to the influence of Christianity, it became customary to set body and mind (to say nothing of Platonic "Ideas," the "Good," and God, etc.) sharply against one another, and to identify "nature," or "the world and the flesh," with the material part of the universe only. This is one of the reasons for the rather common tendency to identify "naturalism" with materialism. With the Renaissance there came a more friendly attitude towards the material world, and the older Greek conception of "nature" was revived. And so in due course we find in Bruno and Spinoza, among others, the term "nature" used in the all-comprehensive sense of the entire universe—a sense which, of course, excluded the possibility of anything "supernatural." Hence the other meaning of the term "naturalism," merely as the antithesis to "supernatural-

¹American gallons.

ism" in science and philosophy. For the conception of nature in recent science see A. N. Whitehead, *The Concept of Nature* (1920).

NATURE RESERVES. The name nature reserve has been applied rather vaguely to any area withdrawn from ordinary human interference so that the flora and fauna, as well as the physical changes of ground, may follow their natural course. Included among motives for reservation is the desire to preserve the remnants of unique vegetations, the breeding-grounds of particular species of birds, sanctuaries for birds and big game, or landscapes.

The movement in favour of nature reserves, which had its historic origin in 1832 when the Congress of the United States definitely set aside Hot Springs reservation (Arkansas), has grown in strength in recent times. An important landmark was the establishment of the Yellowstone National Park in 1872 (area, 3,348 sq. miles), followed in 1890 by Sequoia reservation, by which several groves of these ancient and world-famous trees (*Sequoia gigantea*) were definitely withdrawn from the danger of destruction. Whilst the United States, the undoubted pioneers in this field, held, in 1928, 20 National parks with a total area of 11,846 sq. miles, and 60 minor areas termed National monuments, the establishment of reserves has become world wide.

As yet no standardized classification of such areas can be given. Thus in Great Britain the authorities range from single individuals or groups, local societies and town and county councils (or the like), to the National Trust, a society founded in 1895 and incorporated in 1907 "for the preservation of Places of Historic Interest or Natural Beauty." By 1928 this body held about 150 separate stations of which, whilst many were of definite historic interest, others of scenic beauty (mountains, downs, coast lines), a definite minority, including Wicken fen (Cambs.), Blakeney point and Scolt head (Norfolk), Hawksmoor (Staffs.) and many other areas are nature reserves and are administered and are being used for study and research. In an old and settled country like England large areas of virgin territory, comparable to the Yellowstone park, are out of the question, but smaller parcels are continually being acquired.

In recent years attention has been paid to the protection of birds' breeding grounds, especially sea-birds, as in the case of the Farne islands, Blakeney point and Scolt head. Thus Blakeney point, presented to the National Trust in 1912 for its representative shingle, dune and salt-marsh vegetations, now possesses perhaps the finest ternery in the British Isles, where five species regularly breed, including large numbers of Sandwich terns.

In other parts of the British empire great efforts are in progress for the provision of worthy reservations. This applies to Canada, South Africa, with its Paul Kruger reserve (a sanctuary for big game), Australia, New Zealand, with its innumerable scenic reserves and the recently established Otari "open-air native plant museum"—a remnant of virgin forest near Wellington where a living collection of plants indigenous to New Zealand is being established.

Other countries show results equally inspiring, and the Scandinavian group, Poland, Germany (where Conwentz was a notable pioneer), Czechoslovakia and Japan, vie with one another; Holland is outstanding for its bird sanctuaries.

See also PROTECTION OF ANIMALS, BIRDS, PROTECTION OF, BIRD SANCTUARIES, GAME RESERVES. (F. W. O.)

NAUGATUCK, a borough of New Haven county, Connecticut, U.S.A., occupying 16.8 sq.m. on the Naugatuck river, 15 m. N. by W. of New Haven. It is served by the New York, New Haven and Hartford railroad, and there is an aviation field 6 m. from the business district. Pop. (1920) 15,051 (32% foreign-born white); 1928 local estimate 17,000. The principal public buildings, including a fine high school, are grouped around the central green. A mile to the north is the 18th century Porter tavern, and 2 m. south the Collins tavern (1810), a noted stopping-place on the stage-coach route between New Haven and Litchfield. The manufacture of rubber goods (including 25,000 pairs of shoes and boots daily) is the leading industry, and one of the largest rubber-regenerating plants in the world is situated here. Other important products are safety-pins (1,000,000 daily), candies, malleable

iron castings, copper floats and airplanes. The aggregate factor output was valued at \$15,548,056 in 1925. Naugatuck was the home of Charles Goodyear (q.v.) who in 1839 invented the process of vulcanizing rubber. The name is an Algonkin word meaning "one tree."

NAUHEIM or **BAD-NAUHEIM**, a watering-place in Germany, in the republic of Hesse, situated on the north-east slope of the Taunus mountains, 24 m. by rail N. of Frankfurt on-Main on the main line of railway to Cassel. Pop. (1925) 9,193. Nauheim, which was bestowed by Napoleon upon Marshal Davout, became a town in 1854. From 1815 to 1866 it belonged to the electorate of Hesse-Cassel, but in 1866 it was ceded to the grand-duchy of Hesse-Darmstadt. Its thermal waters (84° to 95° F), although known for centuries, were, prior to 1835, only employed for the extraction of salt. The waters, which are saline strongly impregnated with carbonic acid, and to a less extent with iron, are principally used for bathing, and are specific in cases of gout and rheumatism, but especially for heart affections. Three smaller springs, situated outside the Kurpark, supply water for drinking. In 1899-1900 a new spring (saline) was tapped at a depth of 682 ft. Another attraction of the place is the Johannisberg, a hill 773 ft. high, overlooking the town.

NAUKRATIS, an ancient Greek settlement in Egypt. The site was discovered by Professor W. M. Flinders Petrie in 1883 on the eastern bank of a canal, about 10 m. W. of the present Rosetta branch of the Nile. In ancient times it was approached by the Canopic mouth, which was farther to the west. The identification of the site is placed beyond doubt by the discovery of inscriptions, with the name of the town, and of great masses of early Greek pottery. The site was excavated in 1884-86 by the Egypt Exploration Fund, and a supplementary excavation was made by the British School at Athens in 1899. A list of the temples of Naukratis is given by Herodotus (ii. 178); they were the Hellenion, common to all the colonizing cities, and those dedicated by the Aeginetans to Zeus, by the Samians to Hera, and by the Milesians to Apollo. A temple of Aphrodite is also mentioned by Athenaeus. Traces of all these temples, except that of Zeus, or at least dedications coming from them, have been found in the excavations, and another has been added to them, the temple of the Dioscuri. In addition to these temples, there was also found a great fortified enclosure, about 860 ft. by 750, in the south-eastern part of the town; within it was a square tower or fort. A portico of entrance and an avenue of rows of sphinxes was added in Ptolemaic times, as is shown by the foundation deposits found at the corners of the portico; these consisted of models of the tools and materials used in the buildings, model of instruments for sacrifice or ceremonies, and cartouches of King Ptolemy Philadelphus. Dr. Hogarth subsequently found traces of another great walled enclosure to the north-east of the town, together with pottery dedicated *τοῖς τῶν Ἑλλήνων θεοῖς* and he claims with reason that this enclosure is more likely than the other to be the Hellenion.

Apart from the historic interest of the site, as the only Greek colony in Egypt in early times, the chief importance of the excavations lies in the rich finds of early pottery and in the inscriptions upon them, which throw light on the early history of the alphabet. There are clear traces of a settlement going back to the 7th century, including a scarab factory, and yielding fragments of early Greek pottery. It seems a fair inference that the makers of these were Greeks, and that they probably represent the early Milesian colony, settled here in the time of Psammetichus I.

NAULETTE, a large cavern on the left bank of the Lesse which joins the Meuse above Dinant, Belgium. Here in 1861 Edouard Dupont discovered an imperfect human lower jaw, now in the Brussels Natural History Museum. It is of a very ape-like type in its extreme projection and that of the teeth socket (teeth themselves lost), with canines very strong and large molar increasing in size backward. It was found associated with the remains of mammoth, rhinoceros and reindeer. The Naulette man is now assigned to the Mousterian Epoch.

See G. de Mortillet, *Le Préhistorique* (1900); J. Dechelette, *Archéologie*, vol. i. p. 281 (1912).

NAUMACHIA, the Greek word denoting a naval battle (*ναῦς*, ship, and *μάχη*, battle), used by the Romans as a term for a mimic sea-fight. These entertainments took place in the amphitheatre, which was flooded with water, or in specially constructed basins (also called *naumachiae*). The first on record, representing an engagement between a Tyrian and an Egyptian fleet, was given by Julius Caesar (46 B.C.) on a lake which he constructed in the Campus Martius. In 2 B.C. Augustus, at the dedication of the temple of Mars Ultor, exhibited a naumachia between Athenians and Persians, in a basin probably in the *horti Caesaris*, where subsequently Titus gave a representation of a sea-fight between Corinth and Corcyra. In that given by Claudius (A.D. 52) on the *lacus Fucinus*, 19,000 men dressed as Rhodians and Sicilians manoeuvred and fought. The crews consisted of gladiators, condemned criminals, and in later times, volunteers.

See GAMES: Classical; Rome: Ancient City; PANATHENAEA.

NAUMBURG, a town in the province of Prussian Saxony, the seat of the provincial law courts and court of appeal for the province and the neighbouring districts. It is situated on the Saale, near its junction with the Unstrut, 29 m. S.W. from Halle, on the railway to Weimar and Erfurt. Pop. (1925) 29,339. In the 10th century Naumburg was a stronghold of the margraves of Meissen, who in 1029 transferred to it the bishopric of Zeitz. In 1564 the last bishop died, and the bishopric fell to the elector of Saxony. In 1631 the town was taken by Tilly, and in 1632 by Gustavus Adolphus. It became Prussian in 1814. The cathedral, a building in the Romanesque Transition style (1207-42), has a Gothic choir at each end, and contains some mediaeval sculptures. It is remarkable for its large crypt and its towers.

NAUNDORFF (or NAUNDORFF), **KARL WILHELM** (d. 1845), French pretender, claimed to be the dauphin, Louis Charles, son of Louis XVI. and Marie Antoinette, who was announced as having died in the Temple in 1795.

Naundorff, who had arrived from nowhere in Berlin in 1810, with papers giving the name Karl Wilhelm Naundorff, in order to escape the persecutions of which he declared himself the object, settled at Spandau in 1812 as a clockmaker, and married in 1818 Johanna Einert. In 1822 he removed to Brandenburg, and in 1828 to Crossen, near Frankfurt. He was imprisoned from 1825 to 1828 for coining, though apparently on insufficient evidence, and in 1833 came to push his claims in Paris, where he was recognized as the dauphin by many persons formerly connected with the court of Louis XVI. Expelled from France in 1836, the day after bringing a suit against the duchess of Angoulême for the restitution of the dauphin's private property, he lived in exile until his death at Delft on Aug. 10, 1845, and his tomb was inscribed "Louis XVII., roi de France et de Navarre (Charles Louis, duc de Normandie)."

BIBLIOGRAPHY.—For the case of Naundorff see his own narrative, *Abrégé de l'histoire des infortunes du Dauphin* (1836; Eng. trans., 1838); also Modeste Gruau de l'Barre, *Intrigues dévoilées ou Louis XVII. . .* (3 vols., Rotterdam, 1846-48); O. Friedrichs, *Correspondance intime et inédite de Louis XVII.* (Naundorff) 1834-38 (2 vols., 1904); *Plaidoirie de Jules Favre devant la cour d'appel de Paris pour les héritiers de feu Charles-Guillaume Naundorff* (1874); H. Provins, *Le Dernier roi légitime de France* (2 vols., the first of which consists of destructive criticism of Beauchêne and his followers, 1889); A. Lanne, "Louis XVII., et le secret de la Révolution," *Bulletin Mensuel* (1893, et seq.) of the Société des études sur la question Louis XVII., also *La Légitimité* (Bordeaux, Toulouse, 1883-98). See further, the article "Naundorff" in M. Tourneux, *Bibl. de la ville de Paris pendant la Révolution*, vol. iv. (1906).

NAUNTON, SIR ROBERT (1563-1635), English politician, was educated at Trinity college, Cambridge, of which he became a fellow in 1585. He entered parliament in 1606 for Helston, and sat in five successive parliaments. Through Buckingham's influence he became secretary of State in 1618; his strong Protestant opinions and enforcement of the laws against the Catholics brought complaints from the Spanish ambassador Gondomar and censure from the king. Naunton then resigned. He died at Letheringham, Suffolk, on March 27, 1635. He wrote *Fragmenta Regalia* (1641, 2nd ed. 1653; Arber reprint, 1870), a valuable account of Elizabeth's reign.

See *Memoirs of Sir Robert Naunton* (1814).

NAUPLIA, a town in the Peloponnesus, at the head of the Argolic Gulf, the seaport of the plain in which Argos and Mycenae are situated, with several tombs of the Mycenaean age. A hero Nauplius took part in the Argonautic expedition; another was king of Euboea. In classical times it was of no importance, and Pausanias, about A.D. 150, found it deserted. The mythic importance of the town revived in the middle ages, when it became chief city of the Morea. It was captured in 1211 by Godfrey Villehardouin with the help of Venetian ships; a French dynasty ruled in it for some time, and established feudalism. In 1388 the Venetians bought Argos and Nauplia. In the wars between Venice and the Turks it often changed masters: given to the Turks in 1540, it was recaptured by Venice in 1686, and the Palamidhi hill overhanging the town was fortified. In 1715 it was taken by the Turks; in 1770 the Russians occupied it for a short time. The Greeks captured it during the War of Independence on the 12th of December 1822, and it was the seat of the Greek administration till 1833, when Athens became the capital of the country. It is the chief town of the department of Argolis. Pop. (1923) 7,300.

NAURU: see PACIFIC ISLANDS.

NAUSEA, sea-sickness, or generally any disposition to vomit; also used figuratively to denote feelings of strong aversion or dislike.

NAUSICAA, in Greek legend, daughter of Alcinous, king of the Phaeacians in the island of Scheria (*Odyssey*, vi. 15-315, viii. 457). When Odysseus (*q.v.*) swam ashore to Scheria, he was found by Nausicaa, who supplied him with clothes and took him to her father's palace, where he was hospitably entertained.

NAUTCH, an Indian ballet-dance (Hindustani *nach*). The nautch is performed by nautch-girls, who scarcely move their feet, and the dance consists of swaying and posturing with the arms.

NAUTILUS, the name given by the ancient Greeks to a cephalopod mollusc, *Argonauta argo* (the paper nautilus). Linné, however, applied it as a scientific designation to another cephalopod, the pearly nautilus of eastern seas, and named the "nautilus" of the Greeks, *Argonauta*. The structure and zoological position of the pearly nautilus are discussed in the article CEPHALOPODA. It is represented at the present time by four species, which are restricted to the area between the Fiji and the Philippine islands. It usually lives near the sea bottom at considerable depths, though at night it comes into shallow water where it is caught for food by the natives.

The paper nautilus (*Argonauta*) is found in practically all sub-tropical and tropical seas. Although it has been taken from depths over 500 fathoms it is characteristically found at the surface. It is placed along with a few other genera in a separate family of the Octopoda or eight-armed cephalopods. The genus is characterized by several very peculiar features. In the first place the male *Argonauta* is very much smaller than the female, the latter in certain cases being as much as 15 times the size of the male. Like the rest of the Octopoda the male *Argonauta* lacks an external shell, but the two dorsal arms of the female secrete a calcareous shell which is unique in the mollusc phylum. Its origin from the arms is unlike that of the shell of other molluscs which is developed from the mantle. Moreover this shell is used as a receptacle for the eggs and in it they are incubated until the young are hatched out.

NAUVOO, a city of Hancock county, Illinois, U.S.A., on the Mississippi river at the head of the lower rapids and about 50 m. above Quincy. Pop. (1920) 972. On the opposite bank of the river is Montrose, Iowa, pop. (1920), 549, served by the Chicago, Burlington and Quincy railway. "Commerce City" was laid out here in 1834 by Connecticut speculators; but the first settlement of importance was made by the Mormons (*q.v.*) in 1839-40; they named it Nauvoo, in obedience to a "revelation" made to Joseph Smith, and secured a city charter in 1840. The Mormons said the name was of Hebrew origin and meant "beautiful place"; Hebrew "naveh" means "pleasant." In 1844 its population was

about 15,000, and a large Mormon temple had been built, but internal dissensions arose, "gentile" hostility was aroused, the charter of Nauvoo was revoked in 1845, two of the leaders, Joseph Smith and his brother Hyrum, were killed at Carthage, the county-seat, by a mob, and in 1846 the sect was driven from the State. Traces of Mormonism, however, still remain in the ruins of the temple and the names of several of the streets. Three years after the expulsion of the Mormons, Nauvoo was occupied by the remnant (some 250) of a colony of French communists, the Icarians, who had come out under the leadership of Etienne Cabet (q.v.). For a few years the colony prospered, and by 1855 its membership had doubled. Each family occupied its own home, but property was held in common, all ate at the common table, and the children were taught in the community school. A proposal to revise the constitution resulted in rending the colony into two irreconcilable factions, and in Oct. 1856 Cabet with the minority (172) withdrew to St. Louis, Mo. Soon after the schism of 1856 those who had rebelled against Cabet began to prepare a permanent home in Adams county, Iowa. There too in 1879 the community split into two factions, the Young Party and the Old Party. Most of the members of the Young Party removed to Sonoma county, Calif., and here early in 1884, formed the Icaria-Speranza Community. All branches of the society ceased to exist after 1895.

See Albert Shaw, *Icaria: A Chapter in the History of Communism* (1884); Jules Prudhommeaux, *Icaria et son fondateur Etienne Cabet* (1907).

NAVAHO, an Athabascan people in northern Arizona and New Mexico, situated between the various Pueblo Indians. They are first mentioned about 1630; they may have been met by the Spaniards before this without being distinguished from the Apache. They are probably an Apache division in origin, specialized through contact with the Pueblos. Their territory comprises the heart of the prehistoric Pueblo area about Chaco canyon and other affluents of the San Juan river; but they have never adopted the masonry houses, sedentary life, or, except to limited extent, agriculture of the Pueblos. For several centuries they raided these people and the Spanish-Mexican colonists, drove off their stock, and gradually acquired herds of horses, cattle, goats and especially sheep, from which their living is still largely derived. They are noted for their blankets and silver work. Their great ceremonies last nine days. The Navaho are matrilineal, their 50-60 clans bearing the names of localities but being exogamous. Their houses are of stick and earth covered on a foundation of logs; they make very little pottery and basketry. The original population was probably only a few thousand; it is thought to have reached 9,000 in 1869, and since 1900 has been variously reported from 20-28,000.

NAVAL AND MILITARY SCIENTIFIC SOCIETIES. The *Royal United Service Institution*, first known as the *Naval and Military Library and Museum* (1831), took the name of the *United Service Institution* in 1839, and was incorporated in 1860; its professional museum is housed in the banqueting hall at Whitehall; it publishes a *Journal* (1857, etc.). The *Institution of Naval Architects* (1860) publishes *Transactions* (4to, 1860, etc.). The *Royal Artillery Institution* (1838), which issues the *Royal Artillery Journal*, is at Woolwich, and the *Institution of Royal Engineers* (1875), which issues the *R. E. Journal*, at Chatham. The *Navy Records Soc.* (1893) publishes works connected with the history of the British Navy. CANADA: Toronto, *Military Inst.* INDIA: Simla, *United Service Institution*.

UNITED STATES: New York, *Military Service Inst.* (1878), *Journal* (1879, etc.); Soc. of Naval Architects and Marine Eng., Proc. Annapolis, U.S. Naval Institute (1873), Proc. FRANCE: Paris, *Réunion des Officiers*, now *Cercle Militaire*, Bull. (1871, etc.). GERMANY and AUSTRIA-HUNGARY: Munich, *Militär. Ges.* (1868), *Jahrbuch*. (1871, etc.). Vienna, *K. k. NORWAY: Christiania, *Militære Samfund*, *Nordisk Militär Tidsskrift* (1848, etc.). DENMARK: Copenhagen, *Krigsvitenskabelige Selskab*, *Milit. Tidsskrift* (1872, etc.).

NAVAL ARTICLES. The subject of navies generally is dealt with in the article NAVY AND NAVIES.

The navies of the various nations are dealt with under the name of each nation, but separate articles have been allotted to the various types of warships, e.g., AIRCRAFT CARRIER, BATTLESHIP, CRUISER, DESTROYER, FLEET AUXILIARY VESSELS, SUBMARINE.

Historical aspects are dealt with under NAVY: GREAT BRITAIN, UNITED STATES, WORLD WAR: NAVAL, while important operations or engagements, such as ARMADA, BELGIAN COAST (including Zeebrugge), COPENHAGEN, CORONEL, DARDANELLES, DOGGER BANK, DUTCH WARS, FALKLAND ISLANDS, FIRST OF JUNE, FRENCH REVOLUTIONARY WARS, JUTLAND, NAPOLEONIC CAMPAIGN, NAVARINO, NILE, QUIBERON, SAINTS, SEVEN YEARS' WAR, ST. VINCENT, Toulon, TRAFALGAR, are found under their appropriate headings.

Biographies of distinguished naval commanders will be found under their names.

For a more general study of naval warfare, see articles on BLOCKADE, COAST DEFENCE, CONVOY, FUELLING STATIONS, NAVAL BASES, NAVAL STRATEGY AND TACTICS, SEA POWER.

Technical articles in addition to those dealing with each type of ship include ANCHOR, ARMOUR PLATES, BUOY, CAMOUFLAGE, CABLE, CAPSTAN, CHRONOMETER, DEPTH CHARGE, FIRESHIP, FLEET, FRIGATE, GALLEY, GUNNERY, LOG, MINES, MINELAYING AND MINESWEEPING, ORDNANCE, PARAVANE, PILOTAGE, PILOTAGE LAWS, RANGE FINDERS, RULE OF THE ROAD AT SEA, SEAMANSHIP, SHIP, SHIPBUILDING, SHIPS' FIGUREHEADS, TORPEDOES, WASHINGTON TREATY.

Administration and personnel will be found dealt with under ADMIRAL, ADMIRALTY, CAPTAIN, COURT MARTIAL, CREW, MARINES, MEDICAL SERVICE, MIDSHIPMAN, NAVY DEPARTMENT, PRESS GANG, STAFF, UNIFORM.

NAVAL STORES, a trade name for the products derived from the oleoresin (gum or pitch) of the pine tree. As originally used the term included all raw materials used in building and maintaining sailing vessels as for instance, tar, pitch, rosin, flax, cordage, masts and timber. The possibility of obtaining a source of supply for these materials independent of Russia and the Dutch traders had considerable influence upon the British in establishing the colonies in Virginia. Flax, cordage and lumber are no longer classed as naval stores. The term embraces turpentine, rosin, pine oil, pine tar, pine tar oil, pitch and rosin oil. Charcoal from the destructive distillation of "lightwood" and pine needle oil are sometimes included but are not generally considered to be true naval stores products. The former is made from the wood and not from the oleoresin of the tree and the latter is an essential oil usually classed under drugs and chemicals.

From 65% to 70% of the world's production of naval stores comes from the United States, half the rest from France, with Spain, Greece, Portugal, Mexico and India following in order and small amounts coming from Austria, Russia, Finland, Scandinavia, Philippines and Japan. The total value of the naval stores crop to the producers of the United States is about \$50,000,000. It is all produced in the southern pine belt and includes North and South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana and a small part of Texas. American naval stores come from the long-leaved pine (*Pinus palustris* or *Pinus australis*) and the slash or Cuban pine (*Pinus Caribaea*). The French source of naval stores is the maritime pine (*Pinus Pinaster*) in the Landes.

There are three distinct methods of manufacture, and the products therefrom vary widely in their characteristics. By far the greatest amount of naval stores is produced by the gum method. The trees are "chipped" and the oleoresin which exudes from the wood in order to heal the wound is caught in cups, collected each week and transported to a still. The volatile material is distilled off with steam and condensed as gum turpentine. The residue is gum rosin and is run out of the bottom of the still, strained through cotton batting into troughs and dipped into barrels. The rosin is graded according to colour and freedom from dirt—the lightest grades being X, WW, WG, N, M; the medium grades being K, I, H, G and F; and the dark grades B and D.

DD turpentine, DD pine oil, pine tar, pine tar oil and charcoal

are produced by the destructive distillation of the dead wood and stumps left on the ground after the lumbering industry has taken off the timber. Long-leaved pine wood contains only 5% resinous material, but the dead wood and stumps may contain as high as 40% and wood can be obtained in commercial quantities with more than 20% resinous material. Destructive distillation was originally carried out in the woods by covering a pile of dead wood with sod, clay, etc., and burning the pile with an insufficient amount of air to form complete combustion. The process is now carried out in well designed retorts where all volatile materials can be recovered.

The third method of manufacture is the so-called steam-distillation, solvent-extraction process, wherein the dead wood and stumps from cut-over land are ground up, loaded into steel retorts, steamed with live steam to obtain turpentine and pine oil and then extracted with boiling gasoline to obtain rosin. The production of steam distilled wood turpentine, and wood rosin is equal to 20% of America's output of gum turpentine and gum rosin.

Turpentine and rosin in the United States are consumed in the following industries: paint and varnish; soap; rosin oil, greases and printing inks; shoe polish and leather dressing; motor cars, buggies, wagons; sealing wax and insulation; oils and greases; linoleum, oil cloth and roofing; foundries and foundry supplies; shipyards; pharmaceuticals and chemicals; matches and wooden ware; and various other fields.

See Gamble's *Naval Stores Year Book* (Savannah, Ga.).

(V. R. C.)

NAVAL STRATEGY AND TACTICS. Naval strategy in its broad sense does not differ in principle from any other war strategy. It may be defined as the disposition of forces *vis-à-vis* those of the enemy outside the actual battle arena. The term must not be confused with tactics, which relate to the disposition and employment of forces in battle. Whereas certain well-defined principles governing sound strategy can be culled from history and adapted to present-day conditions, tactics must be studied chiefly in relation to weapons and mobility, factors which have changed repeatedly in the past and which must continue to change with the march of science and the development of material.

It is a defect in not a few works on naval warfare that the writers do not differentiate clearly between strategy and tactics in appraising the value of historical examples; but history, modern as well as ancient, establishes certain immutable strategical principles governing the use and disposition of forces in war. As applied to naval warfare these may be summarised as follows:—

(1) Naval efforts, like military operations, must always be subordinate to government policy; but although political aims may tend to influence war plans, they should never be allowed by ministers and their professional advisers to dictate a course of action which is at variance with sound strategy. (2) The primary mission of a navy in war is to deny the use of the sea to the enemy, while preserving it for friendly interests. (3) Concentration of effort must always be aimed at, because with it goes the conservation of energy and economy of force.

History provides a number of examples where political aims have conflicted with the correct military objective in war, and where the subordination of the latter to the former has imperilled the issue. This condition of affairs has almost invariably arisen from a lack of community in thought and in counsel between political leaders and the heads of the fighting Services. On occasion the latter have been deliberately excluded from councils where the most momentous decisions regarding the conduct of war have been taken. On others, although present, they have, through a false sense of diffidence or through being personally inarticulate, failed to give the Government the benefit of their professional knowledge and experience. This defect in the machine of State has been remedied to a great extent of late by the British Government, who have now charged the three professional heads of the navy, army and air force with the duty of presenting collective advice on all defence matters to the committee of Imperial Defence, of which these three high officers are permanent members, while the Prime Minister or his deputy is chairman. In other respects the composition of this committee varies

with the problem under review, so that it always possesses a truly representative character. On the outbreak of hostilities it would doubtless be transformed into a War Cabinet which would enunciate the war policy governing the strategic disposition and employment of the fighting forces. Fundamentally that policy must be directed towards the attainment of the one clear purpose for which a nation takes up arms, namely to impose its will so effectively on the enemy that he will sue for peace on that nation's own terms.

In the past it has frequently occurred that effort has been dispersed and wasted by engaging in attractive, but subsidiary, projects whereby the main object was lost sight of and the war unduly protracted. As an example may be quoted the misuse of a large proportion of the British fleet during the years 1793–5 in operations directed to acquire French and Dutch possessions in the West Indies. The assumption was that this course would add to British resources and reduce those of the enemy, but in effect it jeopardised sea security to an extent which might have proved disastrous. By dispersal of strength, the British fleet in the Mediterranean was at one time five sail of the line below the number of the French fleet at Toulon. As the First Sea Lord of that day, Sir Charles Middleton, wrote: "It is this system of unlimited conquest that cripples us everywhere and diverts the fleet from its natural uses. . . . But for this system, half the number of ships now employed in the West Indies and in army convoys would have been sufficient and the French be prevented from sending a single ship to sea." Here was the case of a political aim, the capture of possessions, being allowed to outweigh the sound military object of bringing to action or neutralising the enemy's principle naval forces. With the enemy main fleet defeated or closely blockaded, England would have secured the unchallenged use of the seas, while they would have been denied to her enemy. Even if this did not of itself end the war, it would have greatly facilitated any subsequent project for territorial conquest.

With regard to the primary mission of a navy in war, it was for long maintained that the chief object of the fleet should be to engage that of the enemy. To such an extent did this doctrine obsess certain minds that as lately as the year 1914 it was asserted by a distinguished British naval authority that the Admiralty ought not to be responsible for the passage of the British Expeditionary Force to France until the German High Seas Fleet had been defeated.

There can be no doubt that, as a means of fulfilling its true mission, the destruction of the enemy's main fleet is of very great importance, because it is the most drastic and probably the most effective action which can be taken to deprive him of the use of the sea. But under modern conditions it is extremely improbable that an adversary would risk an obviously inferior fleet in an encounter which is likely to end in disaster. Moreover, nowadays, an inferior fleet can safeguard itself against being forced into an unequal contest by outer defences, such as mines and submarines, which enable it to lie in secure retreat, where at least it exerts the influence of a "fleet in being"; a potential danger and therefore a drain on the opponent's warlike resources. The old days when it was possible to invade an enemy harbour and destroy his fleet at anchor, as Nelson did at Aboukir Bay and Codrington at the battle of Navarino, are no more, although in the not too distant future the development of air power may recreate the possibilities of attacking an enemy fleet, in its base. To argue that the principal duty of a navy is to defeat the main fleet of the enemy is, however, to confuse the object with the means of its attainment. It is nevertheless a first essential in the strategical disposition of naval forces that the main fleet should be so based *vis-à-vis* the enemy's main fleet that any and every opportunity of bringing the latter to action can be seized. The importance of this is self-evident when it is realised that all other naval dispositions must depend for their security and efficiency on the main fleet being able to counter effectively any attempt by the enemy to take the offensive with superior forces.

No more striking example of this statement can be found than that given by British naval strategy in the World War. At the

mere threat of hostilities the Grand Fleet, as it was afterwards called, went to its war base at Scapa Flow. Later the Firth of Forth was developed sufficiently to allow it to move south to this more convenient anchorage. But throughout the War this predominant force, far up in the North Sea, contained the German High Sea Fleet so effectively that the latter was unable to prevent the complete eviction of German cruisers from the seas and the passage of armies and war materials to do battle against the German army and its allies in whatever part of the world their enemies desired. Such was the balance and interdependence of naval and military strategy throughout the war that the security and maintenance of the British and allied armies in every theatre of war was directly dependent on the British main fleet in the North of Scotland. (See also **BATTLESHIP AND BELGIAN COAST OPERATIONS.**)

Although British naval strategy in the World War proved to be sound enough in the main, some serious blunders were made, notably in the case of the Dardanelles campaign. Owing to the lack of a properly constituted naval staff at the Admiralty at that time, there was no clear appreciation of the influence and limitations of warships when used in conjunction with military forces on a sea coast or of the support they could give to an opposed landing. These limitations hinge largely on two tactical principles which may be stated in general terms to be: (1) Ships' gun-fire cannot dominate territory threatened by hostile land forces, save for a very limited period. (2) Ships' gun-fire cannot be relied upon to destroy enemy guns mounted on shore; or in other words ships' gun-fire may be able to keep down the fire of land batteries for a limited period, but it will probably break out again as soon as the ships withdraw or cease firing owing to expenditure of their ammunition.

The strategy which governed the employment of naval forces at the Dardanelles was not co-ordinated with military effort as it would have been had there been proper co-operation between a fully developed naval staff at the Admiralty and the General Staff at the War Office. The ultimate object necessitated occupying and holding both banks of this narrow waterway; the initial conception of ships blasting their way through it in the face of land defences and mined channels and eventually threatening Constantinople at the point of their guns was proved to have been fundamentally unsound. The employment of ships to bombard the shore defences before military forces were available in sufficient strength to ensure a successful landing and advance on both sides to the straits was a strategical error of judgment which prejudiced the campaign at the very outset. The best that can be said of the Dardanelles expedition as it was actually carried out is that it acted as a diversion on a large scale, holding up forces and distracting the attention of the enemy to an extent which assisted operations in other theatres of war. But there can be no question that, as a diversion, the huge expenditure of life and war material was not justified, while as a major operation it failed, owing to lack of proper strategical co-ordination. As such it must remain an historical example of the dire results of attacking prematurely with insufficient force, of failure to appreciate the interdependence of sea and land warfare in coastal operations and, lastly, of the vital necessity for clearly defining the object of a campaign and then for proper staff work to formulate the strategy to be employed before forces are put into motion.

DEVELOPMENT OF NAVAL TACTICS

It is quite conceivable that the most elementary tactics were those employed by the earliest antagonists afloat in their endeavours to board each other's craft and obtain victory by a hand to hand conflict. This primitive form of sea warfare held a recognised place in the tactical handling of fleets even up to the Trafalgar Era. Moreover we see instances of its unpremeditated revival even in the World War, notably in the hand to hand encounters which ensued when the flotilla leader "Broke" under Commander E. R. G. R. Evans charged into a German destroyer flotilla in the Straits of Dover on the night of April 20, 1917. "Boarding," as it came to be called, was an operation calling for considerable skill, whether in the ancient days of war canoes and

rowing galleys, or in later years when great sailing ships of the line grappled with each other yard-arm to yard-arm.

Contemporary with these boarding tactics was another early form of attack, namely that of using the ship itself as a ram. The ancient triremes, although they used sails for making a passage from place to place, found this method of propulsion was not sufficiently handy for fighting and ramming, and, before going into battle, oars were reverted to. We find similar methods adopted by Phormio, the Athenian Admiral of the 5th century B.C., by the Norse King Olaf Trygvesson of the 10th century A.D. and by the chiefs of the Christian and Turkish fleets at the Battle of Lepanto in A.D. 1571. In fact, for centuries naval tactics seem to have been moulded into a more or less common form. The vessels usually aimed at attacking in line abreast (see **FLEET**) the object being that action should be joined by all units simultaneously and that they should ram and subsequently board the enemy in a united effort. It was necessary to attack head on for boarding no less than for ramming, because the oars projected so far outside the opposing craft that they could not otherwise be brought close enough for the crew to jump the intervening space. It may be noted that this same difficulty prevailed in the case of sailing ships in later times, as they were built with "tumble home" sides, that is to say, with sides sloping inwards from the water line.

Success either in ramming or boarding depended, of course, on the skill with which each vessel was handled. The highly trained Athenian crews of the early Peloponnesian wars relied mainly on the ram. They usually endeavoured to sheer off the oars from one side of an opponent, and when he was at their mercy, turn and ram him in the stern. But ramming, whether by the rowing galley or the steel-shod battleship of much more recent times, has always proved an uncertain form of attack, for a very slight error of judgment may convert the rammer into the rammeé, while the impact may so seriously damage the bows of the ship ramming that she is left in considerable straits herself, even though she may have seriously damaged her adversary. Nevertheless we see the idea of ramming influencing warship design up to as late a period as 1911, when the last British battle-ships, the "Lord Nelson" and "Agamemnon," were built with ram bows.

Tactics on a more elaborate scale have developed with the increasing range of weapons. Such primitive armaments as bolts fired from heavy cross bows fixed on the bulwarks, bows and arrows, weights dropped from a yard or pole rigged over the side, and various incendiary projectiles, like burning tow attached to arrows or "Greek fire" blown through tubes, all necessitated close action. Even the introduction of guns did not at first produce much in the way of tactical manoeuvring, save with the object of getting the weather gauge, so long as their limitations necessitated fighting at almost point blank range. But tactical manoeuvring as we understand it to-day may however, be said to have been employed by the British fleet in its encounter with the Spanish Armada. In this historic conflict the Spanish ships suffered from first to last by being out-manoeuvred and out-ranged by their opponents. They towered out of the water like great high fortresses; but they depended for victory largely on the lines of infantrymen armed with pikes and muskets, which stood in serried ranks, awaiting the opportunity to board. But this the elusive English failed to give them. At the outset Drake, with his ships in single line ahead, sailed round the great fleet of Medina Sidonia, and while seeming at first to refuse battle, he obtained the exact position that he desired. Then each English ship in turn, using her longer ranging guns, opened an overwhelming and unanswerable fire on her adversary, mowing down the defenceless lines of infantry. Having discharged her broadside, each, in turn, swung round to take station astern, while her guns were reloaded. The result was to throw the Spanish fleet into a state of confusion and demoralisation, from which it never recovered and from which it suffered more and more during its unhappy passage up-channel and final dispersion when what ships remained fled into the open waters of the North sea.

In the first half of the 18th century the tactics of the British

Navy were severely restricted by flag officers in command of fleets being commanded by the official Fighting Instructions to adhere strictly to the ordered line of battle. Moreover they were not permitted to attack an enemy until that line had been correctly formed and until they were in a position for each ship to bear down like one of a row of infantry soldiers charging in line on their opposite numbers of the enemy's fleet. To such an extent had this become a fetish that Admiral Mathews, after his encounter with the Franco-Spanish fleet in 1744, was relieved of his command and tried by Court Martial, one of the two counts being that he engaged without having ordered and dressed his line.

But already there were to be found flag officers who refused to be tied by these academical restrictions. Chief amongst these was Admiral Vernon, who initiated and put into effect a number of reforms which broke away from the rigidity enforced by the official restrictions. Nelson was nothing if not enterprising in his tactics, and he seldom failed to seize the golden opportunity because it called for unconventional action. Trafalgar, the culmination of his great career and pinnacle of his fame, was fought in accordance with his intentions. The British fleet bore down in two lines on the approaching Franco-Spanish fleets, which were in a crescent formation. As an old naval authority puts it: "This novel mode of coming into action kept the enemy completely in suspense. It threatened every part of their line. If our two columns had turned the same way, they would have been able to do infinite damage in that quarter before the other wing of the enemy could come up to succour their overpowered fleets: if the two columns should cut through the centre, they must destroy it and effectively separate the two wings so as to leave them ignorant of each other's fate. Such was the fact: the enemy, though superior in numbers, lost no less than nineteen sail of the line."

But the tactics of the sailing navies must not be taken as suitable for guidance in naval tactics of the present day. Many new influences have arisen in sea warfare which have not merely extended the range at which battles must be fought, but have altered their whole character and conduct. Chief amongst these influences has been the introduction of steam, whereby a fleet can now disregard the direction of the wind so far as the actual propulsion of the ships themselves is concerned.

Next in order of importance is the introduction of underwater weapons, notably the self-propelled torpedo (*q.v.*). The increased power of the gun and the danger of torpedo attack have combined to rule out ramming and boarding as deliberate methods of attack. But the great tactical principle of seeking to concentrate the maximum available force on some part of the enemy's fleet in such a way that the rest of it cannot retaliate, or assist their hard-pressed companions, remains today just as much as in the past. But such an ideal tactical advantage can, generally speaking, only be secured by a fleet with greatly superior speed. Nevertheless it was achieved by masterly manoeuvring aided by conditions of low visibility when Admiral Jellicoe deployed the Grand Fleet across the head of the German High Sea Fleet in the opening stage of the main action at Jutland (*q.v.*). Even so, a skilful enemy may be able to extricate himself from what would otherwise be a disastrous position, and this the German Admiral, Scheer, succeeded in doing on two occasions during that battle. True, his method was merely to execute a precipitate right-about-turn, and the result clearly showed that although, diagrammatically, he was, at one moment, somewhat in the position of Nelson at Trafalgar, in that his fleet was heading for the centre of his opponents' battle line, yet both his subsequent manoeuvres and the results of the tactical situation, were as difficult as it is possible to conceive. Nelson deliberately designed such an approach; he charged on, and thereby achieved a great victory; Scheer accidentally found himself in a position where he was threatened with annihilation by the concentrated fire of the British battle fleet. He withdrew just in time, but sorely damaged, under cover of a heavy smoke screen and torpedo attack by his destroyer flotillas.

The tactical requirements of a modern fleet necessitate vari-

ous types of warships. The battleship remains as the predominant surface fighting unit. The battle cruiser claims certain tactical qualities, due to her greatly superior speed and power armament. But the limitation of capital ship tonnage by the Washington Treaty (*q.v.*) will probably see this type merged into that of the battleship. It is very questionable whether the lightly armoured British type of battle cruiser justified its existence as a fleet unit, however useful they may have proved in the World War when on detached service. The fleet type cruiser or light cruiser, as it used to be called, must remain in order to provide the outposts of the battle fleet. Their duties are, essentially, to reconnoitre and to keep the commander-in-chief informed as to its position and formation until battle is joined, after which they would close in and, acting as semi-independent squadrons, seize every opportunity to counter attacks by enemy light craft and to harry his aircraft carriers. These latter are a new fleet unit which may produce a novel and powerful influence on fleet tactics of the future. In suitable weather conditions, aircraft can take over a great deal, if not all, of the reconnaissance work of cruisers. Observation from the air may be the means of effecting a junction between rival fleets, or of enabling a weaker fleet to evade action altogether. It may be the means whereby an admiral may attain an overwhelming tactical advantage over a less well-served adversary. It may assist him to waylay and bring to action an evasive enemy, like the German fleet at Jutland. It may enable gunfire to be directed efficiently at a range so great that it would be impossible accurately to observe the fall of shot from the control tops of the ships, themselves. In addition, aircraft have enhanced the torpedo menace by introducing it in a new form. Flying from the deck of a carrier, out of sight of the hostile fleet, a torpedo-carrying squadron may appear out of the mist or from behind a smoke screen with but little warning, dive down and release their torpedoes at almost point blank range. This is a form of torpedo attack against which a sure means of defence is not very easily devised.

On the other hand the aircraft carrier constitutes a new weakness, as well as a new menace. Huge vulnerable vessels, they must suit their course to the wind when flying off their aircraft. This may lead them away from the cover of their battle fleet and expose them to the attack of enemy light forces or bombing and torpedo aeroplanes. The protection of his aircraft carriers must add appreciably to the anxieties of the commander-in-chief in battle, and the tendency of this new factor in naval war seems likely to be to complicate tactics more than ever. The destroyer, like the cruiser, is likely to hold her own as a necessary type of unit until the time arrives, if it ever does, when aircraft can function as surely as surface craft under all conditions of weather and light. Then, and only then, are we likely to see that tremendous metamorphosis in naval tactics and in naval construction which imaginative writers on air matters are wont to prophesy.

Two aspects of naval tactics have given rise to considerable controversy: the amount of freedom of action to be allowed to individual squadrons and units, and the extent to which a fleet should be divided in order to round up a retreating enemy or to concentrate on his van, rear or flank. The matter is one which has decreased in importance with the reduction in number of units in the battle fleet rendered obligatory by the Washington agreement. But in case of a long war when this agreement would no longer operate and additional battleships might be built, it is conceivable that the problem might assume something of the proportions which it did at Jutland.

There can be very little question but that officers commanding squadrons of light cruisers or flotillas of destroyers should be given very considerable latitude in order that they may make the most of opportunities which present themselves. The same may be said with regard to battle cruisers which have greatly superior speed to an enemy's battle fleet. But in the case of the battle fleet itself, experience has shown that, except where a division has very marked superiority of speed, it is exceedingly dangerous for part of the battle line to break away and indulge in independent tactics, as this involves grave risk of the enemy being able to concentrate on one part or the other with his whole

force. In principle the same arguments apply to individual ships, but circumstances may arise, particularly in the case of light craft at night, where the individual encounter may demand independent action. Nevertheless, whatever degree of licence is given to or assumed by subordinate commanders, they must at all times be guided by the main tactical plan or strategical aim of the commander-in-chief. For instance, at Jutland (*q.v.*) it was Admiral Jellicoe's object to manoeuvre the Grand Fleet into a position between the enemy fleet and its line of retreat to their base. With the able co-operation of the flag officers and captains under his command this object was finely attained. But if part of the battle fleet had launched out on an independent course of action with a view to harrying the enemy on the opposite side, under the conditions of low visibility which prevailed, it would have been out of touch with the main fleet, and this might have caused the commander-in-chief serious embarrassment. The only exception that can be made to this statement is the case of the fast division of "Barhams" (reduced to three ships soon after the main action was joined) whose speed was sufficient to enable them to draw away from the enemy's battle fleet at any time, while they were so powerful that they had nothing to fear from the faster enemy battle cruisers. It is not possible to dogmatise on the subject of naval tactics; so much must depend on circumstances, but it can be said confidently that the keynote of success in a fleet action will be in the future, as it has been throughout the ages, that co-operation between all commands which springs from complete mutual understanding and inspiring leadership.

NAVAN, a market town of co. Meath, Ireland, situated at the confluence of the Blackwater with the Boyne. Pop. (1926) 3,649. Here the Clonsilla and Kingscourt branch of the Great Southern railway crosses the Drogheda and Oldcastle branch of the Great Northern. By the former it is 30 m. N.W. of Dublin. Navan has considerable trade in corn and flour, some manufacture of woollens and of agricultural implements, and a tannery. It was a barony of the palatinate of Meath, was walled and fortified, and was incorporated by charter of Edward IV. It suffered in the civil wars of 1641. It is a favourite centre for rod-fishing.

NAVARINO, BATTLE OF, fought on Oct. 20, 1827. By the treaty signed in London on July 6, 1827 (*see GREECE, History*), England, France and Russia agreed to demand an armistice, as preliminary to a settlement. Sir Edward Codrington, then British commander-in-chief in the Mediterranean, received the treaty on the night of Aug. 10 at Smyrna, together with instructions to demand an armistice, and to intercept all supplies coming to the Turkish forces in the Morea. He at once proceeded to Nauplia to communicate with the Greeks, accompanied by his French colleague, Rear-admiral de Rigny. The Greek Govern-

ment agreed to accept the armistice. Admiral de Rigny left for a cruise in the Levant, and Sir Edward Codrington, hearing that an Egyptian armament was on its way from Alexandria, found it, together with a Turkish squadron, at anchor at Navarino on Sept. 12. The Turkish Government refused to accept the armistice, but on the 25th an interview took place between Codrington, de Rigny, who had just arrived, and Ibrahim Pasha on behalf of the sultan, at which Ibrahim gave a verbal engagement not to act against the Greeks pending further orders. The allies, who were in want of stores, now separated again, Codrington going to Zante and de Rigny to Cervi, frigates being left to watch Navarino. The British admiral had barely anchored at Zante before he was informed that the sultan's forces were putting to sea. From Oct. 3 to 5 Codrington, who had with him only his flagship the "Asia" (84) and some smaller vessels, was engaged in turning back the Egyptian and Turkish vessels, a task in which he was aided by a violent gale. He resumed his watch off Navarino, and on the 13th was joined by de Rigny and the Russian squadron under Rear-admiral Heiden. By agreement among the Powers the command was entrusted to Codrington. The allied force consisted of three British, four French and four Russian sail of the line, and a total of 15 frigates, brigs and schooners. The Egyptians and Turks had three ships of the line and 15 large frigates, together with a swarm of small craft making a total of over 80. Ibrahim Pasha, though unable to operate at sea, considered himself at liberty to carry on the war by land, and his men were employed in burning the Greek villages. On Oct. 17 a joint letter of expostulation was sent to Ibrahim, but was returned with the manifestly false answer that he had left Navarino. The admirals, therefore, decided to stand into the bay. A French officer in the Egyptian service, named Letellier, had anchored the vessels of Ibrahim and the Turkish admiral in a horseshoe formation, of which the points touched the entrance to the bay, and there were forts on the lands at both sides of the entry. The allies entered in two lines and began to anchor in the midst of Ibrahim's fleet. Captain Fellowes, commanding the British frigate "Dartmouth," seeing a Turkish fireship close to windward of him, sent a boat to demand that she should be removed. The Turks opened fire on the boat, and the action at once became general. The result was obtained by heavier broadsides and better gunnery. Three-fourths of the Turkish and Egyptian vessels were sunk or fired by their own crews. The allied casualties were 177 killed and 519 wounded. The loss of the Turks and Egyptians was never accurately reported.

See Lady Jane Bouchier, *Memoir of the Life of Admiral Sir E. Codrington* (1873). (G. A. R. C.; W. C. B. T.)

NAVARRÉ, a province of northern Spain, and formerly a kingdom which included part of France. The province is bounded on the north by France (Basses Pyrénées) and Guipúzcoa, east by Huesca and Saragossa, south by Saragossa and Logroño and west by Álava. It is traversed from east to west by the Pyrenees and the Cantabrian Mountains. Pop. (1920) 329,875. From Navarre there are only three practicable roads for carriages into France—those by the Puerta de Vera, the Puerta de Maya and Roncesvalles. The highest summit is the Monte Adi (4,931 feet). The chief river flowing towards the Atlantic is the Bidasoa, which rises near the Puerta de Maya. After flowing southwards through the valley of Baztán it takes a north-easterly course, and for a short distance above its outfall at Fuenterrabia constitutes the frontier between France and Spain (Guipúzcoa); by far the larger portion of Navarre is drained to the Mediterranean through the Ebro, which flows along the western frontier and crosses the extreme south of the province. The hilly districts consist almost entirely of forest and pasture, the most common trees being the pine, beech, oak and chestnut. Much of the lower ground yields grain; the principal fruit is the apple, from which cider is made in some districts; hemp, flax and oil are also produced, and mulberries are cultivated for silkworms. Navarre is one of the richest provinces of Spain in live stock. Game is plentiful.

The Ebro Valley railway traverses southern Navarre and skirts the western frontier. It has several branch lines. Besides Pamplona (*q.v.*), the capital, the only towns with more than 5,000

inhabitants are Baztán (9,676), Corella (6,830), Estella (5,603) and Tafalla (5,829).

HISTORY

The kingdom of Navarre was formed out of a part of the territory occupied by the Vascones, *i.e.*, the Basques and Gascons, who occupied the southern slope of the western Pyrenees and part of the shore of the Bay of Biscay. In the course of the 6th century there was a considerable emigration of Basques to the north of the Pyrenees. The cause is supposed to have been the pressure put upon them by the attacks of the Visigoth kings in Spain. The name of Navarre is derived by etymologists from "nava" a flat valley surrounded by hills and "erri" a region or country. It began to appear as the name of part of Vasconia towards the end of the Visigoth epoch in Spain in the 7th century. Its early history is more than obscure. The first historic king of Navarre was Sancho Garcia, who ruled at Pamplona in the early years of the 10th century. Under him and his immediate successors Navarre reached the height of its power and its extension (*see* SPAIN: *History*, for the reign of Sancho el Mayor, and the establishment of the Navarrese line as kings of Castile and Leon, and of Aragon). When the kingdom was at its height it included all the modern province of the name; the northern slope of the western Pyrenees called by the Spaniards the "Ultra-puertos" or country beyond the passes, and now known as French Navarre; the Basque provinces; the Bureba, the valley between the Basque Mountains and the Montes de Oca to the north of Burgos; the Rioja and Tarazona in the upper valley of the Ebro. In the 12th century the kings of Castile gradually annexed the Rioja and Álava. While Navarre was reunited to Aragon—1076–1134—(*see* SPAIN: *History*) it was saved from aggression on the east, but did not recover the territory taken by Castile. About the year 1200 Alfonso VIII. of Castile annexed the other two Basque provinces, Biscay (Vizcaya) and Guipúzcoa. Tarazona remained in possession of Aragon. After 1234 Navarre, though the crown was claimed by the kings of Aragon, passed by marriage to a succession of French rulers. In 1516 Spanish Navarre was finally annexed by Ferdinand the Catholic. French Navarre survived as an independent little kingdom till it was united to the crown of France by Henry IV., founder of the Bourbon dynasty. From 1510 until 1833, when it was fully incorporated with Spain, Navarre was a viceroyalty.

See Don J. M. Yanguas, *Historia Compendiada de Navarra* (San Sebastian, 1832); J. F. Bladé, *Les comtes carolingiens de Bigorre et les premiers rois de Navarre* (1895–97).

NAVARRETE, JUAN FERNANDEZ (1526–1579), surnamed El Mudo (The Mute), Spanish painter of the Madrid school, was born at Logroño in 1526. An illness in infancy deprived him of his hearing, but at a very early age he began to express his wants by sketching objects with a piece of charcoal. He received his first instructions in art from Fray Vicente de Santo Domingo, a Hieronymite monk at Estella, and afterwards he visited Naples, Rome, Florence and Milan. According to the ordinary account he was for a considerable time the pupil of Titian at Venice. In 1568 Philip II. summoned him to Madrid with the title of king's painter and a salary, and employed him to execute pictures for the Escorial. The most celebrated of these are a "Nativity" (in which, as in the well-known work on the same subject by Correggio, the light emanates from the infant Saviour), a "Baptism of Christ" (now in the Madrid Picture Gallery), and "Abraham Receiving the Three Angels" (one of his last works dated 1576). He died at Toledo in February 1579.

NAVARRO, PEDRO (c. 1460–1528), Spanish military engineer and general. Beginning as a sailor, he became *mozo de espuela*, or running footman, to the cardinal Juan de Aragon. In 1485 he enlisted as a mercenary in a war between Florence and Genoa, and took part in the warfare between the Genoese corsairs and the Mohammedans of northern Africa. He enlisted under Gonzalo de Córdoba when he sailed to Sicily, to take part with the French in the partition of Naples, and in 1500 he laid mines to breach the walls at Cephalonia without much success. He distinguished himself in the campaigns of 1502–03, by the defence of Canosa and of Taranto and by his share in the victory

at Cerinola. His mining operation against the castles of Naples, held by French garrisons, in 1503, won him fame as the first military engineer of his age. At the expulsion of the French from Naples, he received from Gonzalo a grant of land and the title of count of Olivetto. In 1508 he took Velez de Gomera, largely by means of a species of floating battery which he invented. He did excellent service in the conquest of Oran (1509), and took Bougie and Tripoli in 1510. At Ravenna he covered the orderly retreat of the Spanish foot, was taken prisoner by the French and imprisoned in the Castle of Loches. Ferdinand, "the Aragonese skinflint," refused to pay his ransom, and after three years of imprisonment, Navarro entered the service of Francis I. in a pique. He distinguished himself in the passage of the Alps, at Marignano, at Milan, and in the siege of Brescia. He was at the battle of Pavia, and in 1522 was taken prisoner at Genoa by the Spaniards. He was confined at Naples till the peace of 1526 and his Olivetto estate was confiscated. His last service was in the disastrous expedition of Lautrec to Naples (1527).

See *Documentos inéditos para la Historia de España*, vol. xxv. (Madrid, 1854).

NAVASOTA, a city of Grimes county, Texas, U.S.A., in the south-eastern part of the state, 72 m. N.W. of Houston, near the Brazos river. It is served by the Gulf, Colorado and Santa Fe, the Missouri Pacific and the Southern Pacific railways. Pop. (1920) 5,060 (49% negroes), estimated locally at 6,000 in 1928. It has cotton gins and cottonseed-oil mills, and is a shipping point for cotton, grain, pecans and other agricultural products. The city was settled about 1820, and incorporated in 1866.

NAVE, ecclesiastically considered, that part of a church appropriated to the laity as distinguished from the chancel, the choir or the presbytery, reserved for the clergy. In a 14th century letter (quoted in Gasquet's *Parish Life in Medieval England*, 1906, p. 45) from a bishop of Coventry and Lichfield to one of his clergy, the reason for this appropriation is given. "Not only the decrees of the holy fathers but the approved existing customs of the Church order that the place in which the clerks sing and serve God according to their offices be divided by screens from that in which the laity devoutly pray. In this way the nave of the church . . . is alone to be open to lay people, in order that, in the time of divine service, clerics be not mixed up with lay people, and more especially with women, nor have communication with them, for in this way devotion may be easily diminished." The word "nave" has been generally derived from Lat. *navis*, ship. Salmasius in his commentary on Solinus (1629) finds the origin in the resemblance of the vaulted roof to the keel of a ship. The use of the word *navis* may, however, be due to the early adoption of the "ship" as a symbol of the church (*see* Skeat's note on *Piers Plowman*, xl. 32). The Greek *naós*, Attic *naós* (*naiein*, to dwell), the inner shrine of a Greek temple, the *cella*, has also been suggested as the real origin of the word. This derivative must presume a latinized corruption into *navis*, for the early application of the word for ship to this part of a church building is undoubted.

Architecturally considered the nave is the central and principal part of a church, extending from the main front to the transepts, or to the choir or chancel in the absence of transepts. When the nave is flanked by aisles light is admitted to the church through clerestory windows. (*See* BYZANTINE AND ROMANESQUE ARCHITECTURE.) At times, however, a gallery was carried above the side aisles.

NAVEL, in anatomy, the umbilicus, the depression in the abdomen which indicates the point through which the embryo mammal obtained nourishment from its mother. (*See* ANATOMY: *Superficial and Artistic*.)

NAVIGATION. The science or art of conducting a ship across the sea. The term is also popularly used in connection with boats on rivers and lakes and with flying-machines, although in this latter case the science is often and correctly termed air-navigation. Navigation is technically limited to the art of conducting a ship from one port to another across, and on the surface of, the open sea, and it is in this technical sense that the subject is dealt with below.

Historical.—Before the introduction of the mariners' compass

in the 14th century, the only practical means, among western nations, of navigating ships was to keep within sight of land; or to steer for short distances out of sight of land by reference to the sun or stars, more particularly the pole star. In eastern waters, long voyages out of sight of land were possible owing to the steadiness in direction of the monsoons, which enabled vessels in these localities to keep their course by running directly before the wind. The act of fixing positions by astronomical methods progressed far more rapidly on shore than at sea. The few rude appliances available to the navigator were limited, until the 18th century, to finding only the latitude of the ship at sea. No means of finding the longitude was devised, except the very rough method of estimating the run of the ship—known as dead reckoning—until the introduction, for practical purposes, of the lunar problem early in the 18th century. This complicated calculation made the finding of longitude one of considerable difficulty, even after the introduction of the sextant; because the moon passes the stars lying in her course through the heavens at a mean rate of only 33" in one minute of time, and her motion in regard to the sun being less than this, it is obvious that a very small error in measuring the distance produces a correspondingly large error in the resulting longitude. The rise of what may be termed modern methods of astronomical navigation may be fairly dated from the invention of the chronometer in 1735, although it was not until some 40 years later that extensive trials of Harrison's chronometer proved to navigators the value of this instrument. The method of finding the apparent, or sun, time at the ship's position was well-known; but until the chronometer came into use afloat, and enabled the navigator to carry Greenwich mean time with him on board, it was not possible to find the longitude by simple calculation. (See CHRONOMETER.)

Rapid strides were made in the 19th century in the improvement of instruments and the publication of text-books useful to the navigator; also in the production of tables of logarithms compiled to facilitate the solution of trigonometrical problems associated with navigation. The *Nautical Almanac*, first published under authority for the use of seamen in 1767, came into general use. Machines for taking soundings were introduced and various methods were invented whereby the errors of the magnetic compass, due to the permanent and induced magnetism in the iron of the ship, could be very largely eliminated. Methods were applied whereby that important factor in obtaining an accurate position, the speed of the ship through the water, could be serviceably ascertained. The introduction of steam vessels went far to simplify the problems of navigation as the dead reckoning could be calculated with greater accuracy than was the case with sailing vessels. The progress of the art of navigation was, and is, of course, still inseparably connected with chart drawing. The steady and continuous improvement in the number and accuracy of charts is due to the marine hydrographic and coast survey service conducted by the principal maritime nations.

Modern Navigation.—With the above brief summary of the progress of navigation, the methods in use at the present time will be described, referring the reader for a more detailed and technical description to the text-books available on the subject. When making a passage from port to port situated at no great distance apart, the navigator ordinarily selects a course on a Rhumb line, which, on a Mercator's chart, the chart normally used, is a straight line. Between ports situated at great distances from one another, and differing widely in longitude, the course followed should be on the Great Circle, which, on a Mercator's chart is a curve, the shortest distance between any two places on the surface of the earth.

Time at Sea.—To avoid confusion a system of time zones for time-keeping at sea is in force in the navies of most countries. This system has been adopted so that vessels at sea, within certain defined limits of longitude, shall keep the same time as that used on land. The world is longitudinally divided into 24 zones of 15° each, the centre of the system being the meridian of Greenwich. This centre division lies between the meridians of the 7½° E. and 7½° W. and is known as the zero zone, or zone 0; the zones lying to the eastward being numbered in sequence with a minus (—) prefix; those to the westward being similarly numbered with

a plus (+) prefix. The limits of the zones on land are modified somewhat according to the geographical configuration of the country concerned. By this system the same time is kept whether on land or sea throughout each zone except during the periods of summer time. The term Greenwich mean time (G.M.T.) is considered to be the standard time of the meridian of Greenwich, commencing at midnight and reckoned throughout the 24 hours. Both civil and astronomical times are, therefore, reckoned from midnight instead of from midnight and noon respectively. In the *Nautical Almanac* (abridged for the use of seamen) for 1925, and following years, the elements which prior to 1925 were given for every two hours of the astronomical day, which then began at noon, are given for every two hours of G.M.T. commencing at midnight.

Astronomical Navigation.—When considering the various methods of fixing the position of a ship at sea by observations of heavenly bodies, it is assumed that the errors of the chronometers are accurately known. Although chronometers have reached a high standard of efficiency they are nevertheless subject to very slight variations in respect to the true Greenwich time. The introduction of wireless time signals enables navigators in ships fitted with wireless telegraphy to obtain accurate time daily in most parts of the world. There are over 50 stations, working on various wavelengths and situated in different countries, for transmitting these signals. It is desirable to refer to the relevant publications for details of the form of transmission, and procedure.

Assuming then, that the true Greenwich time is calculated; that the observer is competent and the instrumental errors are known, the accuracy of a sea position, obtained by the observation of heavenly bodies, depends mainly on the accuracy of the sea horizon. On account of abnormal refraction occasioned by special conditions in the atmosphere, the sea horizon, as seen by an observer, is often displaced from the position which the tables of normal dip of the horizon would assign to it. This refraction is most common in localities where the temperature of the air and water differ widely. By combining the results obtained from observation of bodies situated in opposite quarters of the horizon, the errors in finding the true position of the horizon are largely counteracted. The conditions at dawn and twilight, when the horizon is visible and suitably placed stars can be selected, lend themselves to this purpose. And, moreover, it is in these periods that opportunities are present for another important purpose, that is, the selection, for simultaneous observation, of bodies whose relative bearings are such that the lines of position determined from the observations shall afford a well defined intersection, and thus serve to accurately find the latitude and longitude at approximately the same instant.

The only information that is obtained from one observation of a heavenly body is that the ship is somewhere on the circumference of a small circle, on the earth's surface, the centre of which is the geographical position of the body and the radius of which has the same arc-measure as the zenith distance at the instant of observation. At this instant the heavenly body observed must be vertically over some one point on the surface of the earth. The latitude of this point is equal to the declination of the body and the longitude is equal to the hour angle of the body from the meridian of Greenwich.

Owing to the size of the globe which would be required, it is, of course, not practicable to plot this small circle on a globe, and plotting it on a chart is inconvenient unless the radius is very short and the ship in low latitude. A small circle becomes very greatly distorted when plotted on a Mercator's chart, unless near the Equator. The usual method of plotting, on a chart, is to represent a portion of the small circle as a straight line, a tangent to the circumference; that is, a straight line drawn at right angles to the bearing of the body observed. But, as a straight line represents accurately only a very small portion of the circumference of a circle, it is necessary to select some point through which to draw this line, as near the actual position of the ship as possible. This straight line is the "line of position" somewhere on which the ship must be. If another heavenly body, suitably placed, is now observed or, after a reasonable interval, to allow of a change of

bearing, a second observation of the same body is made, a second line of position is obtained. The intersection of these two lines of position gives the actual position, provided the first line of position has been moved parallel to itself to allow for any run of the ship in the interval. The line of position, being a tangent to the small circle, is at right angles to the radius or bearing of the body observed; it follows, therefore, that the angles at which the several lines of position will intersect one another must be the same as the angles at which the bearings intersect. Bodies should, therefore, be selected which will give a good "cut." Each line of position has precisely the same value, provided the altitude has been observed with equal accuracy. An error of 1' in the observed altitude, and thence in the zenith distance, produces an error of one mile in the line of position.

Now as to the manner of obtaining the point through which to draw the line of position. Whatever method is used, provided the method is a correct one, the point found will be somewhere on the line of position. There can be only one line of position derived from the observation of one body. Different methods of calculation do not give different lines of position, but give different points through which the line of position can be drawn. A point can be found by assuming the latitude and calculating the resulting longitude, which is a procedure applicable to observations of heavenly bodies which have a large azimuth; or by assuming the longitude and calculating the resulting latitude, which is applicable to observations of bodies with a small azimuth. The best method, however, is to assume both latitude and longitude and, therefrom, to calculate the zenith distance of the body observed, or in other words, the radius of the circle of position. Having, at the same instant, observed the actual altitude, and thence the zenith distance, it is at once ascertained whether the ship is on a line which is directly nearer to or directly farther from, the geographical position of the body than the assumed or dead reckoning position.

MODERN AIDS TO NAVIGATION

Directional Wireless.—Determining the position of a ship at sea by means of directional wireless telegraphy (*see* WIRELESS) is of inestimable value to ships in thick weather, when approaching the land. The bearing of the shore station from the ship can be obtained either by means of a directional receiving apparatus carried in the ship, or by the system whereby the bearing of the ship is determined by one or more directional receiving sets on shore and the result being communicated to the ship.

The method of receiving bearings from ashore has the advantage that no additional equipment outside of the ship's ordinary wireless equipment is needed. However, it is subject to the disadvantage that the navigator himself cannot take and check the bearings. Furthermore, the shore stations can give a bearing to only one ship at a time which prevents a constant, repeated check of the ship's position. On the other hand the method of carrying the directional receiving set in the ship, once considered an interesting novelty, has been widely accepted as a necessary aid to navigation. The advantages of this method can be readily appreciated. For the navigator can repeatedly check his bearings upon the shore station with no wait except for the momentary pause in the code signals characteristic of that particular shore station. A knowledge of telegraphy is not required to receive the code signals, and the operation of the ship's wireless direction finding equipment is practically simple.

Either method of course is dependent upon the establishment of wireless direction finding (D/F) stations at points of importance to navigators.

The accuracy of the bearings is affected somewhat when the direction runs approximately parallel to the coast-line. Also bearings sometimes have been found to be unreliable at night. Wireless waves travel along the arc of a great circle as the shortest distance between any two points on the surface of the earth. It follows, therefore, that the true bearing of the ship from the station, or vice-versa, must be corrected for convergency to obtain the mean mercatorial bearing which is required if a chart on Mercator's projection is in use. A simple formula given in text-books enables this to be done. On a chart constructed on the gnomonic

projection D/F bearings can be laid down without any correction for convergency, since great circles appear as straight lines on this projection. If, however, a compass "rose" is used it is necessary to have one on the chart for each D/F station, to compensate for the angular alteration of the projection at that station.

Sound Ranging.—Sound ranging (*see also* SOUNDING) also enables the position of a ship to be determined with accuracy at a considerable distance from the land.

Echo Sounding.—(*See* SOUNDING), by which the depth of water is obtained by the acoustic method, is of value in cases where the depth of water, or the speed of the ship, makes sounding by direct measurement unreliable. To obtain an accurate sounding by this method, a complete and sensitive apparatus is required. The apparatus consists of two microphones, one of which registers the emission of a sonic signal and the other the arrival of the echo reflected by the bottom of the sea. A specially constructed time recorder capable of reading to one-thousandth part of a second is connected to the microphones and enables the depth to be deduced. Sound travels through sea water at an average velocity of 4,800ft. per second. Consequently, by the acoustic method, very great depths can be reached in a brief space of time and the depths nominally required for navigational purposes will be reached in a small fraction of a second.

The highest practical development of the echo sounding principle is a device named the *Fathometer*. (*See* FATHOMETER.)

The Leader System.—The Leader system assists vessels to enter or leave harbour or to pass through narrow channels in thick weather. A submarine electric cable is laid along the channel, the shore end being connected to a station producing an alternating current. A simple and inexpensive receiving apparatus on board the ship enables the signals to be heard in telephones, or other form of amplifier, placed at or near the position from which the ship is usually conned. Two sets of coils are fitted, one on either side of the ship and so arranged that they can each be connected up to the receiving telephones. By connecting first one set of coils and then the other, to the receiving telephones, it is an easy matter, when within range, to determine whether the cable is to port or starboard. With practice, the distance of the cable can be estimated with comparative accuracy, because the signals become stronger as the cable is approached, the maximum intensity of the signals occurring when the ship is close to, but not vertically over, the cable. The same cable enables one ship to enter and one to leave harbour at the same time, provided, of course, the navigable channel is of sufficient width; it is a simple matter for each ship to steer to keep the cable a reasonable distance away on her port side, so that the two ships pass safely port to port. If space permits, it is possible to lay two cables, one for entering and one for leaving, the signals produced in each cable being distinctive by their note and character. This system has not come into general use owing presumably to the somewhat heavy cost.

Macdonald, *Macdonald's Tables for Correcting Wireless Bearings from Latitude 5 deg. to 70 deg. North or South* (1922); Captain Lecky, *Wrinkles in Practical Navigation* (13th ed., 1927); L. M. Berkeley, *Great Circle Sailing* (1924) and *North Star Navigation* (1925). (J. E. T. H.)

NAVIGATION LAWS. Historically this expression refers to laws passed at various times and places to restrict commerce to ships of a particular nationality, but, in another sense, navigation laws are those which lay down rules of the road and in other ways regulate the actual navigation of ships. With these latter all ships are as a rule required to comply, whatever their nationality. The two classes will here be dealt with separately.

Restriction of Navigation.—In England the first Navigation act was passed in 1381, during the reign of Richard II. Policy varied from time to time until the 17th century. Then, in 1651, during the period while Oliver Cromwell was in power, the Navi-

SCIENTIFIC NAVIGATION AIDS

1. Officers on the bridge of the S.S. "Da Grasse," determining the ship's position by means of sextants, through which the sun is sighted. 2. Wheelhouse of the S.S. "California," showing, to the left, the gyro-compass which controls the rudder wheel on the right, automatically holding the ship on a predetermined course. The gyro-compass is visible above the small handwheel at the left of the photograph. 3. Radio position finder on the S.S. "California." The bearing of a shore station, from which wireless signals are being sent, is accurately determined on board ship by means of the directional receiving apparatus shown. 4. Navigating room of the S.S. "Ile de France." The loud-speakers, on vertical position, are used in establishing rapid communication between the bridge and other portions of the ship, serving as great aids to navigation. The hand-controlled steering wheel, shown in centre, was later supplemented by gyro-pilot control. 5. Radio position finder on the S.S. "Ile de France." As in the type of fig. 3, the direction from which the land signals are being sent is ascertained by determining from what point of the compass signals are received with maximum intensity.

gation act was passed in order to strike a blow at the maritime supremacy of the Netherlands. The system set up of requiring the national trade by sea to be carried in ships under the national flag was maintained in force (as varied and amended by a number of further statutes) for a period of two centuries. By the Navigation acts ships under the national flag were required to be owned by British subjects, and shipmasters, and a proportion of the seamen were also required to be British.

"Under the form the Navigation acts had assumed in 1847 no produce of Asia, Africa or America could be imported for consumption into the United Kingdom from Europe in any ships, the object being that the trade should be direct and in British bottoms. The whole of the coasting trade of the United Kingdom was restricted to British ships, and the colonial trade was prohibited to all foreign ships unless under the sanction of a special Order in Council. Various restrictions were imposed on imports except in British ships. Differential dues and restrictions on importations could be imposed by Order in Council on the ships of any foreign country which imposed similar restrictions on British trade. It is to be observed that, with the exception of restrictions on exportation from this country to certain British possessions, the prohibitions of the Navigation acts were entirely restricted to imports. This necessarily followed from certain important trading powers having anticipated Great Britain in the enactment of navigation laws, their refusal to receive our goods except in their own ships preventing the possibility of the British parliament effectually restricting exportation in this direction." (Pulling.)

By an act passed in 1849 (12 & 13 Vict. C. 29) the Navigation laws were repealed, subject to a reservation of the coasting trade, and to a provision, intended to secure reciprocity, whereby, if British ships were subjected in other countries to prohibitions or restrictions, the privilege of the ships of those countries in British ports might be restricted.

Foreign ships were admitted to the coasting trade of the United Kingdom by an act passed in 1854 (17 & 18 Vict. C. 5) the provisions of which have been re-enacted in the Customs Consolidation act 1876, section 141.

While the laws restricting trade to national ships have thus long ceased to operate, British Law still provides that a ship shall not be deemed to be a British ship unless owned wholly by British subjects, or by a body corporate established in some part of the King's Dominions. British ships are required to be registered as such (Merchant Shipping acts). Further, by the British Nationality and Status of Aliens act 1914, an alien cannot be the owner of a British ship, and, by the Aliens Restriction (Amendment) act 1919, no alien may act as the master or as one of the principal officers of a British ship.

In the United States a system of duties discriminating against foreign ships was adopted in 1789. Under various statutes provision was made for relief by way of reciprocity, and consequently, after 1849, British ships were admitted to United States ports on the same terms as American ships were admitted into British trade, but coastwise trade has continued to be limited to ships of the United States.

The treaties of peace entered into at the conclusion of the World War laid down that steps should be taken to secure and maintain freedom of communications and of transit and equitable treatment for the commerce of all members of the League of Nations. At conferences convened by the League several international conventions on these lines were adopted. These included the Maritime Ports convention under which each of the contracting parties undertook, subject to the principle of reciprocity "to grant the vessels of every other contracting State equality of treatment with its own vessels, or those of any other State whatsoever, in the maritime ports situated under its sovereignty or authority, as regards freedom of access to the port, the use of the port, and the full enjoyment of the benefits as regards navigation and commercial operations which it affords to vessels, their cargoes and passengers. The equality of treatment thus established shall cover facilities of all kinds, such as allocation of berths, loading and unloading facilities; as well as dues and charges of all kinds levied in the name or for the account of the Government,

public authorities, concessionaries or undertakings of any kind."

This Maritime Ports convention, however, does not apply to maritime coasting trade. The conference at which the convention was adopted passed a resolution recommending that all States should refrain from inequitable economic measures, such as in particular an abusive extension of the scope of the maritime coasting trade. The representatives of nearly 40 countries took part in this conference and the representatives of the United States attended as observers.

Regulation of Navigation.—The other class of navigation laws laying down rules of the road and in other ways regulating the actual navigation of ships may apply (1) on the high seas, or (2) within territorial waters, ports, harbours, docks and inland navigable waters. (As to territorial jurisdiction in general see *WATERS, TERRITORIAL*.)

Customary rules of seamanship applicable to navigation on the high seas were gradually developed. In England the Trinity Masters advised the judges as to the rules by which those in charge of a ship should be guided. In 1846 some Trinity House rules of navigation were made statutory. In 1889 an international maritime conference took place at Washington, the ultimate outcome of which was the drawing up of the international regulations for preventing collisions at sea. These have been adopted by all maritime nations, and are thus of universal application. They are operative in respect of British ships everywhere and in respect of foreign ships when within British jurisdiction in the following way. The British Merchant Shipping acts empower the King, by Order in Council, to make regulations of this kind. This was done in 1896. Several further orders were made, and in 1910 the regulations were consolidated and reissued in the form in which they are now in force.

The collision regulations apply in general everywhere but they are subject in certain harbours and inland waters to qualifications introduced by local rules to adapt them to special local circumstances. These were made either in the same way as other national laws or by local authorities under powers given to them by the national legislature having jurisdiction over the place in question. Thus local rules are in force in many British and Irish ports and waterways, in the Danube and port of Sulina, in the Scheldt, at Gibraltar, in the Suez Canal, in United States inland waters and in the Great Lakes, both United States and Canadian.

Maxwell, *Discriminating Duties and the American Merchant Marine* (1926). (Regulation) : G. Kaackenbeeck, *International Rivers* (London, 1918) ; E. S. Roscoe, *Admiralty Practice* (1920) ; Marsden's *Collisions at Sea* by A. D. Gibb (London, 1923). (S. D. C.)

NAVY AND NAVIES. Originally the navy of a country meant the whole of its shipping, whether used for war, the carrying of merchandise or fishing. In modern parlance, however, the word is generally taken to mean a nation's warships and craft of every kind maintained for fighting on, under or over the sea and the personnel which mans them, e.g., the British Navy consists of the surface warships,—battleships, cruisers, aircraft carriers, destroyers, mine-layers, mine-sweepers, gun-boats and other auxiliary craft; the submarines; and the fleet air arm. Behind the actual fighting units there is, necessarily, a vast organization for their administration and upkeep. See the sections "Defence" of the articles UNITED STATES, FRANCE, GERMANY and other countries; also such articles as ADMIRALTY, STAFF, NAVAL AND DOCK YARDS and NAVAL BASES.

History of Navies.—In early history we find navies in the form of the armed men of a tribe or town putting to sea in such large boats or ships as might be available to give battle to enemies similarly equipped or to raid territory from the sea. The craft themselves were for the most part those used for commerce, fishing or, when occasion served, for war or piracy. It was the exception that they were built especially for fighting purposes. But later we see special types of war craft designed as such beginning to assume a recognized place in the armory of peoples and their sovereigns. Some of the earliest of what we should, to-day, term sea powers were the Phoenicians, Athenians, Carthaginians, Romans, Norsemen, Venetians, French and early English, but navies

in legendary form are to be found 2,000 years before they materialised in accredited records and the adventures of the Argonauts and of Ulysses would seem poetic forecasts of the age of the Vikings. In regard to the vessels themselves, there are definite indications of long ships built for speed as distinguished from round ships for burden from the time of the ancient Greeks and Romans. The Athenian navy was a state force and in 483 B.C. the threat of Persian attack caused Athens to increase her fleet from 50 to 100 long ships which were paid for out of the proceeds of the mines of Laureium (see THEMISTOCLES). The effect of this was to make Athens the predominating partner in the league formed by the Greeks for their common naval defence. By the end of the 5th century B.C. the fleet had increased to 300 long ships and later to as many as 360. In peace these war vessels were kept on slips and under cover in sheds; in war a *strategos* was appointed in command and he chose the trierarchs who were deputed to commission the vessels, partly at their own expense, under the supervision of State Inspectors.

In general the organization of the Athenian navy resembled closely that of the British navy in the 16th and 17th centuries. The trierarch, who was either one of a group of citizens assisting to finance one or more war vessels, or someone paid to discharge the duty, answered to the captain; there was a sailing master; a number of petty officers; seamen and oarsmen; while soldiers or marines formed the fighting personnel. The most ancient warships were many-oared galleys (*q.v.*), each requiring a very large number of rowers. The result was that the personnel provided to man a fleet of those times had to be a considerable one. For instance, the Roman and Carthaginian forces in the first Punic War numbered approximately 150,000 men on each side. These great rowing galleys relied for their offensive powers on boarding or ramming, and we see them in great numbers in the Mediterranean as the war fleets of the succession of Alexander, of Carthage, of Rome, of Byzantium, of the Italian Republics, of the Arabs and of Aragon. (See also SHIP.)

In the naval organization of ancient Rome we see the beginning of the idea of an Admiralty in the navy commissioners appointed in 311 B.C. It is interesting to note, too, that the Roman Empire was faced, on a small scale, with maritime problems which have assumed such vast importance to the British Empire of to-day. Not only had Rome to maintain a fleet to neutralize the threat arising from rival sea powers, but sea-borne trade was of such importance as to compel her to provide a navy capable of dealing with prevalent piracy and the needful safeguarding of routes. This organization, which was very complete, included two main fleets which guarded the coasts of Italy at Ravenna and Misenum. These were known as the Praetorian. Other squadrons were allocated to Forum Julii, to the mouth of the Orontes, to Alexandria, to Carpathus (between Crete and Rhodes), to Aquileia (at the head of the Adriatic), to the Black Sea and to Britain. River flotillas were stationed on the Rhine and Danube and, later, on the Euphrates. All these squadrons did not exist at the same time, but there was always a highly organized navy with a body of soldiers, the *classici*, specially assigned for service afloat.

The navy of the Eastern Empire may be said to have originated with the foundation of Constantine's New Rome on the site of Byzantium. The threat of attack from the Vandal kingdom of Carthage (from A.D. 428 to 524) compelled the Emperors to attend to their fleet, but with the fall of that kingdom the navy was neglected until the rise of Mohammedan power at the end of the 7th century produced a new menace. The Byzantine navy reached a high state of efficiency under the sovereigns of the Macedonian dynasty (867-1056). It consisted of an Imperial fleet commanded by the Great Drungarios, the first recorded Lord High Admiral, and of provincial squadrons under their *strategoi*. The Imperial Fleet was essentially a war organization, while the provincial or thematic squadrons were smaller but more permanent forces maintained for police purposes. It is interesting to note that this navy included a corps corresponding to the gunnery experts of a modern fleet. These were the *siphonarioi*, who worked the *siphons* used for discharging the "Greek fire."

After the disorganization of the Eastern Empire by Turkish

invasions in the 12th century, the Byzantine navy withered. In the middle ages the Italian republics and monarchical states bordering on the Mediterranean possessed appreciable fleets, and their seamen, especially those of Genoa, were regarded as some of the first in the world, so much so that their services were sought by the powers of Western Europe and even by England. Edward III. and the kings of France employed Genoese to assist them in nautical matters.

The Mediterranean navies made their last great appearance in history at the Battle of Lepanto, 1571 (*q.v.*). From thence onwards the scene of naval activity changed and the ships and fleets took upon themselves a new form, and one to fit them for ocean sailing and fighting. The history of the growth of modern great navies will be found under their respective countries. (E. A.)

BIBLIOGRAPHY.—*Ancient and General.*—Accounts of the naval organizations of the ancient world, and of the sea fighting of the time are to be found in the histories of Greece and Rome: G. Corazzini has written a *Storia della marina militare antica* (Livorno, 1882). Valuable details of the Imperial Roman navy and of the Byzantine navy will be found in Prof. J. B. Bury's appendices to his edition of Gibbon's *Decline and Fall*, vol. i. apx. 5, and vol. vi. apx. 5 (1896-1900). There is an *Histoire de la marine de tous les peuples*, by M. A. du Sein (Paris, 1879). See also A. T. Mahan, *Influence of Sea Power on History, 1600-1783* (1890).

Mediæval.—As regards the mediæval navies the first place may be allowed to the Italians. A general bibliography of Italian nautical literature *Saggio di una bibliografia marittima italiana*, occupying fifty-eight pages, drawn up by E. Celani, will be found in the *Revista marittima*, supplement for 1894. The histories of the different Republics of the middle ages record their maritime enterprises. An excellent book, which gives far more than its title promises, is the *Storia della marina pontificia* of A. Guglielmotti, O.P., in 10 volumes published at different times, and in two editions, at Florence 1856, etc. The general maritime history of the Mediterranean in the middle ages is well illustrated in the *Memorias sobre la marina comercio y artes de Barcelona* (1779-1792) by A. Capmany. The naval enterprises of the Norsemen are dealt with in a scholarly fashion by G. B. Pepping, *Histoire des expéditions maritimes des Normands* (1826); and with newer knowledge by C. F. Keary, *The Vikings of Western Christendom* (1891).

Great Britain.—The *History of the Royal Navy to the French Revolution*, by Sir N. Harris Nicolas (1847), is unfortunately incomplete. It ends at the year 1422, but is the work of a most laborious and exact antiquary, who had been a naval officer in his youth. The administrative history of the British navy until 1660 is the subject of the *History of the Administration of the Navy and of Merchant Shipping in relation to the Navy* (1896) by M. Oppenheim—a most valuable collection of materials. *The Naval History of England* (1735) by T. Lediard, is copious and useful. *The Naval Chronology, or an Historical Summary of Naval and Maritime Events from the Time of the Romans to the Treaty of Peace 1802*, by Captain I. Schomberg (1802), contains a mass of valuable information, lists of ships, dates of construction, etc., and some administrative details. A good book is *The Naval and Military Memoirs of Great Britain 1727 to 1783* (1804) by R. Beatson, a very careful and well-informed writer who had seen some service as a marine officer. *The Naval History of Great Britain, from 1793 to the accession of George IV.*, by W. James (1827), republished with a continuation by Chamier in 1847, is a standard authority. *The History of the British Navy from the Earliest Period to the Present Time* (1863) by C. D. Yonge, contains some original matter for the naval transactions of the 19th century. *The Royal Navy*, 7 vols. (1897-1903), edited and partly written by Sir W. L. Clowes, is a compilation of unequal value. Some of Sir W. L. Clowes's coadjutors, notably Captain Mahan and Sir C. R. Markham, are of high standing and authority. *The Naval Chronicle, 1799-1818*, a magazine, contains useful matter for the Revolutionary and Napoleonic Wars. *The Naval Biographical Dictionary; life and services of every living officer* (1846), by W. R. O'Brien, is a solid book of reference. The publications of the Navy Record Society (1894 and subsequent years) contain large and valuable publications of original matter, with some reprints of old authorities, such as Sir W. Monson's *Tracts*, which were difficult of access. See also *A Short History of the Royal Navy*, by D. Hannay; *Official History of the War: "Naval Operations"* (1920, etc.); G. Callender, *The Naval Side of British History* (1924); G. F. S. Bowles, *The Strength of England* (1926).

France.—Léon Guérin, *Histoire maritime de la France* (1844). *Thé Histoire de la marine française de Le Comte de Bonifils Lablénie* (1845), a naval officer, is of value. *La Marine de guerre, ses institutions militaires depuis son origine jusqu'à nos jours*, by Capne Gougeard (1877); *l'Essai sur l'histoire de l'administration de la marine française* of Lambert de Sainte Croix (1892); and the excellent little book of M. Loir on *La Marine royale, 1789* (n.d.), may be consulted with pleasure and profit. The three books of A. Jal, *Archéologie navale* (1840), *Glossaire nautique* (1848) and *Abraham du Quesne et la marine de son temps* (1872) are all of high value. *Les Batailles navales de la France* of O. Troude (1867), is a carefully written account of naval actions.

The Histoire de la marine française, pendant la guerre de l'indépendance américaine (1877); *Sous la première république* (1886); *Sous le consulat et l'empire* (1886); *De 1815 à 1870* (1900); and *La Marine française et la marine allemande, 1870-1871* (1873) of E. Chevalier, are thorough and critical. G. Lacour-Gayet, Professor at L'École supérieure de la Marine, has published two books of serious research, *La Marine militaire de la France sous le règne de Louis XV.* (1902), and *La Marine militaire de la France sous le règne de Louis XVI.* (1905). *Les Recherches sur l'ancien clos des galères de Rouen* (1864) of C. de Robillard de Beurepaire, and the life of *Jean de Vienne* by the Marquis Terrier de Loray (1878), are valuable monographs on passages of early French naval history. The *Projets et tentatives de débarquement aux îles britanniques* by E. Desbrière (1900 seq.) is a most valuable authority. A very scholarly *Histoire de la marine française* was begun in 1899 by M. C. de la Roncière.

Miscellaneous:—The standard authorities for Spanish naval history are, *La Marina de Castilla* (1892), and *La Armada Española desde la unión de Castilla y Aragón* (1895-1901), of C. Fernandez Duro. J. C. de Jonghe, *Geschiedenis van het Nederlandsche Zeewezen* (1858), is an admirable and exhaustive history of the Dutch navy. *The History of the Maritime Wars of the Turks*, by Haji Khalfa (or Hugi Chalifa), tr. J. Mitchell for the Oriental Translation Fund (1831), may be read with curiosity and some profit. There are two general histories of the navy of the United States by Fenimore Cooper (1839), and by E. S. Maclay (1894); the second is the fuller, and the more critical. The monographs by Admiral Jurien de la Gravière, covering the whole field of naval warfare from the Peloponnesian War to his own time, contain much information and sound criticism.

NAVY DEPARTMENT: see GOVERNMENT DEPARTMENTS.

NAWABGANJ, the name of three towns of British India.

- (1) The most important is the headquarters of Bara Banki district in the United Provinces, 17 m. E. of Lucknow; pop. (1921) 12,369. It has a considerable trade in sugar and cotton goods. It was the scene of a victory by Sir Hope Grant during the Mutiny.
- (2) A town in Malda district of Bengal, on the Mahananda near its junction with the Ganges, a centre of river trade; pop. (1921) 12,833.
- (3) A town in Gonda district, United Provinces, pop. (1921) 5,305.

NAWANAGAR or **JAMNAGAR**, a native State of India, in the Western India States Agency, Bombay, situated on the south of the Gulf of Cutch. Area, 3,791 sq.m. Pop. (1921) 345,353. Tribute, £7,000, to the British Government, the Gaekwar of Baroda and the Nawab of Junagarh. The chief, whose title is Jam, is a Jareja Rajput of the same clan as the rao of Cutch. Prince Ranjitsinji (b. 1872), well known in England as a cricketer, came to the throne in 1907. There is a State railway from Rajkot to Tamnagar town. Grain, cotton and oilseeds are exported. Marble and copper are found, and there is a pearl fishery in the Gulf of Cutch. The town of Jamnagar is about 5 m. from the seaport of Bedi. Pop. (1921) 42,495. Founded by Jam Rawal in 1540, it is built of stone, has manufactures of silk and gold embroidery and locomotive works and is well-known for its dyeing. Its water is supplied from a reservoir covering 600 acres and an aqueduct 8 m. long.

NAXOS, the largest of the Cyclades (about 22 m. by 16 m.), east of Paros, with which, and adjacent smaller islands, it forms an *eparchia*. In early times it was also called Dia or Strongyle. Rich in vines and famous for its wine, it was a centre of the worship of Bacchus. The god found Ariadne asleep on its shore, when she was deserted by Theseus. The sculptors of Naxos were important in early Greek art; unfinished statues are still to be seen in the quarries, notably the colossal one in Apollona Bay, to the N.E. During the 6th century B.C. a tyrant Lygdamis ruled Naxos in alliance with Peisistratus of Athens. In 501 a Persian fleet attacked it unsuccessfully, but in 490 it was captured and treated with severity. Four Naxian ships joined the expedition of Xerxes, but deserted to the Greek side at Salamis in 480. Naxos was a member of the Delian League (q.v.); but, revolting in 471, was captured by Athens, and remained in her possession till her fall. In later times after its capture, in A.D. 1207, by the Venetian, Marco Sanudo, the duchy of Naxos flourished till the Turks took the island in 1566. Since the War of Independence it has belonged to the Greek kingdom. The ancient remains of a temple (*Palati*), supposed to be that of Dionysus, are on an island just off the town. Naxos is rich in fruit trees, and exports corn, wine and oil, but its most important product is emery. The population is about 17,000.

NAXOS, the earliest Greek colony in Sicily, was founded by Theocles from Chalcis in 735 B.C., on the east coast, south of Tauromenium (mod. Taormina), just north of the mouth of the river Alcantara, where the castle of Schiso now stands. As there were already Sicels at Tauromenium, they cannot have offered any opposition. The adoption of the name of Naxos, the island in the Aegean Sea, may show that there were Naxians among its founders. It soon founded Leontini and Catana. Naxos was the warmest ally of Athens in the Sicilian expedition. In 403 B.C. it was destroyed by Dionysius and its territory given to the Sicels. Its exiles at last found refuge in 358 at Tauromenium. Scanty traces of its walls are to be seen.

NAYAR (**NAIR**), the dominant lay caste in Malabar, on the west coast of southern India. The Nairs were originally a militia, the name being a form of Sanskr. *nāyaka*, "leader," as is Tamil *nāyadu*, *naidu*; but many Nairs now enter civil professions. The caste is split up into numerous groups of varying status, but all are or were curiously submissive to the Nambūtiri Brahmans. To the Nair, as a soldier or marine, marriage was forbidden, and a Nair woman was therefore ritually married to anyone, even a stranger, merely as a form. After that she could be united to a Nambūtiri or a Nair, not below her in group-status, by the *sambandham* ceremony. It would seem that once she was permitted to have several such "husbands," not necessarily brothers, at a time. But, strictly speaking, polyandry did not exist, and it is now probably as extinct in fact as in theory. The *sambandham* became monogamous and usually permanent. From the custom, however, descent in the female line naturally ensued, and it involved also inheritance in that line, a man's heir-at-law being his (uterine) sister's son. But a woman's property was managed by the senior male of her own kin. To remedy the evils of this system the Malabar Marriage Act of 1896 enabled *sambandhams* to be registered as binding and permanent marriages, but little advantage has been taken of the statute, as it merely legalised the prevailing custom.

E. Thurston, *Castes and Tribes of Southern India*, vol. v. (1905), is exhaustive; Moore, *Malabar Law and Custom* (1905).

NAYARIT, a State of Mexico, until 1917 the territory of Tepic, facing on the Pacific ocean and bounded N., E. and S. by Sinaloa, Durango and Jalisco. Area 10,445 sq. miles. Pop. (1900) 150,098; (1910) 171,173; (1921) 162,499. The active volcano of Ceboruco rises in the western part of the territory. The slopes and valleys are densely wooded, the lower regions being very fertile and adapted to tropical agriculture. The rainfall is abundant, and the climate hot, damp and malarial. The Rio Grande de Lerma, or Santiago, is the principal river, whose sources are to be found on the high plateau in the State of Mexico. The next largest river is the Mezquital, which has its sources in the State of Durango, not far from the city of the same name. Among the products of the coast lands are sugar, cotton, beans, tobacco, maize, palm oil, coffee, fine woods and medicinal plants. Mining attracts much attention in the sierras, and its mineral deposits are rich. There are cotton and cigarette factories at the city of Tepic, besides sugar works and distilleries on the plantations. The capital of the State is Tepic. Pop. (1910) 16,778, in 1921, 13,766; attractively situated on a small plateau 3,000 ft. above sea-level, 26 m. E. by S. of its port, San Blas, with which it is not yet connected by rail. The city now is reached by the Southern Pacific of Mexico railway running between Nogales and Guadalajara.

NAYLER or **NAYLOR, JAMES** (1618-1660), English Puritan, was born at Andersloe or Ardsley, in Yorkshire, in 1618. In 1642 he joined the parliamentary army, and served as quartermaster in John Lambert's horse. In 1651 he became a Quaker. He gradually arrived at the conviction that he was a new incarnation of Christ. He gathered round him a small band of disciples, who followed him from place to place. At Appleby in 1653 and again at Exeter in 1655 he suffered terms of imprisonment. In Oct. 1655, in imitation of Christ's procession into Jerusalem, he entered Bristol on horseback riding single—"a rawboned rude figure, with lank hair reaching below his cheeks"—attended by seven followers, some on horseback, some on foot, he in silence and they singing "Hosanna! Holy, holy! Lord God

of Sabaoth!" At the High Cross he and his followers were arrested. His trial occupied the second parliament of Cromwell for several days, and on Dec. 16, 1656, he was convicted of blasphemy and sentenced to be whipped from the Palace Yard to the Old Exchange, to be branded in the forehead with "B" (for blasphemer), to have his tongue bored with a red-hot iron, to be whipped through the streets of Bristol, and to suffer imprisonment with hard labour for two years. On his release he was readmitted into the communion of the Quakers, and spent some time in Westmorland with George Whitehead (1636?–1723).

A collected edition of the *Tracts* of Nayler appeared in 1716. See *A Relation of the Life, Conversion, Examination, Confession, and Sentence of James Nayler* (1657); a *Memoir of the Life, Ministry, Trial, and Sufferings of James Nayler* (1719); and a *Refutation of some of the more Modern Misrepresentations of the Society of Friends commonly called Quakers, with a Life of James Nayler*, by Joseph Gurney Bevan (1800).

NAZARENES, an obscure Jewish-Christian sect, existing at the time of Epiphanius (fl. A.D. 370) in Coele-Syria, Decapolis, (Pella) and Basanitis (Cocabe). According to him (*Panarion*, xxix. 7) they dated their settlement in Pella from the time of the flight of the Jewish Christians from Jerusalem, immediately before the siege in A.D. 70; he characterizes them as neither more nor less than Jews pure and simple, but adds that they recognized the new covenant as well as the old, and believed in the resurrection, and in the one God and His Son Jesus Christ. Recent investigation leads to the conclusion that the Nazarenes of the 4th century are, in spite of Epiphanius's distinction, to be identified with the Ebionites (*q.v.*).

NAZARETH, a town of Lower Galilee, on the northern border of the plain of Esdraelon, 1,600 ft. above sea-level. The population in 1923 was 7,424 (2,486 Muslims, 4,885 Christians). There are numerous places of worship and charitable institutions in the town. The industries are lace-knitting, and the manufacture of mementoes for sale to tourists.

Nazareth is not mentioned in the Old Testament. It first became known as the place where Jesus spent his youth. The village was the home of Joseph and Mary, and to it they returned after the flight to Egypt. In its synagogue Jesus preached the sermon that led to his rejection by his fellow-townsmen. A mass of legends and precarious identifications has grown up with the ages. A sample of the soil in which they took root and flourished may be here given. Antoninus Martyr, who visited Palestine in A.D. 570, tells us: "In the synagogue there is still the book from which our Lord was set to learn A.B.C. In the synagogue, too, is the bench upon which our Lord sat with the other children. This bench can be moved and lifted up by Christians; but Jews cannot at all stir it, nor does it permit itself to be carried out of doors." To-day visitors are shown the church of the Annunciation, the workshop of Joseph, St. Mary's well, Christ's table, the place of precipitation, etc. Only for the well can authenticity be assured.

The Crusaders captured Nazareth in 1100 and transferred there the bishopric of Scythopolis (Beisân). It was taken by Saladin (1187) and re-taken by Frederick II. (1229). On its capture by Beibars (1263), the Christian inhabitants were massacred. In 1517 it came into the possession of the Turks. In the final phase of the World War operations in Palestine, Nazareth was the headquarters of the commander-in-chief of the Turco-German army. It was surprised and captured by a brigade of British cavalry on Sept. 20, 1918. (E. Ro.)

NAZARETH, a borough of Northampton county, Pennsylvania, U.S.A., 7 m. N.W. of Easton; served by the Lackawanna and the Lehigh and New England railways. Pop. (1920) 4,288 (92% native white). It has cement works and a variety of factories. Nazareth was founded by the Moravians in 1740 and was incorporated as a borough in 1858.

NAZARITE or, better, **NAZIRITE**, the name given by the Hebrews to a peculiar kind of devotee. The characteristic marks of a Nazarite were unshorn locks and abstinence from wine (Judges xiii. 5; 1 Sam. i. 11; Amos ii. 11 *seq.*); but full regulations for the legal observance of the Nazarite vow are given in Num. vi., where every product of the grape-vine is forbidden, and the Nazarite is enjoined not to approach a dead body. The law

contemplates the assumption of the vow for a limited period only, and gives particular details as to the atoning ceremonies at the sanctuary by which the vow must be recommenced if broken by accidental defilement. On the expiry of his vow the Nazarite cuts off his hair and burns it on the altar, thus returning to ordinary life. In the earliest historical case, that of Samson, and in the similar case of Samuel (who, however, is not called a Nazarite), the head remains unshorn throughout life, and in these times the ceremonial observances as to uncleanness must have been less precise: e.g., Samson touches the carcass of a lion and is often in contact with the slain.

In the cases of Samuel and Samson the unshorn locks are a mark of consecration to God (Judges xiii. 5) for a particular service. Since, moreover, the Hebrew root *n-z-r* is only dialectically different from *n-d-r*, "to vow," both corresponding to the same original Semitic root (Arab. *n-dh-r*), it would seem that the peculiar marks of the Nazarite are primarily no more than the usual sign that a man is under a vow of some kind. To leave the locks unshorn during an arduous undertaking in which the divine aid was specially implored, and to consecrate the hair after success, was a practice among various ancient nations. The spirit of warlike patriotism that characterized the old religion of Israel could scarcely fail to encourage such vows (*cf.* 2 Sam. xi. 11), and from the allusion in Amos we are led to suppose that at one time the Nazarites had an importance parallel to that of the prophets.

NDEBELE or **MATABELE**, also called Abaka-Zulu. This important member of the Eastern or Zulu-Xosa group, carried large oval shields, and short hand-bladed stabbing assegais, with which they charged at close quarters. They overran the areas occupied by Bushmen (*q.v.*), and conducted successful wars during the earlier part of the 19th century against Barolong, Bastaards and Koranas under the leadership of Moselekatzé. Their herds of cattle were of great size and were carefully tended. They devastated the lands of the Bangwa, Ketse and Bakubia, and have given their name to Matabeleland. See RHODESIA and SOUTH AFRICA: *Ethnology*.

See G. W. Stow, *Native Races of South Africa* (1895).

NEAGH, LOUGH, the largest lake (Irish, "lough") in the British isles, situated in the north-east of Ireland, in the province of Ulster, its waters being divided between counties Antrim (north and east), Down (south-east), Armagh (south), Tyrone and Londonderry (west). Its shape is an irregular oblong, its extreme measurements being 18 m. from north-east to south-west, 16 from north to south, and 11 from east to west. Its circumference, without including minor indentations, is about 64 m., and its area 98,255 ac. or about 153 sq. miles. The shores are generally flat and marshy, or very gently sloping, but flat-topped hills rise near the northern shore, where the lake reaches its extreme depth of 102 feet. The mean height above sea-level is 48 feet. The river Bann, flowing northward, is the only outlet. The principal feeders are the Main on the north, the Crumlin (whose waters have petrifying powers) on the east, the Bann and Blackwater on the south, and the Ballinderry and Moyola on the west. Antrim and Toome, at the north-east and north-west respectively, are the only towns immediately on the shores. The islands are few and near the shores; namely, Skady Tower on the north, Ram's island (with a ruined round tower) on the east, Ready and Coney islands on the south-west. The lough abounds in fish, including gillaroo trout, char and pullen or fresh-water herring. There is a tradition that the lough rose suddenly from a fountain, inundating a populous district, and that remains of buildings may be seen in it.

NEALE, EDWARD VANSITTART (1810–1892), English co-operator and Christian Socialist, was born at Bath on April 2, 1810, the son of a Buckinghamshire clergyman. He studied at Oriel college, Oxford, was called to the bar at Lincoln's Inn in 1837, became a member of the Christian Socialists in 1850 and also joined the council of the Society for Promoting Working

Men's Associations. He founded the first co-operative store in London, and advanced the capital for two builders' associations, both of which failed. In 1851, though strongly opposed by other members of the promoting "Council," he started on his own initiative the Central Co-operative Agency, similar in many respects to the Co-operative Wholesale Society of a later day. The failure of this scheme, together with that of the operatives' cause in the engineering lock-out of 1852 is said to have cost him £40,000. He was closely associated with the movement which resulted in the Industrial and Provident Societies Act of 1876, and the passing of the Consolidation Act of 1862 was almost entirely due to his efforts. Besides publishing pamphlets on co-operation he served on the executive committee which afterwards developed into the Central Co-operative Board, and took an active part in the formation of the North of England Co-operative Wholesale Society in 1863. One of the founders of the Cobden mills in 1866, and the Agricultural and Horticultural Association in 1867, he also promoted the annual co-operative congress, afterwards becoming general secretary of the central board. He was also a director of the Co-operative Insurance Company and a member of the Co-operative Newspaper Society for many years. He visited America in 1875 with a deputation whose object was to open up a direct trade between the farmers of the western States and the English co-operative stores. He died on Sept. 16, 1892.

NEALE, JOHN MASON (1818–1866), English divine and scholar, was born in London on Jan. 24, 1818, and was educated at Trinity college, Cambridge. He occupies a high place as a hymnologist, but principally as a translator of ancient and mediaeval hymns, the best known being probably "Brief life is here our portion," "To thee, O dear, dear country," and "Jerusalem, the golden," which are included in the poem of Bernard of Cluny, *De Contemptu Mundi*, translated by him in full. He also published *An Introduction to the History of the Holy Eastern Church* (1850, 2 vols.); and other works. His *Collected Hymns* were published in 1914.

See *Letters of John Mason Neale* (1910), selected and edited by his daughter Mrs. C. Towle, who in addition wrote a *Life* (1907) of her father.

NEANDER, JOHANN AUGUST WILHELM (1789–1850), German theologian and Church historian, was born at Göttingen on Jan. 17, 1789, of poor Jewish parents named Mendel. He graecized his name into Neander on his baptism in 1806. Educated under Schleiermacher, he became professor at Heidelberg in 1812 and removed to Berlin in 1813. His great learning, his wide sympathies, and a very lovable personality attracted many students, and he did perhaps more than any other teacher to bring a new and less formal spirit into Lutheran teaching. He died on July 14, 1850.

Among the English versions of his works may be mentioned *General History of the Christian Religion and Church*, trans. by J. Torrey (1850–58); *History of the Planting and Training of the Church by the Apostle*, by J. E. Ryland (1851); *Julian and his Generation*, by G. V. Cox (1850); *Life of Jesus*, by J. M'Clintock and C. E. Blumenthal (1848), and *Memorials of Christian Life in the Early and Middle Ages*, by J. E. Ryland (1852).

See A. Harnack, *Rede auf August Neander* (1889), reprinted in vol. i. of Harnack's *Reden und Aufsätze*; A. F. J. Wiegand, *Neanders Leben* (1889); L. T. Schulze, *August Neander* (1890); and K. T. Schneider, *August Neander* (1894). Cf. Herzog-Hauck, *Realencyklopädie*; and P. Schaff, *Germany: its Universities and Theology* (1857).

NEANDERTHAL MAN. The cave in which the Neanderthal bones were discovered, in 1857, is situated in the valley of the Düssel, a tributary of the Rhine. The fragments then found, the vault of the skull, right and left thigh bones, and portions of the shoulder blade, pelvis and ribs, belonged to a separate species—which is represented by remains found in Jersey, in France, Belgium, Spain (Gibraltar), Czechoslovakia and Palestine. The normal skull of this race was long, wide, and, though low, was capacious. The flattening affected the back part of the skull, so that the head must have appeared as set on a thick bull neck. The brow ridges were massive. The chin was lacking. The teeth and palate were specialized in form and point to a rough vegetable diet. The thigh bones are more simian in character than

those of modern man. In sum, the differences between Neanderthal man and modern man are greater than between modern races.

See Sir A. Keith, *The Antiquity of Man*, 2nd ed. (1925); *Journal of the Royal Anthropological Institute* (1928), vol. lviii., pt. 1.

NEAP, a word only used of tides in which the high-water mark is at its lowest, as opposed to "spring tides" (see *TIDE*). The word is obscure in origin; it may possibly be connected with "nip," in the sense of "pinched," "scanty."

NEARCHUS, one of the officers in the army of Alexander the Great. A native of Crete, he settled at Amphipolis in Macedonia. In 325, when Alexander descended the Indus to the sea, he ordered Nearchus to conduct the fleet to the head of the Persian Gulf. Nearchus was then entrusted with the more difficult task of circumnavigating Arabia from the mouth of the Euphrates to the Isthmus of Suez, a project cut short by the death of the king (323). In the troubles that followed Nearchus attached himself to Antigonus, under whom he held the government of his old provinces of Lycia and Pamphylia, and probably therefore shared in the downfall (301) of that monarch.

He wrote a detailed narrative of his expedition, of which a full abstract was embodied by Arrian in his *Indica*.

The text, with copious geographical notes, is published in C. Müller's *Geographi Graeci Minores*, i. (1856); on the topography see W. Tomaschek, "Topographische Erläuterung der Küstenfahrt Nearchs vom Indus bis zum Euphrat" in *Sitzungsberichte der K. K. Acad. der Wissenschaften*, cxxi. (Vienna, 1890). See also E. H. Bunbury, *Ancient Geography*, i. ch. 13; and ALEXANDER THE GREAT. Ancient authorities.—Arrian, *Anab.*, vi. 10, 21; vii. 4, 19, 20, 25; Plutarch, *Alexander*, 10, 68, 75; Strabo, xv. pp. 721, 725; Diod. Sic., xvii. 104; Justin, xiii. 4.

NEATH (Welsh, *Castell-Nêdd*), a municipal borough and market-town of Glamorganshire, South Wales, situated near the mouth of the Neath or Nêdd, on the G.W.R., $7\frac{1}{2}$ m. E.N.E. of Swansea. Pop. (1921) 18,928.

The town perhaps occupies the site of the Roman Nidum on the Julia Maritima from which a vicinal road branched off here for Brecon. At the Norman conquest of Glamorgan, Fitzhamon gave the district between the Neath and the Tawe to Richard de Granaville, who built on the west banks of the Neath first a castle and then in 1129 a Cistercian abbey, to whose monks he later gave all his possessions in the district. All traces of this castle have disappeared. Another castle, built in the same century, on the east bank, was held direct by the lords of Glamorgan, as the westernmost outpost of their lordship. It was frequently attacked by the Welsh, notably in 1231 when it was taken, and the town demolished by Llewelyn ab Iorwerth. The portcullis gate and a tower are all that remain of it; of the abbey there still exist the external walls, with parts of the chapel, vaulted chapter-house, refectory and abbot's house. Neath is a borough by prescription and received its first charter in the 12th century from William, earl of Gloucester, who granted its burgesses the same customs as those of Cardiff. Other charters were granted to it by successive lords of Glamorgan in 1290, 1340, 1359, 1397, 1421 and 1423. By the first of these (1290) the town was granted a fair on St. Margaret's Day (July 20) and as the abbey had extensive sheep walks the trade in wool was considerable. In 1685 James II. granted a further charter. At the Dissolution the abbey and the manor of Cadoxton (part of its possessions) were sold to Sir Richard Williams or Cromwell. Copper smelting has been carried on in or near the town since 1584 when the Mines Royal Society set up works at Neath Abbey; the industry attained huge proportions a century later under Sir Humphrey Mackworth, who from 1695 carried on copper and lead smelting at Melincrythan. With the development of the South Wales coalfield Neath continued its metallurgical associations and concentrated on the by-product industries, thus locally diminishing to some extent the marked depression that has characterized this coalfield since the collapse of the post-war boom in 1921–22. Besides the copper works the town possesses tinplate, steel and galvanized sheet works, foundries and engineering works. In the neighbourhood there are numerous collieries. The Neath Canal, from the upper part of the Vale of Neath to Briton Ferry (13 m.), passes through the town, which is also connected with Swansea by another canal.

One time independent railway lines now form important branches of the G.W.R. to the Rhondda, Aberdare and Brecon respectively.

NEBO or **NABU** ("the proclaimer"), the Accadian translation of various Sumerian ideograms for the god of wisdom and writing, the main seat of whose worship was at Borsippa—south-west of Babylon. It is due to the close association of Borsippa with Babylon after the period when Babylon became the centre of the Babylonian empire that the cult of Nebo retained a prominence only some degrees less than that of Marduk. The amicable relationship between the two was expressed by making Nebo the son of Marduk. In this case the expression of the relationship in this form was intended to symbolize the superiority of Marduk, different, therefore, from the view involved in making Marduk the son of Ea (*q.v.*), which meant that the prerogatives of Ea were transferred to Marduk by the priests of Babylon.

Nebo was the "god of wisdom" to whom more particularly the introduction of writing was ascribed. He takes his place, therefore, by the side of Ea as a cultural deity. The wisdom associated with him had largely to do with the interpretation of the movements in the heavens, and the priests of Nebo at an early age must have acquired widespread fame as astrologers. Assuming now, for which there is a reasonable amount of confirmatory evidence, that the priestly school of Nebo had acquired a commanding position before Babylon rose to political importance we can understand why the worshippers of Marduk persisted in paying homage to Nebo, and found a means of doing so without lowering the dignity and standing of their own god. If Assur-bani-pal, the king of Assyria (668-626 B.C.), in the subscripts to the copies of Babylonian literary tablets invokes as he invariably does Nebo and his consort Tashmit as the gods of writing to whom all wisdom is traced, it is fair to assume that in so doing he was following ancient tradition and that the priests of Marduk likewise were dependent upon the school at Borsippa for their knowledge and wisdom.

The temple school at Borsippa continued to flourish until the end of the neo-Babylonian empire, and school texts of various contents, dated in the reigns of Artaxerxes, Cambyses and Darius, furnish the evidence that the school survived even the conquest of Babylonia by Cyrus. (538 B.C.). Originally this Sumerian deity seems to have been connected with Dilmun and was often identified with the philosophic principle *mummu*; creative word, form. As such he is the son of the water God Enki (Ea), god of the first principle "water." As the god of writing, Nebo has charge of the tables of fate on which he inscribes the names of men and decides what their lot is to be. If in the systematized religious system, Marduk appears as the arbiter of human fates, the conclusion is warranted that Marduk is here imbued with the authority which originally was in the hands of his son. A reconciliation between the rival claims was effected by continuing Nebo in the rôle of scribe, but as writing at the dictation of the gods, thus recording what the divine assembly, gathered in the "chamber of fates" (known as *ubshukinna*) within the precincts of E-Saggila—Marduk's temple at Babylon—under the presidency of Marduk, had decided.

Nebo also does homage to his father by paying him an annual visit during the New Year celebration, when the god was solemnly carried across to Babylon, and in return Marduk accompanied his son part way back to his shrine at Borsippa. Within E-Saggila, Nebo had a sanctuary known, as was his chief temple at Borsippa, as E-Zida, "the legitimate (or 'firm') house." The kings, and more particularly those of the neo-Babylonian dynasty, devote themselves assiduously to the worship and embellishment of both E-Saggila and E-Zida. In their inscriptions Marduk and Nebo are invoked together and the names of the two temples constantly placed side by side. The symbols of the two gods are similarly combined. On boundary stones and cylinders, when Marduk's symbol—the lance—is depicted, Nebo's symbol—the stylus—is generally found adjacent. In astronomy he was identified with the planet Mercury, and with the principal star of Taurus, Aldebaran. In the official reports of astrologers and in official letters, Nebo is even mentioned before Marduk without fear of thereby offending the pride of the priests of Marduk.

His consort, known as Tashmit, plays no independent part, and is rarely invoked except in connection with Nebo.

See also **BABYLON**, **BORSIPPA**, **BABYLONIAN** AND **ASSYRIAN RELIGION**.

BIBLIOGRAPHY.—J. Pinckert, *Hymnen und Gebete an Nebo* (Leipzig, 1920), which gives references to earlier monographs on Nebo. He is often mentioned in the Old Testament, for which see H. Zimmern, in E. Schrader, *Die Keilschriften und das Alte Testament* (3rd ed. H. Zimmern and H. Winckler, 1903). For prayers, see R. Brünnow (vol. iv., 1889) and A. Ungnad (vol. xxii., 1909) in the *Zeitschrift für Assyriologie* (Strassburg); S. A. Strong, in *Proceedings of the Society of Biblical Archaeology* (1898); S. Langdon, *Babylonian Liturgies* (Paris, 1913) and *Oxford Editions of Cuneiform Texts* (Paris, 1927). On Nebo's relation to the metaphysical concept *mummu*, see S. Langdon, "The Babylonian Conception of the Logos," *Journal of the Royal Asiatic Society* (1918, pt. II.). (S. L.)

NEBRASKA, styled "The Tree Planters' State" by act of legislature on April 4, 1895, is near the centre of the United States of America, lying approximately between 40° and 43° N. lat. and between 95° and 104° long. W. from Greenwich. It is bounded on the north by South Dakota, on the east by Iowa and a corner of Missouri, on the south by Kansas, on the south and west by a corner of Colorado and on the west by Wyoming. The Missouri river flows along the eastern and north-eastern border. The extreme length of the State is about 430 m. and the extreme breadth about 210 m. The area is 77,520 sq.m., of which 712 are water surface. Nebraska was named "Tree Planters' State" because Arbor Day originated there and forestry has been given great emphasis by its early pioneers and their successors.

Physical Features.—The main feature of Nebraska topography is a great undulating plain, sloping gradually from the north-west to the south-east, at an average of 10 ft. per mile. This plain is broken along its northern and eastern borders by hilly regions of varied character. The highest point, 5,350 ft. is in Banner county. The point of lowest elevation is 825 ft. in Richardson county, at the south-eastern corner. The mean elevation is about 2,500 ft. The United States and State topographical surveys classify Nebraska into four regions: the loess, the sand-hills, the high plains and what hitherto has been called the Bad Lands, but is now named the Pierre Shale hills or Gumbo plains.

The loess region includes about 43,000 sq.m. of the best farming region in the eastern, central and southern parts of the State. In the loess plains the landscapes flow in a series of long gentle waves toward the south-east. Along the Missouri, the Republican, and at some points elsewhere, the waves converge into moderate hills. The sand-hill region lies west and north-west of the loess plains, like an open fan with the handle toward the north-east. The main region includes about 18,000 sq.m. with outlying areas dotting

MAP SHOWING THE MAIN ROADS IN NEBRASKA

other parts of the State. Scattered through the sand-hills are rich valleys, lakes and fertile table-lands. The sand-hills themselves are for the most part, a series of sloping hills, rising sometimes into pinnacles, at other times stretching in gentle plains. Their present contours are chiefly the result of wind action. Save in rare instances they have long ceased to be shifting dunes; for, with the cessation of prairie fires and the increase of settlement, they have become well grassed over and stable. Their general height is from 25 to 100 ft. above the valleys between.

West and north-west of the sand-hills lie the high plains, mostly

level stretches of table-land, broken occasionally by deep canyons. In this region are about 12,000 sq. miles. Included in this region are two areas of evergreen wooded mountains, the Wild Cat range, in Scotts Bluff and Banner counties and the Pine Ridge in Sheridan, Dawes and Sioux counties. A conspicuous feature of these high plains is the buttes, isolated rugged hills, nearly destitute of vegetation, rising hundreds of feet above the surrounding plain. The entire plain-region rises to an average height of from 3,000 to 4,000 ft. with large areas of level rich soil. The North Platte river, with its valley, 10 to 12 m. in width, cuts through the heart of the high plains and is joined near the edge of the sand-hills by the South Platte river entering from Colorado. The Pierre Shale region (or Bad Lands) occupies an area of about 1,000 sq.m. chiefly in Sioux county, with minor sections in Dawes and Sheridan counties. Their weathered slopes and valleys furnish fine grazing and, with water, grow abundant crops. In connection with the Pine Ridge and Wild Cat mountains this section furnishes a region of rare scenic beauty and a sheltered range for stocks.

Rivers and Drainage Basins.—All the drainage of the State reaches the Missouri river, which skirts the eastern border for approximately 450 miles. Present navigation is limited to ferry and excursion boats. Chief tributaries of the Missouri in Nebraska are the Platte, with its branches; the Niobrara; the Republican; the Big and Little Blue; the Big and Little Nemaha. The Platte river is the dominant and characteristic Nebraska river. Its wide terraced valley, extending across the entire State and leading to mountain passes, has made it the chief highway across the continent from the beginning. Its channel varies from $\frac{1}{2}$ m. to 1 m. in width, and is filled with islands of varying size and shape. Its waters are shallow with a fall of about 6 to 8 ft. per mile. In the spring its depth varies from 1 to 6 feet. In the late summer use of water for irrigation leaves its middle course in the State entirely dry. The Loup and Elkhorn rivers, principal tributaries of the Platte, head in the sand-hills and are nearly 200 m. long each, with an abundant flow of water through beautiful valleys. Of Nebraska's 77,000 sq.m. about 40,000 are in the drainage basin of the Platte and its tributaries. The Niobrara is a very swift stream over 400 m. in length, running for about half that distance through canyons and hills wooded with pine and cedar. Beautiful waterfalls exist upon the Loup, Niobrara and their tributaries, some of them 70 ft. in height, and the entire region, with its hundreds of lakes scattered over the sand-hills, makes an attractive tourist camping ground. The Republican river is the principal stream along the southern border, as the Niobrara is in the north. The Big Blue and the Little Blue, about 200 m. in length, with their tributaries, drain the south-central part of the State. Their flow is more sluggish, the grade gently sloping back to the surrounding prairie. The Big and Little Nemaha, about 150 m. long, drain the south-east section.

The lake region in Nebraska is chiefly in the sand-hills, on the headwaters of the Elkhorn and Loup, making an area about 200 m. long by 50 m. wide. Several hundred lakes in this district furnish ideal fishing and hunting grounds. The lakes vary greatly in size and in water, from fresh spring-fed bodies to strongly alkaline. Artesian water exists in at least ten different counties with over 1,500 flowing wells.

Climate.—The climate of Nebraska is inland or continental. The prevailing wind of the year is north-west; but in the spring, summer and much of the autumn, its predominance is greatly reduced by south and south-west winds from the Gulf of Mexico. Wet and dry years run in irregular cycles with no sufficient data to formulate a rule for them. A curve covering the past 70 years would show dry cycles in 1860-63, 1890-95, 1910-13.

The normal mean annual temperature (compiled from records 1876-1927) is 48.7°. There is a considerable difference in the averages for different months, the normal means of January and July through 50 years being 21.9° and 74.6°. The actual growing season between frosts varies from 165 days in the south-east to 135 in the north-west. The normal mean annual precipitation for the whole State is about 23.54 in. in rain and melted snow, the actual yearly average varying through 50 years from 13.30 to 35.60 inches.

Soil.—A soil of remarkable fertility is Nebraska's fundamental asset. Silt is the most common and most fertile physical element in the State soils. It is the dominant element in the richest areas and, supplemented by fine sand, forms a combination easily worked by farm implements and responding with quick and sustained growth in the cultivation of the world's staple food crops which are the chief product of Nebraska. The top soils over most of the State are from 1 to 8 ft. in depth, a rich brownish-black vegetable humus. Below this top soil over the largest area is found the loess subsoil, varying from 10 ft. to over 200 ft. in depth. The soil in the sand-hills region is largely very fine sand mixed with silt. It never bakes, it holds moisture and, under favourable treatment, covers itself with vegetation. Fertile valleys and slopes in the sand hills grow exceptional crops. The soils of the high plains and the butte region are chiefly a mingling of silt and fine sand, rich in lime, derived from the decomposing Arickaree strata. These soils produce splendid crops with a minimum of rainfall under modern soil culture methods. The Pierre Shale soils contain elements of great fertility.

Flora.—Grasses are the outstanding feature, 200 species growing within the State, a greater variety of native forage species than any other State. Between 3,000 and 4,000 floral species have been identified within the State, including 64 trees and 77 shrubs growing native. About 1,000,000 ac. out of 49,000,000 are in forest trees.

Government.—A constitution adopted in 1875 forms the basis of the State Government. Eleven amendments were made during the period 1875-1918. A fourth Constitutional convention assembled in 1919 and submitted 41 additional amendments, which were adopted by the voters in 1920, making the Constitution as it exists to-day.

The general election, State and local, is in even-numbered years on the first Tuesday after the first Monday in November, but municipal and school district elections may be held at other times. In 1909 the State enacted a law providing for the non-partisan nomination of all judges, of all superintendents of public instruction and of regents of the State university.

The governor is the chief executive officer of the State, and one of the 11 executive State officers chosen by direct vote of the people. The other ten executive officers are: lieutenant-governor, secretary of State, auditor, treasurer, superintendent of public instruction, attorney-general, commissioner of public lands and buildings and three railway commissioners. All, governor included, are elected for a term of two years, except the superintendent of public instruction, who is elected for four years and the railway commissioners for six years. The governor appoints, with the approval of the senate, secretaries of the code departments, members of the board of control and a few other officers. He fills vacancies in State offices arising from death, resignation or removal. The governor may remove any officer appointed by him for incompetency, neglect of duty or malfeasance. The legislature consists of a senate of 33 members and a house of representatives of 100 members, and meets in regular session at Lincoln on the first Tuesday of January each odd-numbered year. Except at the governor's request, no bill or joint resolution may be introduced at a regular session after its 20th day. Special legislation of various kinds is expressly prohibited, and in the bill of rights it is declared that "all powers not herein delegated, remain with the people."

Administration of justice is vested in a supreme court, 18 district courts, county courts, municipal courts, justices of the peace, police magistrates and certain State administrative officers. The supreme court consists of six associate justices, elected one from each congressional district, and one chief justice elected from the State at large, all being chosen for a six-year term. Each district court consists of from one to nine judges, total number 35, elected for a term of four years. County courts have one judge, elected by the voters of the county. Municipal courts have from one to five judges each, elected by voters in the city. Lincoln and Omaha were the only cities with municipal courts until 1927, when the legislature enacted that cities having a population of 9,000 to 25,000 could, by initiative petition and referendum, create munic-

ipal courts. Police magistrates are elected from the municipality at large, justices of the peace from each rural precinct. Police judges and justices of the peace are the only judges paid by fees, all others receiving salaries. The district court is the court of general, original, legal and equity jurisdiction. It is a court of record, and its jurisdiction is unlimited in amount, and almost unlimited as to subject matter. Its appellate jurisdiction extends to all appeals from inferior courts. The inferior courts—county, municipal, police magistrates and justices of the peace—all have a limited jurisdiction, both in amount and in subject matter. The supreme court is the court of last resort. Under the Constitution, appeal to this court may not be denied in any case.

Voters in each county may choose the district-commissioner system or the township-supervisor system of government. Out of 93 counties, 24 had township supervisor government in 1928. There are about 600 incorporated cities and villages in the State. Under the Constitution and the State law there are three possible forms of city government: The mayor and council plan; the commission plan, which may be adopted only by cities of over 2,000 population; the city-manager plan, which may be adopted by any city, except Omaha, having over 1,000 population. Since 1912 any city with a population of more than 5,000 may frame a home-rule charter. Omaha and Lincoln have adopted the home-rule charter plan of government, freeing themselves to a large extent from the control of the legislature.

Population.—In 1920 the population of the State was 1,296,372, and in 1928 (United States census estimate) 1,408,000. Of the 1920 population, 1,279,219 were white; of these 149,652 were foreign-born, chiefly from Germany (40,969), Sweden (18,821), Czechoslovakia (15,758) and Ireland (5,422). The density of population was 16.9 per sq. m. in 1920. The five cities having, in 1925 (United States census estimate) a population over 10,000 are given in the table below:

	1925	1920	1910	Increase 1910-20 %
Omaha	211,768	191,601	124,096	54.4
Lincoln*	70,000	54,948	43,973	25.0
Grand Island	15,602	13,947	10,320	35.1
Hastings	12,954	11,647	9,338	24.7
North Platte	13,670	10,466	4,793	118.4

*For 1927. Suburbs, University Place and Bethany, annexed in that year.

The shift of population from farms to cities began before 1920. In the decade 1910-20, 33 out of 93 counties showed a decrease in total population, and 43 (chiefly the older counties) showed a decrease in rural population. Indian population of Nebraska at the time of the first white settlement totalled about 30,000. There remain now in Nebraska, of the original tribes, about 3,000. All are now full citizens, holding land in severalty and voting.

Finance and Taxation.—The general property tax, established in the year 1867, was supplemented by a corporation licence tax in 1909, and by other State licences and fees and special taxes, and by contributions from the United States Treasury, to provide for the growing expenses of government. In the biennium (1925-27), out of a total State budget of \$32,000,000, the general property tax supplied about \$14,000,000; fees and licence taxes, \$12,000,000; miscellaneous \$2,000,000; U.S. contributions \$4,000,000. In 1927 the assessed valuation was \$3,141,146,000, upon which the State general property tax was \$11,862,473. The county tax \$11,017,262, the high-school tax \$1,400,036, the school tax \$28,951,782, the city and village tax \$9,061,253, the township tax \$1,622,138, making a total general property tax for all purposes of \$63,914,947. The State has had no bonded debt since 1900. The legislature, in 1909, passed an act establishing a State guaranty fund "for the protection of the depositors in State banks." The act provides for a levy not to exceed $\frac{1}{10}$ of 1% annually on the average deposits of each State bank. This yields a maximum of \$1,500,000 per year which is used for the payment of depositors when a bank fails. There were in 1928 789 State banks, with deposits of approximately \$254,000,000 and capital stock of about \$22,264,000; and about 168 national banks with deposits

of \$202,735,000, and capital stock of \$16,215,000.

Education.—The United States endowment of public education embraced about 3,000,000 ac. of land for common schools, 90,000 ac. for the College of Agriculture and 46,080 ac. for the University of Nebraska. Under the present law enacted in 1897, this land can be leased but not sold. The present endowment of the common schools includes 1,600,000 ac. of land, and \$12,000,000 proceeds of former land sales invested in securities; for the university and agricultural college about 12,000 ac. and \$900,000 invested in securities. In addition the State endowed Peru Normal college with 12,000 ac. of State land. The annual income from these school endowments is about \$1,000,000. The percentage of illiterate population above ten years of age was 1.4% in 1920, a percentage lower than that of any other State except Iowa (1.1%). Since 1891 a Free Text-book law has been in force. In the common school system in 1926 there were 7,653 school-houses with 327,472 enrolment, and 14,571 teachers. The total investment in school property was \$64,000,000 and the annual expenditure \$33,000,000.

There are four State normal teachers colleges, with a total attendance, in 1926, of 4,906 students and 162 faculty members; one at Peru (opened 1867), one at Kearney (1905), one at Wayne (originally private; purchased by the State in 1909) and one in Chadron (established by an act of 1909). The University of Nebraska at Lincoln was established in 1869 by an act of the State legislature and was opened in 1871. Connected with it and governed by the same regents are the College of Agriculture at Curtis and the agricultural experiment stations at North Platte, Valentine and Scottsbluff. The university in 1928 consisted of ten colleges and three schools, as follows: colleges of agriculture, arts and sciences, business administration, dentistry, engineering, graduate, law, medicine (at Omaha), pharmacy and teachers; and schools of fine arts, journalism and nursing. The total enrolment for the school year 1926-27 was 11,848 students and about 400 faculty. Nearly all educational institutions in the State are co-educational. Among the private educational institutions are: Nebraska Wesleyan university, at Lincoln; Union college, at College View, a suburb of Lincoln; York college, at York; Cotner university, at Lincoln; Grand Island college, at Grand Island; Doane college, at Crete; Hastings college, at Hastings; University of Omaha, at Omaha; Dana college, at Blair; Nebraska Central college, at Central City; and Midland college, at Fremont.

The State board of control and the State department of public welfare exercise a general supervision over charitable and penal institutions. The State institutions maintained in 1928 included: Girls' Training school, at Geneva; Industrial school for Boys, at Kearney; Womens' Industrial Home, at Milford; Orthopaedic hospital, at Lincoln; soldiers' and sailors' homes, at Grand Island and Milford. These institutions in 1927 had 6,377 inmates, 917 employees and their cost for the biennium 1925-27 was \$4,713,300, about one-eighth of the State's total expenses.

Agriculture and Live Stock.—Of a total of 49,170,777 ac. there were, in 1925, 17,904,000 ac. in actual cultivation, 3,056,000 ac. in wild hay, and 26,728,000 ac. devoted to range and pasture purposes. The total crop values, exclusive of fruit, were \$371,682,000 in 1927. The total number of farms had increased from 124,411 in 1920 to 127,734 in 1925. Of the total farms in 1925, 70,889 were operated by owners and 56,838, or 44.58%, by tenants. The value of farm-land and buildings was \$2,794,807,717 in 1927 as compared with \$2,712,107,760 in 1920; the average acreage per farm in 1927 was 377, as compared with 339 in 1920 and 297 in 1910. Improved machinery is the chief cause of the increase in larger farms. Production of principal crops for the year 1927 is shown in the following table:

Nebraska Field Crops, 1927

Maize	8,805,000 ac.	291,446,000 bu.
Wheat	3,630,000 "	73,826,000 "
Oats	2,441,000 "	69,814,000 "
Barley	246,000 "	7,577,000 "
Rye	274,000 "	4,110,000 "
Hay	4,783,000 "	7,201,000 tons
Sugar-beets	82,000 "	1,048,000 "

The value of live stock sold in 1927 was about \$281,360,000, including dairy and poultry products. The total value of live stock and its products sold in 1926 was \$344,598,858. The heavy sales of cattle during that year is largely responsible for the greatly increased value of gross sales. Domestic animals on farms in 1927 and 1920 were respectively: horses, 782,000, 961,000; mules, 116,000, 99,847; cattle, 2,875,000, 3,154,265; swine, 4,546,000, 3,435,000; sheep, 995,000, 750,000. The dairy industry has grown from 535,000 head of milch cows in 1920 to 613,000 head in 1927, and the total value of dairy cows in 1927 was \$45,362,000 as against \$36,780,000 in 1926. The number of poultry increased from 11,932,243 in 1920 to 13,517,021 in 1927. In 1926 the total value of poultry and eggs marketed was \$25,587,468. Nebraska ships annually 16,000,000 lb. of dressed poultry, and about 2,000 cars of live poultry.

Irrigation and dry-farming have made remarkable increase in the western part of the State. Improved farming methods and favourable rainfall have brought large acreage and crops of winter-wheat over the entire high plains region. Motorized machines and "combines" which harvest and thresh in one operation have increased. Tractor ploughs which run day and night without an operator are used in the fields. In 1927 there were approximately 500,000 ac. under irrigation. The irrigation projects are mostly in the western or central counties of Scotts Bluff, Morrill, Garden, Keith, Dawson and Lincoln. The Platte is the chief source of water for all the irrigation projects so far developed. The sugar-beet industry in the irrigated regions has developed from 554,646 tons in 1919, to 1,048,000 tons and seven factories in 1928. The total value of the 1927-28 crop was \$8,216,000, as against \$7,274,000 for 1926-27, \$5,823,786 for 1919, and the five-year average is \$6,302,000. Sheep and cattle-feeding accompany the beet sugar industry, over 300,000 head of sheep and 50,000 of cattle being fattened in the North Platte valley in 1927.

Industries and Transport.—Manufacturing has grown, chiefly in the conversion of raw products of agriculture into commodities for market. The United States census of manufactures for 1925, showed 1,306 manufacturing establishments in the State, employing 27,200 wage earners. Nebraska's rank among the States in 1925, according to the amount of raw material manufactured (\$348,397,110), was 23rd; according to total factory output (\$443,308,700), it was twenty-eighth. The chief industries in 1925, ranked according to the value of their products, were: slaughtering and meat packing, \$198,020,335; the manufacture of butter, cheese and evaporated milk, \$38,873,667; flour and grain mills, \$29,155,490; steam railway construction and repairs, \$15,408,651; bakeries, \$12,673,656; printing and publishing, newspapers and periodicals, \$10,823,482.

Metallic minerals are almost absent from the State. The total value of the mineral output in 1925 was \$3,358,585 or .07% of the total production for the United States. The chief products in the order of their importance were cement, sand and gravel, clay products and stone.

Missouri river navigation was a leading method of transportation until the construction of the railways in the '70s. As a result of railway competition it declined to almost nothing. Railway mileage amounted to 6,454 m. in 1926. The principal railway construction since 1920 has been branch railways for transportation of sugar-beets in the North Platte valley. In 1927, all but four counties had railway outlets. Ten trunk railways radiate from Omaha, five of them with a network of feeders over the State. The Union Pacific was the first railway, beginning construction on July 13, 1865, at Omaha. There were in 1928 approximately 206 m. of electric railway operating in the State, chiefly as city street transportation systems. Motor truck transportation has greatly increased.

The most important development in Nebraska in the years 1920-28 has been the great extension of improved highways directed from the State engineer's office. An era of road-building and road maintenance began in 1917 which has been greatly promoted by the rapid increase of motor vehicles. The total mileage in the State highway system on Jan. 1, 1927 was 6,256. Of this total 2,660 m. were gravelled, 104 m. paved and 3,492 graded

roads. The total number of motor vehicles registered in 1927 was 373,917, of which 31,555 were motor trucks and buses. Nebraska is traversed by two great trunk highways, or tourist lines, the Lincoln highway and the Detroit-Lincoln-Denver, each gravelled almost the entire distance across the State. North and south gravelled trunk lines include the Kansas City-Omaha, the Cornhusker highway and the Meridian highway. The Yellowstone Park and Oregon Trail highways traverse the North Platte valley.

History.—Francisco Vásquez Coronado, with 30 Spanish horsemen and two Indian guides, crossed the great plains northeast from the Rio Grande valley in the summer of 1541, seeking the kingdom of Quivira, which they found to be nothing more than Indian villages not far from 40° N. lat. From Coronado's account most historical writers believe that he was the first white man to reach Nebraska and that view has been incorporated into the literature and pageantry of the State. In 1720, a Spanish and Indian command under Col. Pedro de Villasur, marched from Santa Fe to the valley of the Platte for the purpose of conquering and colonizing the Nebraska region. His command was massacred by the Otoe and Pawnee Indian tribes, probably near the present city of Columbus, on Aug. 10. French explorers came up the Missouri river to Nebraska shores in 1700. In 1739-40, the Mallet brothers (French) crossed the region from east to west naming the Platte river in their report. Nebraska was claimed by France, Spain and England. From about 1700 until 1763 France was the leader in trade and exploration. From 1763 until 1803 Spain exercised authority, but the white population and language of the vast Louisiana province, including Nebraska, remained French. Nebraska passed to the United States in 1803 as part of the Louisiana Purchase. American exploration by Lewis and Clark (1804-06); Lieut. Z. M. Pike (1806); Manuel Lisa (1807-20); Major Stephen H. Long (1819-20); Col. Henry Dodge (1835); Lieut. John C. Fremont (1824-44); and Lieut. G. K. Warren (1855-57) made known to the public important facts regarding the region. Major Long's map designated the country as a "great desert," and his report stated that the country was "entirely unfit for agriculture."

Records show the existence of trading posts in 1795, 1802, 1807, 1812, the last two near the present towns of Ft. Calhoun, 16 m. north of Omaha, and Bellevue. Manuel Lisa, of Spanish descent, was the leading fur trader and first white settler (1807). The most important early white settlement was Ft. Atkinson on the present site of Ft. Calhoun, a military post of 1,000 men, and the centre of the first white industry and agriculture (1819-27). Bellevue (1823), was the first permanent white settlement, and in 1849 the first United States post-office in Nebraska. In 1825 the Government acquired the first Indian lands and in 1833 the first white missionaries began work among Nebraska tribes. Ft. Kearny was established in 1847 where Nebraska City now stands, and in 1848 it was relocated on the south bank of the Platte about 6 m. south-east of the present city of Kearney.

The overland trail era was the next important period in Nebraska history. Beginning in 1832 with the Oregon trail which followed the Little Blue and the south bank of the Platte across the State, followed by the Mormon or California trail in 1847 up the north bank of the Platte, and the subsequent Nebraska City cut-off (established 1858-60), Nebraska furnished the principal routes from the Missouri river to the Rocky mountains and Pacific coast. In a single year 50,000 people with nearly as many live stock and 8,000 wagons crossed the region by these highways.

The movement to organize Nebraska Territory arose directly from the conflict between the United States and Great Britain for the possession of the Oregon country. The name "Nebraska" derived from the Otoe name, "Ne-brath-ka," or Shallow Water, for the Platte river, was first suggested by Lieut. Fremont in 1843, recommended by Secretary-of-War Wilkins in 1844 and adopted by Stephen A. Douglas who introduced bills for the organization of the territory in 1844, 1848 and 1852. In 1852-53, a provisional Territorial Government was formed by Wyandot Indians and licenced white residents on Indian lands. A delegate was elected to Congress, but not seated. The final Kansas-Nebraska bill, providing for two territories, became the centre

of an intense struggle in Congress between the North and South, involving the extension of slavery, the removal of Indians and rival routes for the proposed Pacific railway. The bill, signed on May 30, 1854, by President Franklin Pierce, repealed the Missouri Compromise of 1820, provided that the new territories should be slave or free as voted by citizens in each, and reopened the fierce sectional conflict between the North and South. The conflict split the Democratic Party, destroyed the Whig Party, led to the organization of the new Republican Party and to the series of events leading to the Civil War.

Nebraska Territory, as organized in 1854, included the vast region from the 40° N. lat. to British America, and from the Missouri and White Earth rivers to the summit of the Rocky mountains. In 1861 and 1863 it was reduced by the creation of other territories to nearly its present boundaries, the only important change since then being the annexation in 1890 of what is now Boyd county. White settlers in the territorial period (1854-67) were chiefly in a narrow strip along the Missouri river, with isolated ranches westward along the Platte valley and the Oregon trail. The enactment by Congress in 1862 of the Union Pacific Railroad Act and the Free Homestead Act aided white settlement, the first claim under the Free Homestead Act being located in Nebraska, on Jan. 1, 1863. In 1861 there were probably 30,000 inhabitants in the territory and 3,300 men from Nebraska were enlisted for the Union army in the Civil War. The great industry in this period was transport by the overland trail. Rival routes from Kansas City, St. Joseph, Leavenworth, Atchison, Nebraska City and Omaha, converged at Ft. Kearny on the Platte. Freight carried over these trails amounted to 200,000 tons in 1865. Over them ran the overland stage coaches, carrying passengers, and in 1860-61, the famous "Pony Express," whose service ended with the completion of the overland telegraph in the latter year. This trail transportation business terminated in Nebraska with the construction of the Union Pacific railway in 1865-69.

The legislature first met in Omaha on Jan. 16, 1855, and annually thereafter, during the territorial period. Important early legislation related to land claims, bank charters, schools, prohibition and woman suffrage. A fight for the location of the capital between rival towns of the Missouri river front, Bellevue, Brownville, Nebraska City, Plattsmouth, Omaha and Florence resulted in Omaha holding the capital, but in the creation of a violent feud between the North and South Platte sections which continued for many years. An episode of this fight was the "Florence secession" of 1858, when a majority of the legislature deserted Omaha and adjourned their sessions to Florence. In 1858-59 the South Platte region held a convention, sent delegates and sought annexation to Kansas. Great speculation in town sites and lands culminated in 1857 in general distress and in the failure of all territorial banks but one, \$400,000 of bank notes becoming worthless.

Statehood.—A proposition to form a State in 1860 was defeated at the polls. Congress passed an Enabling Act on April 19, 1864, but a convention elected in that year to frame a State Constitution adjourned without action. A Constitution was adopted by the legislature in 1866, submitted to the voters on June 2, 1866 and carried by a majority of 100 in a total vote of 7,766. The Republicans favoured statehood in order to help the Republican majority in Congress in its struggle with President Andrew Johnson; the Democrats opposed it. The Constitution, as adopted, limited suffrage to free white males. Congress refused to admit Nebraska until the territorial legislature passed an act pledging that negroes would not be barred from the ballot. These terms of admission were accepted by Nebraska and carried in spite of President Johnson's veto, and Nebraska was proclaimed a State on March 1, 1867.

The South Platte region had a majority in the first State legislature of 1867 and passed an act providing for the relocation of the capital in that section. Opponents of removal offered an amendment naming the capital "Lincoln," in order to make it distasteful to Democratic members from the South Platte region. The latter accepted the amendment and the capital commission on July 29, 1867, located and named the capital site at the little

hamlet of Lancaster, on Salt creek.

The Democratic Party was the sole political party in Nebraska from 1854 to 1858. The only political divisions were factions of that party. The Republican Party was first organized in the campaign of 1858. Slavery domination of the national administration and especially President Buchanan's veto of the Free Homestead Act changed territorial politics, giving the Republicans control in 1860, which was firmly held by them until 1890. In that year the Farmers' Alliance organized the Peoples' Independent or Populist Party. A three-cornered fight resulted in the Democrats getting the governor, and the Farmers' movement a majority of the legislature. The Populists elected the governor in 1894 and in 1896, by fusion with the Bryan Democrats and Silver Republicans, swept the State. Defalcations disclosed of Republican State officials amounting to over \$700,000 assisted the fusion party in controlling the State until 1900 when the Republicans again came into power. The Populist Party disintegrated and disappeared as a political factor after 1904, and political control has fluctuated between the Democrats and Republicans since then. The legislature in 1919 passed what is called "The Civil Administrative Code Act," consolidating about 25 State administrative organizations into six departments: finance, agriculture, labour, trade and commerce, public works, public welfare. The legislatures from 1919 to 1927 granted \$9,000,000 for the construction of a new State capitol. This building, designed by Bertrand Goodhue, is one of the noted artistic structures in America.

NEBRASKA CITY, a city of south-eastern Nebraska, U.S.A., on the high bank of the Missouri river, 40 m. below Omaha; the county seat of Otoe county. It is on Federal highways 73 and 75, and is served by the Burlington Route and the Missouri Pacific railway systems. The population was 6,279 in 1920 (91% native white) and was estimated locally at 8,000 in 1928. It is the seat of the State Institute for the Blind, and the trading and shipping point for a fine agricultural region. "Arbor Lodge" (formerly the home of J. Sterling Morton, a member of Cleveland's cabinet and the originator of Arbor Day) with its fine arboretum, is now a State park. Nebraska City is one of the oldest settlements in the State, and for some years at the height of the migration westward it was the largest city. A fort was established on the site in 1847, but was abandoned the following year for a location farther west. In 1858 several settlements in the vicinity were consolidated and incorporated as Nebraska City, and it was made the headquarters of a great freighting firm which distributed supplies to the army posts between the Missouri and the Rockies (amounting to 2,782,258 pounds in 7 months in 1859).

NEBUCHADREZZAR or NEBUCHADNEZZAR, king of Babylon, the *Ναβουχοδρεζζαρος* of the Greeks. The first and last are nearer to the original name as it is found on the cuneiform monuments, viz., Nabu-kudurri-ušur, "Nebo, defend the land-

mark." Nebuchadrezzar seems to have been of Chaldean origin. He married Amuhia, daughter of the Median king, according to Abydenus, and in 605 B.C. defeated Necho at Carchemish, driving the Egyptians out of Asia and annexing Syria to the Babylonian empire. In the following year he succeeded his father Nabopolassar on the Babylonian throne, and continued the restoration of Babylon, which he made one of the wonders of the world. His "new palace" there was built in fifteen days; temples were erected to the gods, the great walls of the city were constructed with a moat surrounding them, the Euphrates was lined with brick and a strong fortress erected. Canals were dug throughout the country and a great reservoir excavated near the capital. Only a fragment of his annals has been preserved, recording his campaign against Amasis (Ahmosi) of Egypt in his thirty-seventh year (567 B.C.) when he defeated the soldiers of "Phut of the Ionians." Tyre revolted in the seventh year of his reign, and was besieged for 13 years; a contract-tablet dated in his fortieth year shows that at that time it was under Babylonian officials.

After the investment of Tyre Nebuchadrezzar marched against Jerusalem, put Jehoiakim to death and placed Jehoiachin on the throne. Three months later Jehoiachin was deposed and Zedekiah made king in his place. Zedekiah's revolt in 588 B.C. led to another siege of Jerusalem, which was taken and destroyed in 586 B.C. (See JEWS and JERUSALEM.) From his inscriptions we gather that Nebuchadrezzar was a man of peculiarly religious character.

See Josephus, *Cont. Apion*, i. 19; Eusebius, *Praep. Evangel.* x.

NEBULA, in astronomy, the name given to certain luminous patches in the sky. (Latin for "mist," Greek *νεφέλη*). Dark nebulae are also known. The smaller luminous nebulae resemble distant comets when seen in a telescope of moderate power but can be easily distinguished from them, because the latter, being within the confines of the solar system, appear to move among the stars, while the nebulae, being at stellar distances, have no such motion. They are almost without exception invisible to the unaided eye, and, while a few hundred of them can be seen with a small telescope, it requires the combined aid of a very large instrument and the photographic plate to study these faint objects at all adequately. The two largest and brightest are the spiral nebula in Andromeda and the irregular nebula in Orion.

The nebulae are very numerous, their number being reckoned in hundreds of thousands, but only a comparatively few of these appear large enough to show much structure even on photographs taken with our most powerful telescopes. As the nebulae present to us luminous *surfaces*, as opposed to the point-image of a star, even the largest telescope, though it makes them appear larger, does not make them any brighter than they are to the unaided eye. But the photographic plate has the advantage over the human eye of being able to accumulate the effect of exposure to a faint source of light, and thus by means of long exposures, sometimes extending over many hours, it is possible to photograph nebular detail far too faint to be observed visually in any telescope.

Historical.—Before the days of photography the nebulae were observed by Charles Messier in Paris in 1771; he recorded 103 of them; by Sir William Herschel at Slough, and by Sir John Herschel both there and at the Cape of Good Hope, who raised the number of known nebulae to 4,000; and in the middle of the 19th century by the third Earl of Rosse, with his giant reflecting telescope at Parsonstown. They were first observed with the spectroscope in 1864 by Sir William Huggins, whose discovery that some of them had a gaseous spectrum dispelled the idea then becoming current that all nebulae were aggregations of stars, and that it was merely a matter of obtaining more powerful telescopes to show them as such. The catalogues formed by J. L. E. Dreyer contain about 10,000 nebulae discovered visually. They have not yet been superseded by any general catalogue based upon photographic observations.

Amongst the pioneers of photography as applied to the study of the nebulae were A. A. Common and Isaac Roberts in England, and later E. E. Barnard and J. E. Keeler in America. During the present century the nebulae have been extensively photographed at the Lick, Mount Wilson, and Lowell observatories in America,

at Heidelberg by Max Wolf, and at Helwan in Egypt.

Classification.—The nebulae fall naturally into two groups, which have been called the galactic and the extra-galactic, the former class comprising those nebulae which lie in or near the plane of the Milky Way, and the latter those which are found outside this plane. This is not merely a spatial classification, as the two classes of objects differ fundamentally in their nature, and they will consequently be discussed separately.

THE GALACTIC NEBULAE

These nebulae, which are only found in or near the Milky Way, are of three kinds: (a) *Dark Nebulae*, which do not shine, and can only be detected because they obscure the light coming from the stars that lie behind them; they are irregular in shape; (b) *Diffuse Nebulae*, also irregular in shape; they are often of very intricate structure; (c) *Planetary Nebulae*, which are round, or nearly so, and have sharply defined edges.

Dark Nebulae.—There are in the Milky Way a great number of dark patches, some of them entirely devoid of stars. A few of these were discovered by Sir John Herschel, who thought them to be holes through which we looked into empty space beyond; and Barnard, whose studies of these dark nebulae finally showed that they were caused by the presence of clouds of non-luminous matter, was at first loth to believe they were other than holes or spaces actually containing no stars. They vary in size from small patches only a minute of arc in diameter to the large lanes in Ophiuchus and Scorpius. Even the huge rift, 120° long, which divides the Milky Way from Cygnus to Centaurus, must be considered to be of a similar nature. It stretches right through the region where most of the globular clusters are found, and yet there is not a single one of these clusters within its boundaries.

When stars appear in these dark spaces, it seems likely that in general they lie between us and the obscuring cloud, though there are undoubtedly cases where the stars are actually involved in it. In fact the dark nebulae are commonly found associated with bright stars and luminous nebulosity (diffuse nebulae), in such a way as to suggest irresistibly that they are physically connected and therefore at the same distance from us. The distances of some of these bright stars are known and are of the order of 400 light-years (a light-year is the distance that light travels in a year, about six million million miles). The dark nebulae connected with them must therefore be equally distant and their actual dimensions consequently very great, the dark lane in Ophiuchus being for example about 60 light-years long by 5 light-years wide. The region just south of the star ζ Orionis (Pl. I., fig. 2) is a typical example of the association of dark nebula, diffuse nebula, and stars. The left hand part of the field is covered by an obscuring cloud, and there are relatively few stars to be found in it. This cloud is edged with luminous nebulosity, of which there are also patches round the brighter stars. Beyond its boundary on the right the normal number of stars for a Milky Way region can be seen.

These clouds may be composed of particles of all sizes from mere molecules to bodies of almost stellar mass, but it seems clear from their obscuring power that they must contain a large amount of fine dust. For a given mass of matter the maximum obscuration is obtained when it is in the form of particles the circumferences of which are of the order of a wave-length of light (about one two-thousandth of a millimetre), and the whole of the obscuration of the large cloud in Ophiuchus could be produced by matter equal in mass to about 12 stars like our sun if it were in the form of minute particles of this optimum size.

Diffuse Nebulae.—These are similar to the dark nebulae, except that they are luminous, which fact enables us to learn a good deal more about them. Almost without exception they are found to have bright stars involved in them, and in many cases they are fringed with dark nebulosity. This suggests that the bright and dark nebulosities are parts of the same cloud, which the bright stars involved in it render luminous in their immediate vicinity. That this is at any rate sometimes the case was first suggested by the discovery by V. M. Slipher that the stars of the Pleiades and the nebulosity surrounding them had similar spectra.

More recently a systematic study of the diffuse nebulae by E. Hubble has brought to light a well-marked connection between the size of the luminous patch and the brightness of the star involved in it, the stars being found to illuminate the clouds around them to a distance proportional to their brightness. The method by which the clouds are made to shine cannot be always that of simple reflection of the star's light, because in many cases the nebulae shine with a different kind of light from that of the stars. Diffuse nebulae exist with both the continuous spectrum characteristic of the stars and with the bright-line spectrum which we have learned to associate with a rarified gas.

Only when the star involved in the nebula is an extremely hot one (spectral type B1 or earlier), does the nebula have a bright-line spectrum. When the star responsible for its light is of a cooler type the spectrum of the nebula is continuous and, in general, of the same type as that of the star. In this case the nebula may shine by reflection of the star's light. But the light of those nebulae which have gaseous spectra cannot be explained by simple reflection; it is necessary to postulate excitation of the dark cloud to luminosity in some other way (see the Gaseous Spectrum of Nebulae below). It appears then that a diffuse nebula is in general just a part of a dark cloud which is made luminous by the action of a star.

It is possible to determine with considerable accuracy the radial velocities (velocity in the line of sight) of those diffuse nebulae which show a gaseous spectrum, because their light though faint is concentrated in a few bright spectral lines; and it is found to be low, the average being about 11 kilom. a second. Owing, however, to the general absence in them of sharply defined points suitable for accurate measurement, it is a far more difficult matter to determine the motions, either of the nebula as a whole or of its constituent parts, across the line of sight. In fact, with the possible exception of the "Crab" nebula in Taurus, no change has been detected in the structure of a nebula. On looking for the first time at a photograph of such a nebula as the great one in the sword of Orion (Pl. I., fig. 1) one might well suppose that the internal motions of its parts would cause changes that would soon make a conspicuous alteration in its appearance. But when one considers its great distance (about 600 light-years), it is evident that sensible change of form could not be caused by motion at any reasonable velocities during the comparatively few years that the nebula has been studied by photography.

The same is true of all the diffuse nebulae, except the rare *variable nebulae*, of which the most remarkable are those in Monoceros and Corona Austrina (Nos. 2261 and 6729 in Dreyer's New General Catalogue). These two nebulae vary rapidly in both form and brightness, distinct differences being discernible in a few days. They are both fan-shaped, and each has a variable star at the apex of the fan. It is almost certain that the variations are caused, not by motion of the matter forming the nebulae, but by changes in the illumination of stationary nebulous matter emanating from the variable stars with which they are connected.

The density of the diffuse nebulae must be extremely low. Dynamical considerations suggest that in the case of the Orion nebula it cannot be greater than $1/1,000,000,000,000,000$ of the density of ordinary air; it may be much less. It is certainly a much more perfect vacuum than anything we can yet produce in our laboratories, yet so great is its size that it may contain enough matter to form thousands of stars as large as the sun.

Planetary Nebulae.—The planetary nebulae form quite a small class, there being less than 150 of them known; and, owing to the ease with which they can be recognised from their gaseous spectra, it is probable that we know of most that exist, and that they are therefore a comparatively rare form. A few of them are several minutes of arc in diameter, but the majority are so small that when viewed in the telescope they are indistinguishable from stars, except under a high power. They have the appearance of discs, round or nearly so in shape, with sharply defined edges and a faint star as nucleus. In many cases the disc is more luminous at its edge than in the centre, and the nebula has the appearance of a ring (Pl. I., figs. 3 and 4); whence they are sometimes called "annular nebulae." If they were actually discs, it is extremely

unlikely that we should see them all as circles. Their planes would naturally be inclined at various angles to our line of sight, and thus the discs would appear to us as ellipses of various degrees of elongation. Their real form is clearly spherical or nearly so; what appear to us as rings must be spherical shells, and the beautiful structure of ring within ring seen in some of these nebulae must be in reality a series of shell within shell.

The central stars of these nebulae are the bluest and hottest known (spectral class O), and there can be but little doubt that they are responsible for the light emitted by their nebulous envelopes, in a way similar to the excitation of luminosity in the diffuse gaseous nebulae by the hot stars involved in them. The planetary nebulae have as a class high radial velocities, averaging over 30 kilom. a second, higher than those of the Class O stars, which are not connected with nebulae, and consequently higher than stars of any spectral class; a few have radial velocities exceeding 100 kilom. a second. Exact determination of their motions across the line of sight is not easy, but it is clear that they are small, and that the average distance of these nebulae must be at least several hundred light-years. They are thus large bodies, several hundred times as large as the solar system.

The spectroscope has revealed that those which appear slightly flattened in form are rotating, and this is probably true in general. The periods of rotation must be reckoned in thousands of years. In some of them internal motions more complicated than a simple rotation have been detected by the spectroscope. Their densities seem to be very low, though perhaps not quite so low as those of the diffuse nebulae. Notwithstanding this their masses must be as large as those of the brightest stars.

The question as to what place, if any, the planetary nebulae take in the scheme of stellar evolution is a difficult one, to which at present there is no certain answer. Being so few in number, they cannot be regarded as forming a regular link in any evolutionary chain. It is possible that they are a later stage in the life history of the new stars (novae), which as they decline in brightness develop spectra of the same type as have the nuclei of planetary nebulae, and are also then usually surrounded by faint nebulous envelopes.

The Gaseous Spectrum of Nebulae.—The spectra of all gaseous nebulae are very similar, the differences consisting chiefly in the relative intensities of the bright lines. The lines in the spectrum are sharp, indicating that it is due to a gas of low density. The lines of hydrogen are prominent, and those of helium are usually present; but there are several lines, and among them are the strongest in the spectrum, which are so far unknown to us in our laboratories. These strong lines form a pair in the green region of the spectrum ($\lambda\lambda$ 5007, 4959) and a close pair in the ultra-violet ($\lambda\lambda$ 3726, 3729). The unidentified lines were originally ascribed to an element, unknown on earth, to which the name "Nebulium" was given, but it now seems clear that they are due to known elements in a state which has not yet been produced in the laboratory. This unfamiliar state may well be the extremely low density existing in these nebulae, far beyond anything we can produce in our vacuum tubes. Whereas in the latter the mean interval between atomic collisions is never more than one thousandth of a second, in the nebulae it may be as much as several minutes or even hours. I. S. Bowen has recently from theoretical considerations accounted for all the chief lines of "nebulium" in this way, the two strongest pairs being ascribed to ionised and doubly ionised oxygen in a "metastable" state.

All the lines of the nebular spectrum are characteristic of a form of radiation which requires a great amount of energy for its excitation. The source of this energy cannot be in the nebulae themselves, for that would postulate for them an impossibly high temperature. A possible source is the bombardment of the atoms of the nebula by electrons emitted by very hot bodies, and such bodies are to be found in all gaseous nebulae—the stars of spectral classes O and B, the hottest bodies known to us.

THE EXTRA-GALACTIC NEBULAE

General Characteristics.—The extra-galactic nebulae are found scattered all over the sky except in the Milky Way itself,

SPIRAL NEBULAE OR "ISLAND UNIVERSES"

1. Spiral Nebula In Andromeda (M. 31, N.G.C. No. 224)
2. Spiral Nebula in Ursa Major (M. 101, N.G.C. 5457)

which they rigidly avoid. This characteristic is, however, by no means the only thing that differentiates them from the galactic nebulae, and the most casual study soon shows them to be objects of quite a different nature. They vary in apparent size from the great spiral nebula in Andromeda, which is more than 2° long, to objects so small that only in the largest telescopes can they be distinguished from stars. Of these small nebulae there are several hundred thousand within our reach. They are too minute to show any structure, but of the larger objects a few are irregular in shape and bear some resemblance to the Magellanic Clouds, but in general the extra-galactic nebulae are remarkable for their symmetry of form. They appear as circular or elliptical objects and form a progressive sequence, from the *globular* or *elliptical*, nebulae, which are quite structureless, to the *spiral* nebulae, which show spiral structure in various degrees of development.

The globular nebulae show no signs of resolution into separate stars even in the most powerful telescopes. They get gradually brighter towards the centre and have no well defined edge, as have the planetary nebulae. They are found with all degrees of elongation from circular to spindle shapes, but it seems from the frequency of the circular form that many of them must be actually spherical or nearly so, though the majority may be lenticular in form. An example of a globular nebula can be seen in the lower left hand corner of the plate of the spiral nebula in Andromeda.

The chief characteristic of the typical spiral nebula is the emergence from opposite sides of its central nucleus of two spiral arms which wind themselves round it. Their forms are many and varied, some being very complicated and all very beautiful; but most of them can be graded into a sequence, with objects at one end differing but little from the structureless globular nebulae, and at the other end nebulae with highly developed spiral arms. At the beginning of this sequence the nucleus has all the characteristics of a globular nebula, but as progress is made along the sequence the nucleus becomes smaller and sharper in outline until at the other end it is almost stellar. The spiral arms, however, develop; unwinding themselves further and becoming more and more studded with condensations, which at the far end of the sequence can be resolved with the most powerful telescopes into separate stars.

It is tempting to suppose that this sequence gives us a picture of an evolutionary process, and that the spiral nebula actually develops from the structureless globular nebula to a final state of clusters of stars by the formation of spiral arms and the continued projection of the matter originally forming the globular nebula, or nucleus, along them. That such is a possible process in the case of a lenticular revolving mass, such as the globular nebula may be supposed to be, has been shown by J. H. Jeans, who by mathematical reasoning has traced out the whole sequence; how the nearly spherical and slowly rotating globular nebula spins faster as it contracts, and thus becomes more flattened; how the tides raised in it on opposite sides of its equator by some neighbouring nebula form protuberances, which are impelled forth as spiral arms; and how these arms as they emerge wind round the central mass and are disintegrated into groups of condensations which ultimately become stars. The process must be an extremely slow one as we reckon time, involving millions of millions of years, and we must not therefore expect to see in a lifetime much change in the form of a particular nebula. However, the spectroscope has shown that they are in rapid rotation, and, provided that they are not more distant from us than the galactic nebulae, it should be possible by comparing photographs taken only a few years apart to detect movements of the condensations in those nebulae which are turned so as to give us an open view of them.

The plates accompanying this article show two spiral nebulae, the great nebula in Andromeda, with its plane considerably tilted to us, coming comparatively early in the evolutionary sequence. Here the nucleus is large and the centre of the nebula structureless, and only in the outer parts are condensations beginning to form. The other plate shows an open view of a more developed spiral in Ursa Major. It has a much smaller nucleus and the spiral arms are full of condensations throughout their length, the outermost of them becoming stellar in character. Dark mark-

ings will be seen in the Andromeda nebula, and these are found in many of the spirals. They suggest irresistibly the presence of obscuring clouds similar to those seen in the Milky Way. Many of the extra-galactic nebulae which are seen edge-on are found to be crossed by dark bands, clearly caused by surrounding rings of dark matter hiding some of the luminous nebulousity nearer their nuclei. A typical example is N.C.G. 4594 for an illustration of which, and of several other spiral nebulae, see COSMOGONY.

Spectroscopic observation of the extra-galactic nebulae is difficult on account of their faintness, but the central parts of those that are sufficiently bright have all been found to show continuous spectra, crossed by absorption lines, similar in nature to those of stars like our sun. A few also show bright lines in their spectra; but these come from individual condensations, and not from the nebula as a whole. Thus these nebulae must be formed either of bodies similar to the stars or of matter that derives its light from stars involved in it, in a way similar to that postulated for those of the diffuse nebulae that show similar spectra.

The "Island Universe" Theory.—The question of the nature of the extra-galactic nebulae is intimately bound up with that of their distance, on which, of course, that of their actual dimensions depends. Are they members of our system of stars forming the Milky Way, or do they lie outside it, as globular clusters are believed to do?

The evidence available is preponderantly in favour of the extra-galactic nebulae lying outside our stellar system and even beyond the globular clusters. This means that they must be at immense distances, for we have reason to believe that the distance of some of the star clouds of the Milky Way is of the order of tens of thousands of light-years, and that the most distant of the globular clusters are 200,000 light-years away.

The velocities of these nebulae in the line of sight, revealed by the spectroscope, come out very large, the average being over 500 kilom. a second, many times that of any of the bodies within our galactic system. They also appear almost without exception to be receding from us. No entirely satisfactory explanation of this is yet forthcoming, but it seems possible that these observations do not represent real velocities of the nebulae. There are reasons, derived from the general theory of relativity, for supposing that extremely distant bodies might appear to be receding rapidly from us. Whatever is the final interpretation of these observations, they differentiate the extra-galactic nebulae from any bodies in our stellar system.

During recent years several examples of two types of variable star, which otherwise are only found closely confined to the plane of the Milky Way, have been discovered in some of the larger spirals. As there are none of these stars in the regions around, it seems certain that they lie actually in the nebulae and are not merely seen projected on them. These variables are of the kind known as Cepheids, or are novae (new stars). The Cepheid variables in the Galaxy have the peculiarity that their periods of variation are closely correlated with their actual luminosities, whence from a knowledge of the period and the apparent brightness of such a star, both easily observable quantities, its distance can be inferred. Assuming that the Cepheids found in the spirals are of the same nature as those in the Galaxy, and that consequently this law holds for them also, Hubble has determined the distances of the great spiral in Andromeda and of that in Triangulum to be each of the order of 900,000 light-years. These distances are confirmed by the brightness, when at their maximum luminosity, of the novae in them, if we may assume that this will be on the average the same as it is with those in the Galaxy. And these are the two largest and most conspicuous of the spiral nebulae, and therefore may be among the nearest to us.

The evidence then points unmistakably to the extra-galactic nebulae being bodies at truly immense distances, reckoned in millions of light-years, and in some cases perhaps in tens of millions; for, though on this point we have as yet no certain knowledge, it is possible that all these bodies are of much the same size, the minute apparent size of so many of them being only the effect of immense distance. They must then be of vast actual dimensions, comparable to, though apparently not quite so large

as, our own stellar system, which they resemble in so many ways; in their lenticular shape; in their colour, their spectra being similar to the integrated spectrum of the Milky Way; in the presence in them of dark clouds of obscuring matter; and in the resolvability of the more advanced of them into separate stars, which seem similar in character to those in our stellar system. The absence of a nucleus in our own system shows, however, that it is not a typical spiral nebula, as does the much greater brightness of the central parts of even the advanced type of spirals.

Thus the problem of the nature of the extra-galactic nebulae seems definitely settled in favour of the "island universe" theory, as the supposition that they are bodies external to our own stellar universe has been called. But as H. Shapley, who has made a special study of the structure of the universe, has said "If we call them islands, the galaxy is a continent." There is no sign of the nebulae thinning out as far as we can penetrate space, and we must picture the whole of known space as an ocean filled with these island universes, and our own stellar system among them but of sufficiently greater size to deserve the more dignified appellation of continent. It is a stupendous thought that the light which now reaches us from the outermost parts of this cosmos started on its journey millions of years ago, and that our photographs of these distant universes give us pictures of them, not as they are now, but as they were before the dawn of the human race on this small earth of ours. But then in the ages occupied by stellar evolution a million years is but a day.

BIBLIOGRAPHY.—Numerous photographs of nebulae will be found in Isaac Roberts, *Photographs of Stars, Star Clusters, & Nebulae* (1893-99); *Publications of the Lick Observatory*, vol. viii. 1908, and vol. xiii. 1918. The best and most up-to-date general account of them is in Russell, Dugan & Stewart, *Astronomy*, vol. ii. 1926. Numerous papers by E. Hubble in recent volumes of the *Astrophysical Journal*.

NEBULAR THEORY: see COSMOGONY.

NECESSITY: see FREEWILL.

NECK, that part of the body which connects the head with the trunk (see ANATOMY: *Superficial and Artistic*). The word is transferred to many objects resembling this part of the body in shape or function; it is thus applied to an isthmus, or to the narrowest portion of a promontory, to the narrow part of a musical stringed instrument connecting the head and body, as in the violin, or to a narrow pass between mountains, which in the Dutch form *nek*, appears in place-names in South Africa. In architecture, the "neck" is that part of the capital just above the "astragal," and the term "necking" is applied to the annulet or round, or series of horizontal mouldings, which separates the capital of a column from the plain part or shaft. In Romanesque work this is sometimes corded.

In Geology, the term "neck" is given to the denuded stump of an extinct volcano. Beneath every volcano there are passages or conduits up which the volcanic materials were forced, and after the mass has been levelled by denudation there is always a more or less circular pipe which marks the site of the crater. This pipe, filled with ashes or lava, is the characteristic of a volcanic neck. Many instances are furnished by the geological history of the British Isles. In Derbyshire, Fife, the Lothians and the Glasgow district the remains of Carboniferous volcanoes occur in every state of preservation. Some have the conical hills of lavas and ashes well preserved (e.g., Largo Law in Fifeshire); others retain only a small part of the original volcanic pile (e.g., Arthur's Seat, Edinburgh; the Binn of Burntisland) and of the larger number nothing remains but the "neck" which shows where once the crater was situated.

In regions of former volcanic activity necks are the most persistent of all volcanic structures, because the active volcanic magma is located deep within the earth's crust, and the pipe by which it rises to the surface is of great length and traverses a great thickness of strata. This extensive pipe was usually vertical, and nearly uniform in diameter for great depths; when exposed by denudation, it has a circular ground plan, or if shown in vertical section (or elevation) in a cliff is a pillar-shaped mass crossing the bedding planes of the strata nearly at right angles. It terminates upwards, in the remains of the volcanic cone and com-

municates below with the reservoir from which the lavas were emitted, represented in most cases, where it has been exposed, by a large irregular mass (a batholith or boss) of coarsely crystalline igneous rock. The site of such a neck is generally indicated by a low conical hill consisting of volcanic rock, surrounded by sedimentary or igneous strata of a different kind. The low cone is due to the greater hardness and strength of the volcanic materials and is not connected with the original shape of the volcano. Two splendid sugar-loaf cones known as the Pitons of St. Lucia in the West Indies, rising from the sea with almost vertical sides to a height of nearly 3,000ft., are old volcanic necks. In Texas, New Mexico, Arizona, California and many of the western states of North America, geologists have observed conical volcanic hills having all the features which belong to necks.

Where the volcanic rocks are soft and easily disintegrated the position of a neck may be indicated by a cup-shaped hollow; this is the case with some of the diamond-bearing basic pipes of South Africa. Examples are the Kimberley diamond mines. The blue-ground (or serpentine breccia) occupies great pipes or funnels, circular in outline with nearly vertical sides, extending downwards to unknown depths; these are the necks of the old volcanoes.

The size of necks varies considerably; the smallest may be only 20 or 30yd. in diameter, the largest are several miles. In this respect they resemble active craters, but no necks have been met with on the earth's surface with dimensions approaching those of the so-called "craters" of the moon.

Occasionally a whole neck is composed of solid crystalline rock representing the last part of the magma which ascended from the underground focus and congealed within the crater. In Mont Pelée, for instance, the last stage of the eruptions of 1902 to 1905 was the protrusion of a great column of solidified lava which rose at one time to a height of 900ft. above the lip of the crater, but has since crumbled down. The Castle Rock of Edinburgh is a neck occupied by a plug of crystalline basalt. Necks of this kind weather down very slowly and tend to form prominent hills.

After the eruptions terminate gases or hot solutions given out by deep-lying masses of molten rock may find a passage upward through the materials occupying the crater, greatly modifying their mineral nature and laying down fresh deposits. A good example of secondary deposits within a volcanic neck is provided by the Cripple Creek mining district of Colorado. The ore-bearing veins are connected with volcanic rocks and part of these occupy a vertical circular pipe which is a typical volcanic neck. A phonolitic breccia, greatly altered, is the principal rock, and is cut by dikes of phonolite, dolerite, etc. The country rock is mostly granite and gneiss, and blocks of these are common in the breccia. A large volcano was built up in Tertiary times on the granite plateau, and has since been almost entirely removed by denudation. The gold ores were carried upwards by currents of hot water derived from the volcanic magma and were deposited along cracks and fissures in the materials which occupied the crater, and also in the surrounding rocks (see VOLCANO).

(J. S. F.)

NECKAM, ALEXANDER (1157-1217), English schoolman and man of science, was born at St. Albans in September 1157, on the same night as King Richard I. Neckam's mother nursed the prince with her own son, who thus became Richard's foster-brother. He was educated at St. Albans Abbey school, and became schoolmaster of Dunstable, dependent on St. Albans Abbey. Later he went to Paris, where by 1180 he had become a distinguished lecturer of the university. By 1186 he was back in England, where he again held the place of schoolmaster at Dunstable. The assertion that he was ever prior of St. Nicolas, Exeter, seems a mistake, but he was certainly much at court during some part of his life. Having become an Augustinian canon, he was appointed abbot of Cirencester in 1213. He died at Kempsey in Worcestershire in 1217, and was buried at Worcester. Besides theology he studied grammar and natural history, but his name is chiefly associated with nautical science. For in his *De naturis rerum* and *De utensilibus* (the former of which, at any rate, had become well known at the end of the 12th century, and was probably written about 1180) Neckam has preserved to us the earliest European notices of the magnet as a guide to seamen—outside China, indeed,

these seem to be the earliest notices that have survived in any country or civilization. It was probably in Paris that Neckam heard how a ship, among its other stores, must have a needle placed above a magnet (the *De utensilibus* assumes a needle mounted on a pivot), which needle would revolve until its point looked north, and thus guide sailors in murky weather or on starless nights. Neckam has no air of imparting a startling novelty: he merely records what had apparently become the regular practice of many seamen of the Catholic world.

See Thomas Wright's edition of Neckam's *De naturis rerum* and *De laudibus divinae sapientiae* in the Rolls Series (1863), and of the *De utensilibus* in his *Volume of Vocabularies*. Neckam also wrote *Corrogationes Promethei*, a scriptural commentary prefaced by a treatise on grammatical criticism; a translation of Aescop into Latin elegiacs (six fables from this version, as given in a Paris ms., are printed in Robert's *Fables inédites*); commentaries, still unprinted, on portions of Aristotle, Martianus Capella and Ovid's *Metamorphoses*, and other works. Of all these the *De nat. rer.*, a sort of manual of the scientific knowledge of the 12th century, is much the most important: the magnet passage herein is in book ii. chap. xcvi. (*De vi attractiva*), p. 183 of Wright's edition. The corresponding section in the *De utensil.*, is on p. 114 of the *Vol. of Vocab.* Roger Bacon's reference to Neckam as a grammatical writer (*in multis vera et utilia scripsit: sed . . . inter auctores non potest . . . numerari*) may be found in Brewer's (Rolls Series) edition of Bacon's *Opera inedita*, p. 457. See also Thomas Wright, *Biographia Britannica literaria, Anglo-Norman Period*, pp. 449-459 (1846: some points in this are modified in the 1863 edition of *De nat. rer.*); C. Raymond Beazley, *Dawn of Modern Geography*, iii. 508-509. (C. R. B.; X.)

NECKAR, a river of Germany, 247 m. long, and a right-bank tributary of the Rhine, rises in the Hercynian gneisses of the Black forest, near Schwenningen and close to the headwaters of the Danube. It flows north and then north-east along the foot of the Jurassic scarp of the Swabian Jura, passing Rottweil, Rottenburg, and Tübingen. At Plochingen it changes its course flowing away from the scarp edge to Cannstatt near Stuttgart. The valley is very picturesque, becomes broader and deeper, is now navigable and lies between vine-clad hills being cut into the middle Trias sandstones. Continuing north past hills crowned by feudal castles, it runs by Heilbronn and Wimpfen to Eberbach. It now takes a tortuous westerly course, and the scenery on its bank becomes more romantic. Winding by Neckarsteinach and Neckargemünd between wooded heights, it sweeps beneath the Königsstuhl (1,900 ft.) washes the walls of Heidelberg, and quitting the valley enters the Rhine-trough from the right at Mannheim. (See RHINE.)

NECKER, JACQUES (1732-1804), French statesman, finance minister of Louis XVI., was born at Geneva in Switzerland. His father was a native of Cüstrin in Pomerania, and became a citizen of Geneva. Jacques Necker had been sent to Paris in 1747 to become a clerk in the bank of M. Vernet. He soon afterwards established the famous bank of Thellusson and Necker. Thellusson superintended the bank in London, and Necker the Paris branch. Both became extremely rich by loans to the treasury and speculations in grain. In 1763 Necker fell in love with Madame de Verménou, the widow of a French officer. But while on a visit to Geneva, Madame de Verménou met Suzanne Curchod, the daughter of a pastor near Lausanne, to whom Gibbon had been engaged, and brought her to Paris in 1764. Necker married Suzanne before the end of the year. She encouraged her husband to make himself a public position. He accordingly became an able director of the French East India Company, and defended it against the attacks of A. Morellet in 1769. Meanwhile he had made interest with the French government by lending it money, and was appointed resident at Paris by the republic of Geneva. Madame Necker entertained the chief leaders of the political, financial and literary worlds of Paris. In 1773 Necker won the prize of the Académie Française for an *éloge* on Colbert, and in 1775 published his *Essai sur la législation et le commerce des grains*, in which he attacked the free-trade policy of Turgot. His wife believed he could get into office as a great financier, and made him transfer his share in the bank to his brother Louis.

In October 1776 Necker was made finance minister of France, with the title of director of the treasury, which he changed in

1777 to director-general of the finances. He regulated the finances by attempting to divide the *taille* or poll tax more equally, by abolishing the "vingtième d'industrie," and establishing *monts de piété* (establishments for loaning money on security). But his greatest financial measures were his attempt to fund the French debt and his establishment of annuities under the guarantee of the state. In the operation of funding Necker rather pointed out the line to be followed than completed the operation. He treated French finance rather as a banker than as a political economist, and thus fell far short of Turgot, the greatest economist of his day. His establishment of provincial assemblies was only a timid application of Turgot's great scheme for the administrative reorganization of France. In 1781 he published his famous *Compte rendu*, in which he drew up the balance sheet of France. His dismissal in the same year was not really due to his book, but to the influence of Marie Antoinette, whose schemes for benefiting the *duc de Guines* he had thwarted.

In 1787 Necker was banished by "lettre de cachet" 40 leagues from Paris for attacking Calonne. In 1788 the country, which had at the bidding of the literary guests of Madame Necker come to believe that Necker was the only minister who could "stop the deficit," as they said, demanded Necker's recall, and in September 1788 he became once more director-general of the finances. Throughout the momentous months which followed the biography of Necker is part of the history of the French Revolution (*q.v.*). Necker put a stop to the rebellion in Dauphiné by legalizing its assembly, and then arranged for the summons of the states general. Throughout the early months of 1789 he was regarded as the saviour of France, but he regarded the states general as an assembly which should grant money, not organize reforms. But as he had advised the calling of the states general, and the double representation of the third estate, and then permitted the orders to deliberate and vote in common, he was regarded as the cause of the Revolution by the court, and on July 11 was ordered to leave France at once.

Necker's dismissal brought about the taking of the Bastille, which induced the king to recall him. He was received with joy in every city he traversed, but in Paris he proved himself unequal to the crisis. After his resignation (Sept. 1790) he lived at Coppet, near Geneva. Madame Necker died in 1794, and he lived with his daughter Madame de Staël (*q.v.*), and his niece, Madame Necker de Saussure. He died in 1804.

AUTHORITIES.—*Mémoires sur la vie privée de M. Necker* (Paris and London, 1818), by his daughter, Madame de Staël-Holstein, and the *Notice sur la vie de M. Necker* (Paris, 1820), by Auguste de Staël-Holstein, his grandson, published in the collection of his works edited by the latter in 1820-1821 (Paris, 15 vols.). The bibliography of his works is as follows:—*Réponse au mémoire de M. l'abbé Morellet* (1769); *Eloge de J. B. Colbert* (1773); *Essai sur la législation et le commerce des grains* (1775); *Compte rendu au roi* (1781); *De l'administration des finances de la France* (3 vols., 1784); *Mémoire en réponse au discours prononcé par M. de Calonne* (1787); *De l'importance des opinions religieuses* (1788); *Sur l'administration de M. Necker, par lui-même* (1791); *Du pouvoir exécutif dans les grands états* (2 vols., 1792); *Réflexions sur le procès de Louis XVI.* (1792); *De la révolution française*, several editions, the last in 4 vols. (1797); *Cours de la morale religieuse* (1800); *Dernières vues de politique et de finance* (1802); *Manuscrits de M. Necker*, published by his daughter (1804); *Suites funestes d'une seule faute*, published after his death. See also *Le Salon de Madame Necker*, by the Vicomte d'Haussonville (2 vols., 1882), compiled from the papers at Coppet; Ch. Gomel, *Les Causes financières de la révolution française* (1892); and for contemporary tracts and pamphlets M. Tourneux, *Bibl. de l'histoire de Paris pendant la révolution* (vol. iv., 1906), also (for the earlier ones) *Collection complète de tous les ouvrages pour et contre M. Necker, avec des notes critiques* . . . (3 vols., Utrecht, 1781); Gambier Parry, *Mme. Necker, her Family and her Friends* (1913).

NECKING, in architecture, a narrow, horizontal band around a pier, pilaster, column or similar vertical form; especially the band which circles a Doric capital below the echinus or projecting portion, and above the astragal, or projecting moulding, which marks the junction of shaft and capital.

NECROPOLIS, a cemetery (*q.v.*) or burying-place (Gr. νεκρός, corpse, and πόλις, city).

NECROSIS, a term restricted in surgery to death of the whole or a portion of a bone. A severe inflammation, caused by

a violent blow, by the action of pyogenic microbes as in osteomyelitis or by the absorption of various poisons, as mercury and phosphorus, is the general precursor of necrosis. The dead part analogous to the slough in the soft tissues, is called a sequestrum or exfoliation. At first it is firmly attached to the living bone around; gradually, however, the dead portion is separated from the living tissue. The process of separation is a slow one. New bone is formed around the sequestrum, which often renders its removal difficult. As a rule the surgeon waits until the dead part is loose, and then cuts down through the new case and removes the sequestrum. The cavity in which it lay gradually closes, and a useful limb is the result. In pathology the term is given a wider meaning and is used for local death of a portion of any tissue; when the death is of individual cells, and therefore is microscopic, it is often termed molecular necrosis or necrobiosis.

NECTAR and **AMBROSIA** (*q.v.*), the nourishment of the gods in Homer and in Greek literature generally. Probably the two terms were not originally distinguished; but usually, both in Homer and in later writers, nectar is the drink and ambrosia the food. On the other hand, in Alcan nectar is the food, and in Sappho and Anaxandrides ambrosia the drink. Each is used in Homer as a fragrant unguent (as *Iliad*, xiv. 170; xix. 38).

NECTARINE, a smooth-skinned peach (*q.v.*). Besides lacking the fuzz found on peaches, the fruits of nectarines are usually smaller, have firmer flesh, more aroma and a richer flavour. There are cling-stone and free-stone nectarines; like peaches they may have red, yellow or white flesh; the stones and kernels of the two fruits are indistinguishable, nor do nectarine trees differ from peach trees in any character. They are adapted to the same soil and climatic conditions and require the same care in the orchard.

The nectarine, which has been known for 2,000 years, is the classical example of bud and seed variation.

NEED-FIRE or **WILD-FIRE**, a term of folk-lore to denote a superstition which survived in the Highlands of Scotland until a recent date and had its origin in the early ideas of the purifying nature of flame. The need- or wild-fire is made by the friction of one piece of wood on another, or of a rope upon a stake. It is a practice of shepherd peoples to ward off disease from their herds and flocks; it is kindled on occasions of special distress, and the cattle are driven through it. Its efficacy is believed to depend on all other fires being extinguished (Pröhle, *Harz-Bilder*, Leipzig, 1855; Kelly, *Curiosities of Indo-European Tradition and Folklore*, p. 53 *seq.*).

NEEDHAM, town of Norfolk county, Massachusetts, U.S.A., 12 m. S.W. of Boston, on the Charles river, and served by the New York, New Haven and Hartford railroad. Pop. (1925) 8,977 (State census). It is a residential suburb and has large factories making knit goods and surgical instruments. The town was set off from Dedham and incorporated in 1711.

NEEDLE. An instrument adapted for passing a thread through fabrics in sewing, consisting of a thin rod of steel, having a pointed end and pierced with a hole or "eye" to carry the thread.

The modern high quality needle is made from Sheffield crucible cast steel. The type of steel varies according to the purpose of the needle, thus hosiery needles are milder, *i.e.*, softer than sewing needles. In addition to grading the initial hardness of the steel to the particular type of needle there has also been a forward movement in the use of alloy steels for specific purposes. Thus with gramophone needles tungsten alloy steels have proved successful, and the high chromium or non-rustless steels have a very evident value in the case of surgical and hypodermic needles. The steel is hot rolled down into rod and the rod subsequently cold drawn into wire of the required diameter. The finished drawn wire is fed through straightening machines which also automatically cut the wire into pre-determined lengths. In hand sewing needles the length cut is always that required to form two needles. The cut lengths are packed in packets of a standard weight, according to diameter of wire, for delivery to the needle maker.

The first stage in the making of the needle is to secure absolute straightness and uniformity of physical condition. This is achieved by a method technically termed "rubbing." A number of blanks are heated to a uniform dull red heat, placed within two steel rings, and rubbed to and fro over a flat steel plate. The rotation of the wires within the containing rings results in perfect straightness and the gradual cooling from a dull red heat gives uniformity of physical condition.

The lengths are then automatically pointed by feeding from a container and being rotated over a revolving grindstone by a wheel running at right angles to the stone. The curvature of the face of the grindstone and the inclination of the traversing wheel are adjusted to the requisite contour of point. The lengths are reversed and the process repeated—thus giving a blank with two pointed ends. This automatic grinding applies to all hand sewing needles; it should be noted that machine needle points are swaged, *i.e.*, the points are formed by cold hammering between dies. The double length hand needle is fed into an automatic press which stamps the grooves at the head of each needle and in a second operation pierces the eyes of each needle and nearly separates the two. Complete separation and dressing of the head and eye are now effected mechanically.

The needle thus formed is in its soft state and as with steel cutting tools it requires hardening to bring it into service condition. Hardening is effected by quenching in oil from a red heat and in practice the operation has become nearly automatic. The hardened needles are then tempered by heating to a blue heat in order to give resilience or springiness. As with hardening, tempering in bulk is now an automatic process. The tempered needles are to some extent discoloured by the heating and the final stages are found in scouring to remove this discolouration, and polishing to obtain the silver bright finish. Scouring is effected by packing the needles in flexible containers with various mixtures all having a fine emery base and mechanically rolling the container up and down an iron roller path. Polishing is done in a similar manner with polishing reagents replacing the scouring mixtures. The polished needles are rolled down an inclined plane to bring the heads all in one direction; examined; graded, and made up into packets for sale. (P. Lo.)

NEEDLE-GUN, a military breech-loading rifle (*Zündnadelgewehr*), famous as the arm of the Prussians in 1866 and of the Germans in 1870-71. It was the invention of the gunsmith Johann Nicholas von Dreyse (1787-1867), who, beginning in 1824, had made many experiments, and in 1836 produced the complete needle-gun. From 1841 onwards the new arm was gradually introduced into the Prussian service, and later into the military forces of many other German states. Dreyse was ennobled in 1864. In practice the needle-gun proved to have numerous defects; its effective range was very short compared to that of the muzzle-loading rifles of the day, and conspicuously so as against the chassepot; the escape of gas at the breech was, moreover, very great. A paper cartridge was used. An improved model, giving greater muzzle velocity and increased speed in loading, was introduced later, but this was soon replaced by the Mauser rifle.

NEEDLEWORK. This subject may be considered under the two headings: (1) plain needlework, for purely utilitarian purposes; (2) art needlework, for decorative purposes. Plain needlework requires no such further explanation as may be given in the case of art needlework, under which title are included embroidery and other methods of decorative needlework, such as applied or appliqué work, ornamental quilting, patchwork and couching. In these last-mentioned methods the needlework is subservient to the decorative effect, which depends almost wholly upon the materials selected for the purpose; whereas in embroidery the needlework itself constitutes and is the visible decoration. The aim of this article is to indicate briefly different stitches of plain needlework and to show that these stitches are also used in art needlework.

The more necessary stitches in plain needlework for making clothes are tacking, running, hemming, feather-stitching or herring-boning (all of which are practically of the same type), and button-holing in which the thread is looped as each stitch is

made. Button-holing is allied to another looped stitch, namely chain-stitching, which though frequently used in embroidery is rarely if ever used in plain needlework. For repairs of clothes and household linen, etc., the principal stitch is darning; grafting, however, is a substitute for it, and varies with the character of the stuff to be repaired, e.g., knitted stockings, damask linen, cloth, etc. Darning is allied to running, and grafting to patchwork. Patchwork as a form of decorative needlework is exemplified in sumptuous canopies and seat covers made several centuries B.C. by Egyptians, and rich hangings made by Italian and French workers in the 16th century.

Long and short stitches, kindred in principle to the running stitch in plain needlework, are perhaps the more frequent of any stitches used in embroidery, and are especially appropriate when the blending of tints with a flat even surface is the effect to be aimed at. Much mediaeval work of this character, as well as that done with chain stitch and its allied split stitch, is regarded as typical of *opus anglicanum*. Chain stitch produces a comparatively broken surface in decided contrast with the smooth one of long and short stitch, split stitch and satin stitch embroidery. Satin stitch is well adapted to express, with even flat surface in designs for colour effects, each mass which is to be of one tint. In this respect, therefore, satin stitch serves a purpose in contrast to that of long and short stitch. A characteristic of satin-stitching is the sheeny effect produced, on both sides of the material embroidered, by parallel stitches taken closely together. Buttonhole stitch in relation to art needlework prevails to a great extent in cut linen and drawn-thread work (often called Greek lace), and predominates in the making of needlepoint lace. In much of the Persian drawn-thread work, however, it is superseded by whipping or tightly and closely twisting a thread round the undrawn threads of the linen. Whipping has been put to another use in certain 16th century art needlework for ecclesiastical purposes, where round the gold threads employed as the ground of a design coloured silks are dexterously whipped, closely and openly, producing gradations of tint suffused with a corresponding variation of golden shimmer.

Another important branch of art needlework with gold and silver threads is couching. When the metallic threads, arranged so as to lie closely together, are simply stitched flatly to the foundation material, the work is called flat couching or laying, a kind of treatment more frequent in Chinese and Japanese than in European art needlework. Flat couching is also carried out with floss silks. When a design for couching includes effects in relief, stout strings or cords as required by the design are first fastened to the foundation materials, and over them the metallic threads or in some cases coloured gimps are laid, and so stitched as to appear in miniature like varieties of willow-twisting or basket work.

Appliqué or applied work belongs as much as patchwork to the mediaeval category of *opus consutum*, or stitching stuffs together according to a decorative design, the greater part of which was cut out of material different in colour, and generally in texture, from that of the ground to which it was applied and stitched. Irish art needlework, called Carrickmacross lace, is for the most part of cambric applied or appliqué to net.

Quilting is also a branch of art needlework rather than embroidery. Indians and Persians using a short running stitch have excelled in it in past times. Some good quilting was done in England in the 18th century with chain-stitching which lay on the inner side of the stuff, the outer displaying the design in short stitches. In the account of his voyage to the East Indies, published in 1655, Edward Terry (1590-1665) writes of the Indians "making excellent quilts of satin lined with taffeta betwixt which they put cotton wool and worked them together with silk." In many of the rural sections of the United States, especially those of the South, great interest has been maintained in making patch quilts for bed covering. Quilting parties are still extant, and the different designs accumulated by the family are the source of much pride. (See also LACE; HOME SEWING; TEXTILES AND EMBROIDERIES.)

(1921); E. L. Lowes, *Chats on Old Lace and Needlework*.

NEEMUCH or **NIMACH**, a town of Central India, with a British military cantonment, within the state of Gwalior, on the border of Rajputana. The pop. of the cantonment in 1921 was 10,490. In 1857 it was the most southerly place to which the Mutiny extended. The brigade of Indian troops of the Bengal army, which was stationed there, mutinied and marched to Delhi, the European officers taking refuge in the fort, until relieved by the Malwa field force. Since 1895 it has been the headquarters of the political agent in Malwa.

NEENAH, a city of Winnebago county, Wisconsin, U.S.A., 35 m. N. by W. of Milwaukee, on Lake Winnebago at its outlet into the (canalized) Fox river. It is on Federal highway 41, and is served by the Chicago and North Western, the Chicago, Milwaukee, St. Paul and Pacific, and the Soo Line railways, and by river steamers. Pop. (1920) 7,171 (84% native white). Neenah and Menasha, across the river, are practically one community. It is the centre of a large cheese industry. The city was chartered in 1873. Its name means "running water" or "rapids."

NEER, VAN DER, the name of two Dutch painters.

1. **AERNOUT VAN DER NEER** (1603-1677), commonly called Aert or Artus, was born at Gorkum in 1603. Houbraken states that he had been steward to a Dutch nobleman, and only took up painting seriously when he settled in Amsterdam. From 1658 to 1662 he kept a wine shop, but this venture ended in bankruptcy. Though Van der Neer seems to have made Amsterdam his home, he was evidently familiar with the canals and woods about Haarlem and Leyden and the reaches of the Maes and the Rhine. Occasionally, too, he painted in the neighbourhood of Dort, the home of Albert Cuyp, with whom he drifted into a curious partnership. Cuyp is said to have painted the foreground and cows of Van der Neer's sunset landscape in the Louvre and his signature is seen on the milkmaid's pail near the edge of the Van der Neer in the National Gallery, London. At the Städel Institute in Frankfurt there is also a landscape in which the figures, a fisherman with a dog and a sportsman, are probably by Cuyp. Van der Neer may be said to have reached maturity with his "Moonlit landscape with a ruined castle" (1646), now in the Max Flersheim collection in Paris. His favourite subjects were the Dutch waterways at sunset; moonlight scenes; daylight icescapes with frozen water, sleighs and fishermen; and paintings of fires after dark.

2. **EGLON VAN DER NEER** (1634-1703), son of the above, was born at Amsterdam in 1634. He was first taught by his father and afterwards by Jacob van Loo, whom he accompanied or followed to Paris in 1663. In 1666 he went to Rotterdam, from there to Brussels and finally to Düsseldorf, where he entered the service of the elector-palatine Johann Wilhelm. Later, a portrait of the princess of Neuberg led to his appointment as painter to the king of Spain. He painted landscapes in the style of Adam Elsheimer and was one of three painters employed to put figures into the town views of Jan van der Heyden. His portraits are reminiscent of Netscher and his genre pictures come near to those of Ter Borch and Metsu in delicacy of touch. The "Lady with the Book" (1665) was sold together with the Bredel collection in 1875. A young woman in white and red satin at Rotterdam (1669) recalls Mieris, whose style also reappears in Eglog's "Cleopatra" at Buckingham Palace. Two landscapes with "Tobit and the Angel," dated 1685 and 1694, in the museums of Berlin and Amsterdam, illustrate his fashion of setting Scripture scenes in Dutch backgrounds. His most important sacred composition is the "Esther and Ahasuerus" (1696), in the Uffizi at Florence. But Eglog varied his practice also with arrangements of hunting and hawking parties, pastures and fords. The latest of his panels is a mountain landscape of 1702 in the gallery of Augsburg. He died at Düsseldorf on May 3, 1703.

(J. A. C.; X.)

NEERWINDEN, a village of Belgium in the province of Liège, a few miles E. by S. of Tirlemont, which gives its name to two great battles, the first fought in 1693 between the Anglo-Allied army under William III. of England and the French under the duke of Luxembourg (see GRAND ALLIANCE, WAR OF THE) and

the second in 1793 between the Austrians under Prince Josias of Coburg and the French under General Dumouriez.

NEES VON ESENBECK, CHRISTIAN GOTTFRIED (1776-1858), German botanist and entomologist, was born at Erbach on Feb. 14, 1776, and was educated at Darmstadt and at Jena, where he took the degree of M.D. After practising as a doctor, he was appointed professor of botany in Erlangen in 1816. Three years later he became professor of natural history in Bonn, and in 1831 he was appointed to the chair of botany in the university of Breslau. For his political activities in 1848, he was deprived of his professorship in 1851, and after spending the rest of his life in poverty, he died in Breslau on March 16, 1858.

For some years he edited the *Nova acta* of the "Acad. Leopoldo-Carolina," in which several of his own papers were published. His best-known works are those that deal with the *Fungi*, the *Hepaticae* and the *Glumiferae*, in all which groups he made valuable additions to knowledge.

NEGAPATAM, a seaport of British India, in the Tanjore district of Madras, forming one municipality with Nagore, a port 3 m. N. at the mouth of the Vettar river. Pop. (1921) 54,016. It carries on a brisk trade with the Straits Settlements and coast ports, steamers running fortnightly to the Straits. Ground nuts, cotton goods, tobacco and vegetables are exported. Vessels lie 2 m. off shore. Negapatam is the terminus of a branch of the South Indian railway, with large railway workshops, and has two technical institutes. It is also a depot for coolie emigration. Negapatam was one of the earliest settlements of the Portuguese on the Coromandel coast. It was taken by the Dutch in 1660, becoming their chief possession in India, and by the English in 1781. From 1799 to 1845 it was the headquarters of Tanjore district.

NEGAUNEE (nē-gaw'ne), a city of Marquette county, Michigan, U.S.A., 12 m. W. by S. of Marquette, near Lake Superior, at an altitude of 1,564 ft. It is on federal highway 41, and is served by the Chicago and North Western, the Duluth, South Shore and Atlantic and the Lake Superior and Ishpeming railways. The population was 7,419 in 1920 (33% foreign-born white). It is one of the important mining centres of the Upper Peninsula, surrounded by iron mines of both the deep-shaft and the open-pit type. A monument marks the spot where iron ore was first found (1844) in the Lake Superior region. Settlement here began about 1870 and the city was chartered in 1873. The name is a Chippewa word meaning "first" or "he goes before," chosen by the Pioneer Iron company as meaning "pioneer."

NEGLIGENCE, a ground of civil law liability, and in criminal law an element in several offences, the most conspicuous of which is manslaughter by negligence. In order to establish civil liability on the ground of negligence, three things must be proved—a duty to take care of, the absence of due care, and actual damage caused directly by the absence of due care. The duty may be to the public in general, on the ground that any person who does anything which may involve risk to the public is bound to take due care to avoid the risk. For instance, in the words of Lord Blackburn, "those who go personally or bring property where they know that they or it may come into collision with the persons or property of others have by law a duty cast upon them to use reasonable care and skill to avoid such a collision." Where a special duty to an individual is alleged, the duty must rest on a contract or undertaking or some similar specific ground. Thus, where a surveyor has carelessly given incorrect progress certificates, and a mortgagee who has had no contractual relation with the surveyor has advanced money on the faith of the certificate, the surveyor is not liable to the mortgagee in an action of negligence; because he owed no duty to the mortgagee to be careful. When a duty to take care is established, the degree of care required is now determined by a well-ascertained standard. This standard is the amount of care which would be exercised in the circumstances by an "average reasonable man."

Ordinarily a man is responsible only for his own negligence and for that of his servants and agents acting within the scope of their authority. For the acts or defaults of the servants of an independent contractor he is not liable. But in certain cases a stricter obligation is imposed on him by law. Thus, while the oc-

cupier of premises is under no duty whatsoever to trespassers, who must take the premises as they find them, and while he is under no duty to mere licensees other than the duty of seeing that there are no concealed dangers in the nature of traps, he is under a duty to invitees and to all persons entering as of right to see that the premises are in a reasonably safe condition so far as reasonable care and skill can make them so; and from such duties he cannot release himself by employing an independent contractor to maintain or repair the premises. The effect of this doctrine is that the occupier may be liable if it can be shown that the independent contractor or his servant has been guilty of a want of due care. A similar obligation has been enforced in the case of a wreck stranded in a navigable river, and the owner was held liable for damage caused by the carelessness of the servant of an independent contractor who had undertaken to light the wreck. So too any person who undertakes a work likely to cause danger if due care is not taken is liable for damage caused by the carelessness of the servant of an independent contractor, so long as the carelessness is not casual or collateral to the servant's employment.

In an action of negligence a familiar defence is "contributory negligence." This is a rather misleading expression. It is not a sufficient defence to show that the plaintiff was negligent, and that his negligence contributed to the harm complained of. The plaintiff's negligence will not disentitle him to recover unless it is such that without it the misfortune would not have happened, nor if the defendant might by the exercise of reasonable care on his part have avoided the consequences of the plaintiff's negligence. The shortest and plainest way of expressing this rule is, that the plaintiff's negligence is no defence unless it was the approximate or decisive cause of the injury. There was an attempt in recent times to extend this doctrine so as to make the contributory negligence of a third person a defence, in cases where the plaintiff, though not negligent himself, was travelling in a vehicle or vessel managed by the negligent third person, or was otherwise under his control. In such circumstances it was said that the plaintiff was "identified" with the third person. But the case of the "Bernina," decided in 1888, where a passenger and an engineer on board the "Bushire" were killed in a collision between the "Bernina" and the "Bushire" caused by fault in both ships, but without fault on the part of the deceased, exploded this supposed doctrine, and made it clear that the defence of contributory negligence holds good only when the defendant contends and proves that the plaintiff was injured by his own carelessness.

The American law of negligence is founded on the English common law; but the decisions in different States have occasionally contradicted English decisions, and also one another.

See T. G. Shearman and A. A. Redfield, *The Law of Negligence* (3rd ed., 1874); S. D. Thompson, *Commentaries on Negligence* (7 vols., Indianapolis, 1901-07); T. Beven, *Negligence in Law* (4th ed., 1928). (A. LL. D.)

NEGOTIABLE INSTRUMENT, in law, a document or other instrument purporting to represent an obligation involving so much money, and the property in which passes, like money, by mere delivery or by endorsement and delivery. Negotiable instruments arise in either of two ways: (1) by statute, (2) by custom of merchants. The most commonly recognized negotiable instruments are bills of exchange, promissory notes, bills of lading, foreign bonds, debentures payable to bearer, and endorsed share certificates, such as are issued in Canada and the United States. Negotiable instruments constitute an exception to the general rule that a man cannot give a better title than he has himself. (See BILL OF EXCHANGE.)

NEGRITOS (Span. for "little negroes"), the name originally given by the Spaniards to the aborigines of the Philippine Islands. They are physical weaklings, of low, almost dwarf, stature, with very dark skin, closely curling hair, flat noses, thick lips and large clumsy feet. The term is now applied to one of the elements of the population of S.E. Asia, Indonesia and Oceania. The true negritos are always of little stature (the majority under 5 ft.), have rounded forms and their skull is relatively short and broad and of little height. Their skin is dark brown or black.

sometimes somewhat yellowish, their hair woolly (scanty on face and body), and they have the flat nose and thick everted lips and other physical features of the negro. Among negrito peoples are the Andamanese (*q.v.*), the Semang, Malay Peninsula and E. Sumatra (*q.v.*), the best types being the Tapiro (New Guinea) and Aetas (Philippines). There is evidence, physical, cultural and traditional, of a negrito substratum in the population of Assam (*Man in India*, VII. 4. 1927), while traces have been found by Hüsing along the Persian gulf. It is therefore an old element which survives in purity only among the Andamanese.

See A. de Quatrefages, *Les Pygmées* (Paris, 1887; Eng. trans. 1895); A. R. Broman, *The Andaman Islanders* (1922); *Album von Philippinen-Typen* (Dresden, 1885); Blumentritt, *Ethnographie der Philippinen* (Gotha, 1892); A. B. Meyer, *Die Negritos* (Dresden, 1899); A. H. Keane, *Ethnology*; A. C. Haddon, *The Races of Man* (1924); Roland B. Dixon, *Racial History of Mankind* (1923).

NEGRO, the designation of the distinctly dark-skinned, as opposed to the fair, yellow and brown races of mankind (from Lat. *niger*, black). In this sense it embraces the dark races, of the intertropical and sub-tropical regions of the eastern hemisphere, from Senegambia, West Africa, to the Fijian islands in the Pacific. It is convenient, however, to refer to the dark-skinned inhabitants of this zone by the collective term of *Negroids*, and to reserve the word *Negro* for the tribes found in Africa south of the Sahara and north of a not very well-defined line running roughly from the gulf of Biafra with a south-easterly trend across the equator to the mouth of the Tana. The Bantu Negroids are south of this line. The yellowish-brown Bushman and Hottentot (*q.v.*) peoples of South Africa possess certain Negroid characters, the tightly curled hair, the broad nose, the tendency towards prognathism; but the relation is not close. The Negroids of Africa, Melanesia and Australasia have in common a number of characteristics such as:—A dark skin, varying from dark brown, reddish-brown or chocolate to nearly black; dark tightly curled hair, flat in transverse section, of the "woolly" or the "frizzly" type; a greater or less tendency to prognathism; eyes dark brown with yellowish cornea; nose more or less broad and flat; and large teeth. The Negro hair is flat, issues from the epidermis at a right angle, is spirally twisted or crisped, has no central duct, the colouring matter being disseminated through the cortex and intermediate fibres, while the cortex itself is covered with numerous rough, pointed filaments, adhering loosely to the shaft; lastly, the Negro pile will felt, like wool, whereas true hair cannot be felt. The true Negro (western Sudan type) is of tall stature, burly, short-legged, usually long-headed, with bulging forehead. A broad headed element of obscure origin extends across the continent. (For the Negro in the United States see **NEGRO, THE AMERICAN**.)

In Africa three races have intermingled to a certain extent with the Negro; the Libyans (Berbers, *q.v.*) in the Western Sudan; and the Hamitic races (*q.v.*) and Arabs (*q.v.*) in the east. The Bantu-speaking peoples in the southern portion of the continent approach the Hamites in those characteristics in which they differ from the true Negroes, and probably have a proportion of Hamitic blood.

The colour of the skin, which is also distinguished by a velvety surface and a characteristic odour, is due to the greater abundance of the colouring matter in the mucous membrane between the inner or true skin and the epidermis. This colouring matter is not distributed equally over the body, and does not reach its fullest development until some weeks after birth. The dark colour seems to depend neither on geographical position, the isothermals of greatest heat, nor even altogether on racial purity. The extremes of the chromatic scale are found in juxtaposition throughout the whole Negro domain, in Senegambia, the Gabun,

BY COURTESY OF THE HERLING NEW GUINEA EXPEDITION
NOGULLA NEGRO OF NEW GUINEA WITH HIS CLUB

upper Nile basin, lower Congo, Shari valley, Mozambique, ranging from dusky or yellow brown to sooty black. Some of the mixed races, such as many Abyssinians, Galla, Jolof and Mandingo, are quite as black as the darkest full-blood Negro. The development of pigment in the dark-skinned races as a natural protection against the ultra-violet rays in which tropical light is so rich must be viewed as merely a part of a many sided modification of the skin under torrid conditions.

In certain of these characteristics the Negro stands on a lower evolutionary plane than the white man, and is closely related to the highest anthropoids. The characteristics are length of arm, prognathism, a heavy massive cranium with large zygomatic arches, flat nose depressed at base and the tendency of the frontal bones to fuse together and form an eminence of peculiar shape. But in respect to the character of the hair, the white man stands in closer relation to the higher apes than does the Negro.

Mental Qualities.—In reviewing the comparative studies of the differences between the Negro and the modern European, Carr-Sanders concludes that "there seems to be no marked difference in innate intellectual power. The differences are rather differences in disposition and temperament. . . . The apparent arrest of development may not be so much an inevitable result of the kind of mental faculties which are inherited as the coming into play of a peculiar tradition." (*Population Problem*, 1922, p. 397.)

It is not fair to judge of the Negro's mental capacity by tests taken directly from the environment of the white man, as for instance tests in mental arithmetic; skill in reckoning is necessary to the white race, and it has cultivated this faculty; but it is not necessary to the Negroes, who often surpass white men in acuteness of vision, hearing, sense of direction and topography. Given suitable training, the Negro is capable of becoming a craftsman of considerable skill, particularly in metal work, carpentry and carving. The bronze castings by the *cire perdue* process, and the cups and horns of ivory elaborately carved, which were produced by the natives of Guinea after their intercourse with the Portuguese of the 16th century, bear ample witness to this.

Social Conditions.—Generally speaking the Negro is first and foremost an agriculturist. Next in importance to agriculture come hunting and fishing and, locally, cattle-keeping. The last is not strictly typical of Negro culture at all; nearly all the tribes by whom it is practised are of mixed origin, except perhaps the Dinka of the upper Nile, the whole of whose existence centres round the cattle pen. The social conditions are usually primitive, especially among the Negroes proper, being based on the village community ruled by a chief. Where the country is open, or where the forest presents no great obstacle to communication, a chief has often extended his rule over several villages and has ultimately built up a kingdom administered by sub-chiefs of various grades, and has even established a court with a regular hierarchy of officials. This "empire-building" has reached its greatest proportions in the south of the forest belt in the territory of the Bantu Negroids, where arose the states of Lunda, Cazembe, etc.

The domestic life of the Negro is based upon polygyny, so vital an element of the native social system that attempts to abolish plurality of wives would result in the most serious social disorder. Descent in the Negro world is often reckoned through the female, though many tribes with a patriarchal system are found. Traces of totemism are found sporadically. Secret societies are found in their highest development among the Negroes of the west coast.

The Negro is principally a vegetarian. Meat is everywhere regarded as a great delicacy. The cattle-keeping tribes rarely slaughter for food, because cattle are a form of currency. Fish is also an important article of diet in the neighbourhood of large rivers, especially the Nile and Congo. The two cultivated plants which form the mainstay of native life, manioc in the west and centre and mealies in the south and east, are neither of African origin. Cannibalism (*q.v.*) is found in its simplest form in Africa, where the majority of cannibal tribes eat human flesh because they like it. Among the true Negroes it is confined mainly to the

Welle and Ubangi districts, though found sporadically (and due to magical motives) on the west coast, and among the Bantu Negroids in the south-western part of Belgian Congo and the Gabun.

The most important craft is that of iron smelting and working. A good deal of aptitude is shown in the forging of iron, despite the primitive tools. Considerable skill in carving is also found in the west and among the Bantu Negroids, especially of Belgian Congo south of the Congo. Weaving is practised to a large extent in the west; the true native material being palm-leaf fibre. The cultivation of cotton has become important in West Africa. Among the Bantu of the Kasai district the art of weaving palm-cloth reaches its highest level, and in the east cotton-weaving is again found. Pottery-making is almost universal, though nowhere very advanced; the wheel is unknown, though an appliance used on the lower Congo displays the principle in rudimentary form. The production of fire by friction was universal, the method known as "twirling" being in vogue, *i.e.*, the rapid rotation between the palms of a piece of hard wood upon a piece of soft wood.

Trading is practised either by direct barter or by rude forms of currency which vary according to locality. Value is reckoned among the tribes with pastoral tendencies in cattle and goats; among the eastern Negroes by hoe- and spear-blades and salt blocks; in the west by cowries, brass rods and bronze armlets (manilas); in Belgian Congo variously by *olivella* shells, brass rods, salt, goats and fowls, copper ingots and iron spear-blades, etc.

Religion.—In the western forests where communities are small the Negro is a fetishist, combined more or less with nature worship. Where communication is easier worship becomes more systematic, and definite supernatural agencies are recognized, presiding over definite spheres of human life. Ancestor-worship appears and often assumes paramount importance, and is typical of all the eastern and southern portions of the continent. Malignant powers receive attention from man, with a view to propitiation or coercion. Beneficent agencies require no attention, since, from their very nature, they must continue to do good. In the western culture area, among both Negro and Bantu Negroid tribes, is the belief that any form of death except by violence must be due to evil magic exercised by, or through the agency of, some human individual; to discover the guilty party the poison ordeal is freely used. Similar ordeals are used in British Central Africa to discover magicians, and the wholesale "smelling-out" of "witches," was well-known among the Zulu-Xosa tribes. Everywhere magic, both sympathetic and imitative, is practised, both by the ordinary individual and by professional magicians, and most medical treatment is based on this, although the magician is usually a herbalist of some skill. Where the rainfall is uncertain, the production of rain by magical means is one of the chief duties of the magician, a duty which becomes paramount in the eastern plains among Negroes and Bantu Negroids alike.

Negroes and Negroids have been considerably influenced by Mohammedanism along the whole extent of country bordering the Sahara and in the east. Islam is simple, categorical and easily comprehended; it does not upset the native social system, especially in the matter of polygyny, and discourages indulgence in drink. Moreover, the number of native missionaries is considerable, and they are nearer to the people than strangers.

The Bantu Negroids all speak dialects of one tongue (*see* BANTU LANGUAGES). The Sudanic family of languages is spoken in the area recognized as the habitat of the Negro, but Hamitic speech (Nilotic group) is also used by Negroes.

See the excellent bibliography in Africa I. 3. p. 240 sqq. (1928) by Henri Laburet for the most important modern works, and A. B. Ellis, The Tshi-speaking Peoples (1887); The Bwe-speaking Peoples (1890); The Yoruba-speaking Peoples (1894).

NEGRO, THE AMERICAN. The migration of the European fair-skinned races in large numbers to other parts of the earth occupied by people of darker colour created a whole series of problems in the adjustment of racial relations which were almost unknown to the ancient world or to the life of modern

Europe. These problems have been and are perhaps more acute in the United States than elsewhere, because there the lightest and the darkest races have commingled, because of the theory on which the government of the country nominally rests, that each freeman should be given an equal chance to improve his industrial position and an equal voice in deciding political questions, and because of the long-time almost irreconcilable differences in the public opinion of the two great sections of America. They were not solved by the Civil War and emancipation, but their nature was radically altered.

During the colonial period, and down to the changes initiated by the invention of the cotton gin, Negroes were distributed with some evenness along the Atlantic coast. Between the date of that invention and the Civil War, and largely as a result of the changes the cotton gin set in motion, the tendency was towards a concentration of the Negroes in the great cotton-growing area of the country. In 1700, for example, one-ninth of the population of the colony of New York was Negro; in 1900 only one-seventieth of the population of the Empire State belonged to that race. In the States north of Mason and Dixon's line, in all of which but Missouri Negro slavery either never existed or else was abolished before the Civil War, the white population increased tenfold and the Negro population only fourfold between 1790 and 1860. In the States south of that line, on the contrary, the southern States, the Negro population in the same period increased sixfold and the white population not so fast. It was a widespread opinion shortly after the Civil War that the emancipated slaves would speedily disperse through the country, and that this process would greatly simplify the problems arising from the contact of the two races. This expectation has not been entirely falsified by the result. Between 1860 and 1900 the Negroes in the northern States increased somewhat more rapidly than the northern whites, and those in the southern States much less rapidly than the southern whites. The five States with the greatest amount of Negro increase between 1900 and 1910 were all southern States. The increase in them was nearly one-half (49%) of that of the whole country. The five States which occupied a similar position between 1910 and 1920 were Pennsylvania, Ohio, Illinois, North Carolina and New York, four of them northern States, and the increase in them was nearly three-fifths (58%) of the whole. These four northern States are highly urbanised. The facts suggest a migration to industrial centres. The conjecture may be tested by computing the percentage of increase of urban population both Negro and white. From 1900 to 1910 the whites in cities having 2,500 inhabitants or more increased 39.1% and the Negroes 34.2%; from 1910 to 1920 the percentage of increase decreased for each race, but among the whites it fell 10.5% to 28.6%, and among Negroes it fell 1.6% to 32.6%, so that between 1910 and 1920 Negroes in cities increased at a higher rate than the whites.

The large amount of Negro migration to northern cities between 1910 and 1920 and the comparatively slight migration in 1900-19 appear from the following table:—

City	Negro population in 1900	Increase of Negroes	
		1900-10	1910-20
Chicago	30,150	13,953	65,355
New York	60,666	31,043	60,758
Philadelphia	62,616	21,846	49,770
Detroit	4,111	1,630	35,097
Cleveland	5,988	2,460	26,003
St. Louis	35,516	8,444	25,894
Total	199,047	79,376	262,877

The preceding figures are for the cities in which the Negro population increased by 25,000 or more between 1910 and 1920. All lie outside of the southern States. The Negro population of these six cities increased between 1900 and 1910 by 39%, and between 1910 and 1920 by 95%. As the increase of Negroes in all northern States between 1910 and 1920 was 444,635, nearly three-fifths (59%) of that increase was in these six cities.

The question "Have the American Negroes progressed, ma-

terially and morally, since emancipation?" is generally answered in the affirmative. But even on this question entire unanimity is lacking. Probably all competent students would admit, however, that the race has differentiated since 1865.

Evidence with regard to the progress of the American Negro is set forth under the following heads: numbers, showing ratio of Negro per cent of increase to White population; births and deaths, showing natural increase or decrease of Negroes by States; health, morals, and citizenship.

Numbers.—The Negro population of the United States as enumerated in 1920 was 10,463,131, an increase of 635,368, or 6.5% over 1910. The rate of increase was less than in any preceding decade and less than three-fifths of that between 1900 and 1910, the smallest up to that time. As in the white population the rate of increase between 1910 and 1920 was less than in any preceding decade. It might be thought that the fall in the increase among Negroes conformed to the trend of population change, but this would be an error. The rate of increase of Negroes in 1900-10 was about .5 and in 1910-20 about .4 of that of the whites. That this deviation in the rates of increase had been maintained for a long period appears from the following figures:—

Period	Increase				Ratio of Negro per cent of increase to White (100)
	Amount in thousands		Per cent		
	Negro	White	Negro	White	
1800-20	770	3,560	76.8	82.7	93
1820-40	1,102	6,329	62.2	80.5	77
1840-60	1,568	12,727	54.6	80.7	61
1860-80	2,139	16,481	48.2	61.2	79
1880-1900	2,253	23,280	34.2	53.9	64
1900-20	1,620	28,012	18.4	41.9	44

The numerical increase of Negroes was larger in the later periods, rising to a maximum in the last 20 years of the 19th century. The rate of increase, on the contrary, diminished steadily. At each period the rate of Negro increase was less than that of the white. Apparently the immediate result of the Civil War and emancipation was to raise the relative rate of Negro increase between 1860 and 1880 from .6 to nearly .8 of that of the whites. But since 1880 the rate of Negro increase has fallen rapidly, and Negroes, who in 1800 were 18.9% of the country's population, in 1920 were only 9.9%. If each race should increase through the present century as it did between 1900 and 1920, the population of the country in A.D. 2000 would be over 400,000,000, of which about 20,000,000, or one-twentieth, would be Negro. The rate of increase of each race is likely to fall, but the difference in favour of the white race is not likely to diminish.

Births and Deaths.—The remarkable fall in the rate of Negro increase and the rapid distribution of Negroes to other parts of the country than the South, especially to certain northern cities, are the striking changes revealed by the fourteenth census. How is the fall in the rate of increase to be explained? Has it any connection with the growth of interstate migration? These questions are elucidated by turning from the census figures of living population to the registration figures of births and deaths. The following tables show the registered births and deaths of Negroes in each of 30 States arranged in the order of increasing proportion of deaths to births.

If Negro deaths had exceeded births in the 17 states of the last table between 1910 and 1920, and if there had been no immigration of Negroes to this group of states, the number of resident Negroes would have been less in 1920 than in 1910. In fact, it increased from 352,120 to 1,113,940 or 30.7%. The total immigration to these States for the decade was probably not less than 300,000.

There are seven southern States for which we have births and deaths reported, and all but Kentucky had an excess of births over deaths. The Negro population of these States increased between 1910 and 1920 about 1%. On the basis of the figures for 1919 and 1920 there was a natural increase of about 35,600 annually,

States with a Natural Increase of Negroes

State	Period covered by registration	Negro births	Negro deaths	Deaths to 100 births
North Carolina	1917-22	143,367	77,758	54
Mississippi	1921-22	44,940	24,574	55
South Carolina	1919-22	65,110	53,172	56
Virginia	1917-22	110,435	77,775	65
New Jersey	1921-22	6,770	4,771	70
Maryland	1910-22	45,871	40,245	87
Massachusetts	1915-22	8,840	7,870	89
Wisconsin	1917-22	657	597	91
New York	1915-22	34,502	32,126	93
Delaware	1921-22	1,248	1,200	96
Michigan	1915-22	7,003	7,453	98
Connecticut	1915-22	3,800	3,808	99
New Hampshire	1915-22	86	85	99
Total		512,334	331,694	65

States with a Natural Decrease of Negroes

State	Period covered by registration	Negro births	Negro deaths	Deaths to 100 births
Illinois	1922	3,704	3,786	102
Pennsylvania	1915-22	45,311	48,207	106
Ohio	1917-22	21,710	23,940	110
Rhode Island	1915-19 and 1921-22	1,522	1,684	111
California	1910-22	2,688	3,054	114
Indiana	1917-22	8,758	10,377	119
Nebraska	1920-22	564	685	122
Kansas	1917-22	5,956	7,286	122
Utah	1917-22	128	158	123
Kentucky	1917-22	24,180	30,343	125
Vermont	1915-22	20	38	131
Oregon	1910-22	100	154	150
Minnesota	1915-22	913	1,388	152
Washington	1917-22	424	738	174
Montana	1922	20	40	200
Wyoming	1922	17	39	229
Maine	1915-22	84	194	231
Total		116,117	132,111	114

or 356,000 for the decade. As the decennial increase of Negroes was about 40,000, these States must have lost by emigration more than 300,000.

The bureau of the census has supplied figures of Negro births and deaths between 1915 and 1923 in the urban and rural districts. They are as follows:—

	Births	Deaths	Deaths to 100 births
Urban	266,380	269,631	102
Rural	517,945	309,243	60

These show that during these eight years in the cities of the United States for which the facts are known there were 3,251 more Negro deaths than births, but that in the country districts there were 208,702 more births than deaths. The figures of each class are given separately below for North and South.

	Births	Deaths	Deaths to 100 births
Northern urban	155,972	151,118	97
Northern rural	33,245	40,294	121
Northern total	189,217	191,412	101
Southern urban	110,408	118,513	107
Southern rural	484,700	268,949	55
Southern total	595,108	387,462	68

These figures show that the rural districts of the North are least suitable for Negro increase, that the urban districts of the South are almost as unfavourable, that the cities of the North show a slight excess of Negro births, and that the great reservoir for Negro increase is the rural districts of the South. The cause for the low rate of increase between 1910 and 1920 is found in the

migration from the country districts of the South both to the North and to southern cities, and to their exposure to conditions climatic or economic which raised the death-rate and lowered the birth-rate.

Health.—The prosperity and progress of a population group are indicated, not merely by growth in numbers but also by the longevity of its members. This vitality is roughly measured by the death-rate. Other things being equal, a low and sinking death-rate is evidence of a high and increasing average duration of life. In the United States vital statistics are in charge of the several States and cities, and are often defective or entirely lacking. In 1890 and 1900 the Federal government compiled such as were of importance, and in 1864 an official compilation was made of death-rates of Negroes before the war. The 1910 and 1924 figures are based on population in the 1910 and 1924 registration areas, respectively. Southern States have been the slowest to perfect their registry sufficiently to gain admission to the registered area and in 1910 but 19.7% of the Negroes lived in the registration area. In 1924 all southern States but West Virginia, Alabama, Arkansas, Oklahoma and Texas were included in the area so that the figures are much more complete. Part of the rapid decrease in Negro mortality may be due to the fact that the registration area is extending over more and more of southern rural territory where the Negro death rate is much lower.

Date	Negro deaths	Negro death-rate	White death-rate
Mainly between			
1818-63 . . .	106,217	35.0	27.0
1890	28,579	29.9	19.1
1900	37,020	29.6	17.3
1910	49,499	25.5	14.6
1924	147,852	17.6	11.2

These figures indicate that the death-rate of each race decreased during a half century, but that the decrease among Negroes was less rapid than among whites.

Morals.—Though its shortcomings are immediately apparent, obedience to law is the only practical index available for judging the comparative moral health of the Negro race in the United States. Reliance on statistics of prisoners instead of true judicial statistics offers plenty of opportunity for further qualifications. The Negroes are rarely able to employ expert defense, and many of the classes which come to trial are too ignorant to understand intelligently their own cases and situations. That prison punishment is more severe for Negroes than for whites, seems apparent from the fact that the 1910 census showed the average sentence of the Negro to be 17.4 months while that of the white was 5.2 months. It is doubtful if the wide difference between the two can be due entirely to the degree of the Negro's crime. In 1910 and 1923 prison statistics included prisoners awaiting trial and those imprisoned for failing to pay a fine. The Negro forms a large proportion of these classes for he does not often have the amount necessary to cover the bail or fine. This fact must be taken into consideration in comparing the number of prisoners in the table given below:

Date	Negro prisoners		White prisoners per 100,000 pop.
	Number	Per 100,000 pop.	
1880	16,089	244	96
1890	10,804	264	84
1904	20,087	278	77
1910	38,701	384	89
1923	34,178	327	77

Whether the sharp increase between 1904 and 1910 was due entirely to the factors mentioned above or partially to increased crime it is impossible to say. In any case there was a marked decrease between 1910 and 1923. The proportion of Negro prisoners among all prisoners in the United States declined in this period from 34.0% to 31.3% despite the increase in Negro population. Some factors accounting for the higher percentage of crime among Negroes are (1) a greater degree of illiteracy,

(2) crowded, unhealthy and even vicious living conditions in many cities, (3) poverty in both cities and rural districts, and (4) inadequate provision for the segregation of feeble-minded and mentally unbalanced Negroes in many communities. Whether in the final analysis there is, in addition, a greater tendency toward crime inherent in the Negro race is a question upon which there is great difference of opinion and little scientific data.

In considering the offenses for which prison terms were imposed in 1923 Negroes formed exceptionally high percentages of the totals convicted of gambling (64%), carrying concealed weapons (51.4%), assault (43.9%), fornication and prostitution (43.7%) and homicide (41.5%). For rape, despite a wide belief that the Negro is particularly prone to this crime, Negro commitments were but 17.8% of the total for this cause, which was considerably below the proportion for either native or foreign-born whites.

The proportion of commitments of Negroes to their population was much lower in the southern States than in either the northern or western States, which condition is probably due chiefly to the fact that in the South greater numbers of the Negroes live in rural districts while in the North or West they are congregated in cities and towns where higher commitment rates are to be expected. Such figures also suggest lack of adjustment to their surroundings resulting from their migrations of recent years.

Citizenship.—When the Fourteenth and Fifteenth Amendments to the Federal Constitution were adopted, the former conferring United States citizenship on all native Negroes and the latter providing that the right of such citizens to vote should not be abridged by any State on account of race, colour or previous condition of servitude, it was not the practice in northern States to allow Negroes to vote. Proposals to grant them the suffrage were submitted to the voters in 1865 in Connecticut, Wisconsin, Minnesota and Colorado, and in each State they were rejected. In all States containing a large proportion of Negroes, the results of the Federal policy of reconstruction were disastrous. Since the withdrawal of Federal troops in 1877 the prevailing and persistent judgment of southern whites regarding the laws and the policy to be adopted upon this subject has been accorded more and more weight in determining the action of the States and the Federal Government. The number of Negroes voting or entitled to vote has been reduced latterly by legislation or provisions of the State Constitutions. If such enactments are nominally directed not against any race but against certain characteristics which may appear mainly in the race, such as illiteracy, inability or unwillingness to pay an annual poll tax or to register each year, they have been and are likely to be held within the constitutional authority of the State. On the part of the overwhelming majority of Negroes this practical disfranchisement has aroused little protest, while it has tended to improve the government and to open the way for the gradual development and expression in word and vote of differences within the ranks of white voters regarding questions of public policy.

Along with this decrease of pressure from without the southern States and the development of economic competition between the races within them, there has gone an increased demand on the part of the whites for a complete social separation between the races in school, in church, in public conveyances and hotels, all founded upon a fear that any disregard of such separateness will make intermarriage or fruitful illegal unions between the races more frequent. In short, these developments are towards a more and more rigid caste system.

NEGRO ECONOMIC LIFE

Following emancipation, in 1865, the large majority of Negroes gainfully employed were in agriculture. In 1890 there were 1,362,713 Negro agricultural labourers; in 1920, 1,192,504. In 1910 more than one-fourth of the Negro female population ten years of age and over were employed in agriculture. By thrift and hard labour the land-owning Negro farmer has arisen. Of 746,717 Negro farmers in 1900, 25.1% were owners, 0.2% managers and 74.6% tenants; in 1920, of 925,708 Negro farmers, 23.5% were owners, 0.2% managers and 76.3% tenants. The value of land and buildings owned by Negro farmers in the Southern States was \$69,634,420 in 1900, and \$552,178,137 in 1920.

Industrial Workers and Artisans.—Between 1850-60 there were cases of slaves manning cotton factories and working successfully in iron mines, furnaces and tobacco factories. The post-war development of the southern cotton mills, however, turned to white labour. The slave artisan became an important factor in the *ante-bellum* economic organization of the South. Even before the Revolutionary War Negro slaves were employed in New Jersey as iron workers, sawmill hands, wheelwrights, tanners, coopers, shoemakers, etc., and as early as 1708 white mechanics felt the competition of slaves in Pennsylvania. Employment in the North was mainly in semi-skilled and unskilled occupations, Negroes following the prevailing occupations of the locality; barbers, bakers, carpenters, clothiers, domestics, hairdressers, labourers, seamen, and waiters. There were a few physicians, clergymen, merchants and traders and saloon and restaurant keepers. As late as 1908-10, a study of Negroes at work in New York city found over 70% of the men and 89% of the women gainfully employed in domestic and personal service.

In 1900, there were in the United States 275,149 Negroes in manufacturing and mechanical pursuits, or 6.9% of those gainfully employed, and 209,154 in trade and transportation (5.2%); by 1920 there were 960,039 in manufacturing and mechanical pursuits (19.9%) and 540,451 in trade and transportation (11.2%).

In 1920 about 73.4% of the Negro population of the northern States was living in ten industrial districts where immigrant labour had largely supplied the surplus of workers prior to 1914.

In the South wages paid Negroes are generally somewhat less than those paid whites in the same occupations. In the North industrial wages are about the same for occupations to which Negroes are admitted. Negro workers are handicapped in both sections, however, by restrictions on promotion to higher jobs, by greater difficulty in obtaining employment by exclusion from unions and by less security of tenure. In the building trades and some other fields increasing numbers of Negroes have been admitted to unions and are thus overcoming these barriers.

The Professional Class.—In 1920 there were 19,571 Negro clergymen. Before the Civil War there were Negro teachers who conducted private schools in the North and in the South for children of free Negroes. Law and custom forbade teaching slaves. With freedom, the greatest outreach of Negroes was for education, and teachers' increased accordingly. There were 29,727 Negro teachers, professors and college presidents in 1910 and 36,626 in 1920.

In 1860 there were 14 physicians and a Negro dentist in Massachusetts; five dentists in Philadelphia and one physician in St. Louis. The number of Negro physicians, surgeons and dentists had increased to 3,555 in 1910 and to 4,819 in 1920. There were 41,324 Negroes in professional service in 1900, and 80,183

in 1920. The proportion in professional service of all Negroes gainfully employed, however, remained the same, 3.7%.

Trade and Commerce.—*The Negro Year Book* estimates that there were 4,000 Negroes in business in 1866. These were usually small enterprises such as those of blacksmiths, shoemakers, barbers, tailors, caterers and hotel keepers. Here and there Negroes of marked ability developed enterprises of proportions before 1860. There were a few foundries, rope and cordage factories, drygoods and grocery stores and similar establishments. The intervening decades show slow but substantial growth. There were over 50,000 Negro business establishments in 1920 and about 70,000 in 1926.

Life insurance among Negroes has grown rapidly in 20 years and is now the largest business owned and operated by them. The first old line, legal reserve Negro life insurance company was organized in 1912. There were already several industrial life companies, and several white companies were carrying Negro risks. In 1926, there were 23 Negro companies, with business in force amounting to \$243,534,500, of which \$96,064,700 was old line, legal reserve, \$97,018,263 industrial and \$50,451,537 sick and accident insurance; and employing 9,100 Negroes as officers, agents and clerical force; their net income for the year of \$1,509,467 and their gross assets of \$11,170,191 represent financial resources within the Group. Fire insurance has been of recent development. The first stock company was organized in Georgia in 1919 and was merged in 1922 with the only Negro fire insurance company now existing. In 1926 this company had \$200,800 capital, \$43,156 surplus and \$371,590 total assets.

In 1926 there were about 33 savings and commercial banks exclusively of the standard stock type. There are probably between 30 and 50 building and loan associations, mutual savings and savings and loan or investment associations owned and operated by Negroes.

Property Ownership.—In 1920 in five northern cities Negroes owned from 27% to 41.9% of the homes they occupied and in nine southern cities, from 20.2% to 40.4%. Of the 488,699 Negro homes owned in 1910, there were 346,867 reported free of encumbrance and 123,044 encumbered, and 18,788 unknown.

NEGRO EDUCATION

Prior to the emancipation of Negroes in the United States in 1865 there were isolated instances in both the North and South of the establishment of schools for free Negroes. Negligible effects attended these efforts, however, because of opposition in the North and legislative enactments in the South forbidding the education of Negroes enslaved or free. Despite these barriers, a few Negroes entered northern white academies and universities and some graduated. Any discussion, however, of Negro education in America must begin substantially with the adoption of the reconstruction Constitutions by the former slave States.

Social factors not considered, mixed schools would have been the most economical and effective educational instrument and probably were the only means of insuring equal education for the two races. Several States considered the idea more or less seriously and for a short period South Carolina adopted it. But certain political, social and biological theories concerning the race

placed the Negro at the bottom of the social scale, and tended to restrict the amount, quality and kind of education considered assimilable by the Negro and necessary to fit him for the place assigned him in the social structure.

The extreme biological theory assumed the Negro incapable of education; the extreme social attitude held that education "spoiled" the Negro for useful pursuits; while the liberal attitude is expressed by these words in the doorway of a Negro school in Alabama: "It is the duty of the South to train the descendants of the former slaves to become intelligent, productive, industrial units in the commonwealth." The Negroes bitterly resented these restrictions and their feelings were shared to a considerable degree by many white people interested in Negro education. Private schools for Negroes sprang up all over the South, supported largely by northern philanthropy and conducted by northern white educational missionaries, though many were maintained by Negroes. These schools supplied most of their secondary education and practically all of their collegiate training.

About 1905 a general educational revival began in the South with a new emphasis on education for both races. The Negro had proved his capacity for education. Increasing industrial prosperity in the South and the lessening of isolation effected a general willingness to provide more liberally out of public taxation for Negro education. Since 1915 this tendency has grown steadily. The National Association of Teachers in Colored Schools organized in 1903 and the State associations of Negro teachers have done much to stimulate more liberal public sentiment. Negro college attendance has increased 150% in 1923-28, showing how Negroes have reacted to increased facilities for education.

NEGRO ART

Negro art, in the broader sense, may be said to include work portraying Negro life by other than Negro artists; in a narrower sense, to include all the work of Negro artists. The Negro himself, though possessing a strong African heritage in craft and decorative art, was hampered in his expression in the field of the formal arts by the conditions of the slave system, and the sudden displacement by Christianity of the pagan background in which the original African arts flourished. However, in favourable centres like Philadelphia, Charleston and New Orleans, craft artisans of exceptional skill in wood and ironwork flourished until the breakdown between 1840-50 of craft skill by the factory system. Of these the most famous were the Negro art-smiths of New Orleans.

In formal painting, the pioneer Negro artist was Edward Bannister (Providence, R.I.), a landscape-painter, prize winner at the Centennial Exposition at Philadelphia (1876) and founder of the Providence Art club. At the same exhibition, Edmonia Lewis, pioneer sculptor, exhibited her busts of William Story, Charles Sumner and Frederick Douglass. Other early Negro artists between 1865 and 1885 were Edward Stidham (Philadelphia), portraitist; William Dorsey (Philadelphia), landscape-painter; and Robert Duncanson (Cincinnati), figure-painter.

These were followed, after a dead interval, by the two Negro artists who have achieved rank in American painting and sculpture, Henry Ossawa Tanner and Meta Warrick Fuller. Tanner's painting, mostly of biblical subjects, in addition to the romantic realism of his French masters, reflects the mysticism and literal faith of his Negro parentage and, like the work of the Israels, combines utmost sophistication of technique with naive simplicity of theme. His technical skill is attested by many prize awards and also by his inclusion in the Luxembourg, Wilstach, Pennsylvania Academy of Fine Arts, Carnegie Institute, Chicago Art Institute and other collections. A school of formal academic painting has followed Tanner: William Harper (1874-1910), landscape painter of note; William Edouard Scott (b. 1884), portraitist and mural painter; William Farrow (b. 1885), landscapist and etcher;

Charles Dawson (b. 1889), portrait painter and engraver; Edward A. Harleston (b. 1890), portraitist and figure painter of merit; and Laura Wheeler Waring (b. 1887), type portraitist and decorative illustrator.

In sculpture, the outstanding Negro has been Meta Warrick Fuller (b. 1877), educated at the Pennsylvania School of Industrial Art, and pupil of Colarossi academy, St. Gaudens and Rodin. She achieved recognition in the Paris salons of 1903 and 1904 with her forceful symbolic works,—"Oedipus," "Secret Sorrow," "The Wretched," "The Impenitent Thief" and "John the Baptist." Later she turned to the delineation of Afro-American types with her series of 14 groups representing the history and progress of the Negro, for the Jamestown Exposition (1907) and her "Ethiopia Unbound," executed for the New York Emancipation Semi-Centennial (1913). Later still she turned to portrait sculpture and to abstract symbolic groups. In similar vein but with slightly more attention to racial types, May Howard Jackson (b. 1878) has done meritorious work in sculpture. Though occasionally racial in subject and reflecting somewhat the peculiar emotional background of the Negro, the work of all the foregoing artists has been traditional in ambition, sympathy and technique, and success and recognition have come to them primarily as artists.

The younger Negro artists since 1920 have broken somewhat with academic tradition and there has emerged a school of Negro art along distinctive and original lines devoted consciously to racial portrayal and expression. Activity has mainly focused in a New York or Harlem group, among whom the more outstanding are Palmer Hayden (landscapist), Aaron Douglas (figure painter and illustrator), M. Gray Johnson, W. J. Russell, Albert Smith (painter and etcher), Augusta Savage (sculptor) and a Chicago group among whom the better known are Archibald J. Motley, Hale Woodruff, John Hardrick, Arthur Diggs, painters; and Sargent Johnson and Richmond Barthé, sculptors. The most promising and modernist trend is represented by a series of paintings by Archibald Motley symbolizing the African background and the use of African motifs in the decorative drawings and illustrations of Aaron Douglas.

NEGRO DRAMA

Negro drama as found in the United States represents the same tendency toward the development of race or group drama as is to be found elsewhere. It exemplifies the development of a group consciousness and the consequent urge for artistic expression of a people possessing a common tradition and race experience. Negro drama is likewise a recognized phase of American drama.

In the period previous to the Civil War the Negro appeared as a minor character in L. Beach's *Post Free* (1807) and in Anna Cora Mowatt's *Fashion* (1845). In the '40s the minstrel show was making its appearance. Charles Callender, Lew Dockstader and Primrose and West, in turn presented caricatures of the Negro that have persisted in the American theatre. Following the Civil War the novel by Harriet Beecher Stowe, *Uncle Tom's Cabin*, was dramatized and produced throughout the North, soon to be followed by another drama of the same type, *The Octoroon*, by Dion Boucicault. These plays accustomed the public to Negro drama designed to appeal to its sympathy rather than its ridicule. The minstrel characterization of the Negro continued until 1895, when John W. Isham organized a musical show, *The Octoroons*, the first of a long line of musical comedies which have opened the doors of opportunity to a group of notable Negro actors, including Williams and Walker, Cole and Johnson, S. H. Dudley, T. Leubie Hill, Ernest Hogan, Sissle and Blake, Miller and Lyles, Florence Mills and Adelaide Hall. These musical shows have contributed little to the direct stream of Negro drama, yet they have demonstrated the exceptional histrionic talents of the race. They may yet furnish the material for the evolution of new dramatic forms in the future. Witness the interesting experiment of Lawrence Stallings and Frank Harland in the jazz opera *Deep River* and Edna Ferber in *Show Boat*.

In 1910, Edward Sheldon's *The Nigger* was produced. In 1913 W. E. B. Du Bois wrote and produced the first important Negro pageant, *The Star of Ethiopia*. On March 3, 1916, *Rachel*, a three-act play written by Angelica Grimke and the first successful drama written by a Negro, was produced.

The first important step in the development of an authentic Negro drama was taken on April 5, 1917, when Mrs. Norman Hapgood, in association with Robert Edmond Jones and others, presented a group of Negro actors in a programme of three one-act plays written for the Negro theatre by the American poet, Ridgely Torrence.

In the years immediately following the termination of the World War Negro drama suddenly assumed a place of major importance in American drama. The production of Eugene O'Neill's, *The Emperor Jones*, proved to be a landmark. Charles Gilpin, a Negro, who played the title rôle of the emperor, was selected by the New York Drama League as one of the ten persons who had contributed the most to the American theatre during that year.

The Colored Folk theatre, later known as the Ethiopian Art theatre, was organized by Raymond O'Neill in co-operation with Mrs. Sherwood Anderson, in Chicago in 1923. Its main contribution to Negro drama was the excellent presentation of a one-act folk play, *The Chip Woman's Fortune*, written by a Negro playwright, Willis Richardson, who has contributed a number of meritorious one-act plays to Negro drama.

Simultaneously with the activities of these Little theatre groups a definite movement for the establishment of an experimental laboratory of Negro drama and for the development of a national Negro theatre was instituted at Howard university, a Negro university in Washington. The organizer and director of this undertaking was Montgomery Gregory, who was ably assisted by Alain Locke, Marie Moore Forrest, Cleon Throckmorton and the university authorities. Their leading idea was that the medium of dramatic expression offered the Negro race its best means of raising itself in the estimate of the American people. The Howard players successfully produced several one-act plays written by members of the group. Hampton institute, Tuskegee institute and Atlanta university are other Negro schools that have done effective work in educational and experimental race drama.

The Carolina playwrights of the University of North Carolina, under the inspired direction of Frederick Koch, have made notable contributions to Negro drama. Prof. Paul Green of this university ranks with Eugene O'Neill as the leading dramatist of Negro life. *White Dresses*, *Granny Boling*, *The No 'Count Boy*, *In the Valley* and the Pulitzer prize play, *In Abraham's Bosom*, are among his successful dramas. The awakened national interest in Negro drama chiefly occasioned by the production of *The Emperor Jones* has resulted in a succession of plays of Negro life on the New York stage. Some of these plays were: *Goat Alley* by E. Howard Culbertson, *Roseanne* by N. Stephens, *Taboo*, by Mary Hoyt Wiborg, *All God's Chillun Got Wings*, by Eugene O'Neill, *Black Boy*, by Jim Tully and Frank Dazy, *In the Bottom of the Cup*, by J. E. M. Bashe and *Porgy*, by Du Bose Heyward.

NEGRO MUSIC

American Negro music consists almost entirely of folk-music, the proportion of it written by individual composers being comparatively small. This music is of many kinds but it may be divided into two general classifications, sacred and secular. The sacred music consists of the well known Spirituals, while the secular is work, play and love songs, the blues and dance music—ragtime and jazz. The great bulk consists of songs; ragtime and jazz, however, are instrumental as well as vocal.

The Spirituals rank first in value and beauty. They, indeed, constitute one of the finest bodies of folk songs in the world. Just how far back the making of Spirituals by the Negro in America goes cannot be exactly determined, but it is safe to say more than

150 years. It is probable that he began creating these songs shortly after his adoption of Christianity, which came quite early, and along with the establishment of his own separate places of worship.

The Spirituals are primarily a fusion of African music and Christian sentiments. They possess the fundamental characteristics of African music; they have the same strong rhythmic quality and show a marked similarity to African songs in verse forms and intervallic structure. However, the Spirituals, upon the base of the primitive rhythms, rise a step beyond African music through a higher melodic and an added harmonic development. The Spirituals remain distinctive Negro folk-songs.

The texts of the Spirituals are based almost exclusively upon the Bible. The stories in the Bible gave the Negro bards great scope for the play of their imagination and are often told dramatically and in vivid and gorgeously coloured pictures.

It is probable that many of these songs are irretrievably lost, for no systematic effort to record them was made before the Civil War. They were first introduced to the public of America and Europe in 1871 by the Fisk Jubilee singers. They have recently been given a new vogue through the singing of them by Roland Hayes, Paul Robeson, J. Rosamond Johnson, Taylor Gordon and other Negro singers on the concert stage.

Negro secular music, unlike the Spirituals, has gone through many changes and developments. Most of the various styles of Negro secular music have successively been taken over, adapted and made national. And so it appears that as one style of the Negro's secular music became lost to him he set about creating another. Before and for a while after the Civil War the Negro made many plantation songs both of the ballad and the patter type. The plantation songs became the mainstay of the black-face minstrel stage; they were adapted and imitated and remained popular for several decades.

In the last decade of the past century ragtime, a highly syncopated form of music, came into notice. It is fundamentally an instrumental form, and was the result of experiments by Negro players on the piano—then a new instrument to them. Words were adapted to these syncopated rhythms and gave birth to the ragtime song, which achieved great popularity in the first decade or so of the present century. The Negro dialect text of the ragtime song was ultimately discarded for straight English, and this form of Negro music took on a national character, and so remains.

About 1910 a distinctly new type, the blues, was invented in the South and rapidly spread over the country. They are as truly folk-songs as the Spirituals; basic differences being that they are an expression of the individual and not of the group, and that they follow a rigid verse form and are less varied and rich than the Spirituals. This "blue" note has become one of the main elements of American popular music and has been experimented with by serious composers. (See BLUES.) Jazz (q.v.) is somewhat a combination and culmination of ragtime and the blues.

Another class of Negro folk-songs are the work-songs. These were originated by gangs of men at work which permitted of or called for rhythmic motions performed in unison; the picks or the hammers rising, falling and resting in perfect rhythm with the music.

Outstanding among individual Negro composers of note was James Bland who wrote *Carry Me back to Old Virginia* and *In The Evening by The Moonlight*, two songs which have attained a semi-classic niche. Other composers of note are: Harry T. Burleigh, J. Rosamond Johnson, R. Nathaniel Dett, Will Marion Cook, James P. Johnson, William Edward Still and Clarence Cameron White.

Johnson, *The Negro and His Songs* (Chapel Hill, 1925) and *Negro Workday Songs* (Chapel Hill, 1926).

See BLUES and JAZZ.

NEGRO POETRY

As early as the year 1760 Jupiter Hammon, a slave belonging to a Mr. Lloyd of Queens village, Long Island, N.Y., published a poem 88 lines in length, entitled *An Evening Thought, Salvation by Christ, with Penitential Cries*. Hammon published several other poems, all of them religious. However, it is with Phillis Wheatley (c. 1753-84), a young slave, that American Negro poetry properly begins.

Between Phillis Wheatley and Paul Laurence Dunbar there were about 30 Negroes who published poetry, the publications ranging in size from pamphlets to books of from 100 to 300 pages. These writers must be considered more in the light of what they attempted than of what they accomplished. A number of them showed marked talent and feeling, but barely a half-dozen demonstrated more than mediocre mastery of technique. Such were George Horton (1797-1880), Frances E. Harper (1825-1911), Charles Reason (b. 1818), James Madison Bell (b. 1826) and Alberry Whitman (b. 1857).

Paul Laurence Dunbar (1872-1906) (q.v.) was the first American Negro poet to show real poetic talent. Contemporary Negro poets were: James Edwin Campbell, Daniel Webster Davis, George M. McClellan, J. Mord Allen, James D. Corrothers, William H. A. Moore and Joseph S. Cotter, sr.

The decade after the death of Dunbar was fallow, but William Stanley Braithwaite (b. 1878) achieved recognition as a poet, critic and anthologist. His work, however, is not in subject-matter or form related to race. In general, his poems are mystic in tone.

Immediately after the entry of the United States into the World War (1917) there emerged a group of poets who almost completely discarded dialect and the traditional material of Negro poetry, including pathos and humour. The distinguishing notes of their poetry were disillusionment, protest and challenge. In this group were Claude McKay, Fenton Johnson, Joseph Cotter, jr., Georgia Douglas Johnson, Roscoe Jamison, Lucien Watkins and James Weldon Johnson. It was in Claude McKay (b. 1890) that this period of protest found its most powerful voice.

A half-dozen years after the beginning of the period of protest, American Negro poetry began discarding propaganda for propaganda's sake, and essayed a more purely artistic use of racial art material and cultural background. Two new poets arose in this latest period. They were Countee Cullen (b. 1903) and Langston Hughes (b. 1902). Cullen is a poet of lyrical power and beauty. He writes only in the well approved forms of literary English, but many of his best poems contain a racial note of deep poignancy. In 1925 he published his first volume, *Color*; this was followed in 1927 by *The Ballad of the Brown Girl* and *Copper Sun*. Hughes is more the folk poet in the selection of subject-matter and forms. Much of his material is taken from the humbler strata of life, and he has made effective use of the form of the Blues (see *Music*, p. 219). He is the author of *The Weary Blues* (1926) and *Fine Clothes to the Jew* (1927). In this period James Weldon Johnson published *God's Trombones—Seven Negro Sermons in Verse* (1927), founded on the old-time Negro plantation sermons. In the group of newer Negro poets writing distinctive verse are: Jean Toomer, Anne Spencer, Arna Bontemps, Angelina Grimke, Lewis Alexander, Jessie Fauset, Sterling Brown, Helene Johnson and Waring Cuney.

NEGRO FOLKLORE

The folk-lore of the Negro of the United States, for all its surface appearance of naïve simplicity, is a complex thing. Its origins are mixed, and often lost in obscurity. Some elements are clearly African in their beginnings, while others are as definitely related to the lore of the whites. The "big house" of colonial days, as well as the jungle of Africa has had its share in shaping Negro

folk-lore. The transplanted race cherishes the superstitions, the ballads, the stories of both the new home and the old, and what it borrows makes its own as distinctly as what it originated.

There is a rich body of folk-tales current among the American Negroes, some of which have been preserved in print, and many of which are transmitted orally by the firesides and door-steps of the south. A still greater mass, no doubt, has been lost for lack of chroniclers and tellers. The best-known body of their published folk-tales is that collected by Joel Chandler Harris—made familiar by the name of Uncle Remus.

In his songs and stories the Negro shows his fondness for animals, his admiration for their craft, his interest in their prowess. He endows them with human attributes of thought and speech, and gives them greater cunning than natural history would authorize.

The Negro shows great variety in his songs, contrary to the popular conception that he sings only spirituals. The spirituals, which are melodious and haunting in their tunes, and which express humility and sweetness of spirit, owe something at least to the hymns and religious songs heard on the southern plantation. There are various groups of secular songs. There are numerous work songs, for the Negro, a truly rhythmic person, works better and faster when he sings at his task.

The American Negro has had his part in transmitting the traditional songs and ballads of England and Scotland, and has made them his own.

There are many ballads that the Negro has made for himself, owing nothing to the whites. There are lullabies, old dance songs or "reels," children's game songs, counting songs, songs of love, of war and of other themes.

There is a mass of folk-beliefs, of superstitions, current among the southern Negroes, belief in ghosts, in witches, in the power of "voodoo" and so forth. In fact, the Negro folk-lore constitutes the largest and most varied body of lore to be found in America to-day. (D. Sc.)

HARLEM

Harlem was originally a village on Manhattan island, now the local name for that part of the borough of Manhattan, New York city, beginning at 106th street and extending north between the East and Harlem rivers and Eighth avenue. Its settlement, on the site of what is now Mount Morris park, dates from 1636. In 1658 Peter Stuyvesant named the village New Haarlem, after Haarlem, the town in Holland from which many of its inhabitants came. The old village is charmingly described by Washington Irving in his *Knickerbocker's History of New York*. Harlem retained its quiet aspect, surrounded by farms, until 1836, when daily communication by horse railroad was established with New York. Thereafter, by degrees, the village became a populous suburb and was finally transformed into a densely built residential section of the metropolis. The name now refers more specifically to the district north of 125th street, which in the 1920's became the most populous urban Negro community in the world.

The Negro Metropolis.—During the World War about 500,000 Negroes, taking advantage of the restrictions placed upon European immigration, and lured by war-time wages, turned from agricultural pursuits in the South to the highly specialized industries of the North. In New York city the migrants, uniting their fortunes with a stream of 60,000 Negroes coming from Central America and the West Indies, swept uptown and formed above 125th street a fabulous Negro city of 250,000 souls. This district does not constitute, however, the only point of Negro mass contact on Manhattan island. On the crest of "San Juan Hill" is a colony of 5,000 to 6,000 Negroes which in point of primitivity and hardihood easily outstrips Harlem. Within the shadow of the Fifty-third street elevated are the remnants of a Negro settlement which antedates by at least a quarter of a century the glamorous "Mecca of the New Negro." But the concentration of the Negro population in Harlem has dwarfed the various settlements of the race in other parts of New York city. In the evolution of Negro communities in the North the dominating motive has always seemed to be economic, until Harlem arose to challenge

the tradition; for here there is no single avenue of employment.

Economic Status.—In Harlem, unlike other American Negro communities, there are no banks, insurance companies, or large realty firms under Negro management. There is no outlet for the young Negro trained in business or finance. Apart from a branch of the Y.W.C.A., a branch of the Y.M.C.A., and half-a-dozen sparsely staffed weekly newspapers, there are few places for Negroes to gain experience as stenographers, book-keepers or accountants. The district has not yet awakened to the necessity of a group consciousness in business. Indeed, the lines of business in which they are engaged are the traditional ones: barbering, hairdressing, operating undertaking establishments, cabarets and employment agencies. Sometimes competition by outsiders is keen in lines which are usually associated with Negro enterprise in cities, such as the management of theatres, restaurants, poolrooms, cabarets and dance halls. With one or two exceptions all the rest—delicatessen stores, drug stores, haberdasheries, ice cream parlors, department stores—are owned and operated by whites. In fact it is recognized in Harlem sociology that the only Negroes of training who dare risk the chances of a career in the community are physicians, lawyers, dentists, preachers, teachers, etc.

Cultural Ascendancy.—In spite of this curious showing Harlem's ascendancy over the rest of the Negro communities of the country is a striking and vital one. Harlem is, to begin with, the goal of the Negro artist, poet, painter, musician or writer. Because Harlem is a part of New York it has done most to focus attention on the creative gifts of the American Negro. Likewise, because of the welter of native Negro races simmering in its orbit, it is a sort of market place for all sorts of ideas concerning Negro life, and the history and the future of the race. It is the fountain head from which spring most of the plans of welfare and conduct and of agitation and protest against mob violence, lynch law, segregation and disfranchisement. So far Harlem represents the most conspicuous civic promise Negroes have enjoyed in the United States of securing the rights and privileges of human equality.

BIBLIOGRAPHY.—For historical data see Washington Irving, *Knickerbocker's History of New York* (1809); J. G. Wilson, *Memorial History of the City of New York* (1892-93); C. H. Pierce, *New Harlem, Past and Present* (1903); and James Riker, *Revised History of Harlem* (1904). (E. WAL.)

NEGUS. (1) The title of a king or ruler (Amharic *negūs* or *n'gūs*), in Abyssinia (*q.v.*); the full title of the emperor is *negūs nagastī*, "king of kings." (2) The name of a drink made of wine, most commonly port, mixed with hot water, spiced and sugared. According to Malone (*Life of Dryden, Prose Works*, i. 484), this drink was invented by a Colonel Francis Negus (d. 1732).

NEHEMIAH, governor of Judaea under Artaxerxes (generally thought to be the first, but more probably the second, of that name, 404-359 B.C.). The book of Nehemiah forms the concluding portion of the great compilation, *Chronicles-Ezra-Neemiah*. Nehemiah's own account, written throughout in the first person, and confined to chapters i.-vi., is the only authentic information which we possess in regard to his life and work. (See further *EZRA AND NEHEMIAH* [Books]; *Jews: History*.)

NEHRU, PANDIT MOTILAL (1861-), Swarajist leader, a Kashmiri Brahman, was born on May 6, 1861. At the Allahabad Bar he came to the front, earning a large income, and exercising hospitality and friendly intimacy with European society. He was for some years a member of the United Provinces legislative council. After the World War, through repression of disorder in the Punjab in 1919, his views changed. In 1919 he founded the *Independent*, an aggressively Nationalist paper, and accepted the presidency of what was now the extremist Indian National Congress. His support of Gandhi's campaign of non-co-operation took the form of suspension of his lucrative practice at the bar and the abandonment of luxurious western habits. At the close of 1921 he was imprisoned for six months for breaking the law against seditious assemblies. He so far modified his non-co-operation attitude as to accept election to the second legislative assembly at the close of 1923, and took his place there as leader of the Swaraj party. On the death of C. R. Das in 1925 he was elected president of the all-India Swaraj party, and under his guidance it was fused in the following year into the National Congress party. This or-

ganization promoted a boycott of the Simon Commission and took the lead in formulating under his chairmanship the All Parties Conference Report, otherwise known as the Nehru Report. It lays down a scheme of Dominion status for India. He presided at the 43rd annual National Congress at Calcutta in the last week of 1928, when acceptance of the scheme by the British Government within a year was demanded as the alternative to widely-organized non-co-operation. (F. H. BR.)

NEILE, RICHARD (1562-1640), English divine, was educated at Westminster school and at St. John's college, Cambridge. He was dean of Westminster (1605); bishop of Rochester (1608), Lichfield (1610), Lincoln (1614), Durham (1617) and Winchester (1628), and archbishop of York (1631). When at Rochester he appointed William Laud as his chaplain and gave him several valuable preferments. Neile sat regularly in the courts of star-chamber and high commission. His correspondence with Laud and with Sir Dudley Carleton and Sir Francis Windebank (Charles I.'s secretaries of state) are valuable historical sources.

NEILL, JAMES GEORGE SMITH (1810-1857): British soldier, was born near Ayr, Scotland, on May 26, 1810, and educated at Glasgow University. Entering the service of the East India Company in 1827, he received his lieutenant's commission a year later. When the Indian Mutiny broke out Neill, who was in command of the 1st Madras Europeans, left Madras with his regiment at a moment's notice, and proceeded to Benares. The day after his arrival he completely and ruthlessly crushed the mutineers (4th June 1857). He next relieved Allahabad, which became the place of concentration for Havelock's column. The two officers, through a misunderstanding in their respective instructions, disagreed, and when Havelock went on from Cawnpore (which Neill had reoccupied shortly before) he left his subordinate there to command the lines of communication.

The famous march from Cawnpore to Lucknow began on September 19th; on the 21st there was a sharp fight, on the 22nd incessant rain, on the 23rd intense heat. On the 23rd the fighting opened with the assault on the Alum Bagh, Neill at the head of the leading brigade recklessly exposing himself. Next day he was again heavily engaged, and on the 25th he led the great attack on Lucknow itself. The fury of his assault carried everything before it, and his men were entering the city when a bullet killed their commander.

See J. W. Kaye, *Lives of Indian Officers* (1889); and J. C. Marshman, *Life of Havelock* (1867).

NEISSE, a town and fortress in the province of Prussian Silesia, at the junction of the Neisse and the Biela, 32 m. by rail S.W. of Oppeln. Pop. (1925) 32,525. Neisse, one of the oldest towns in Silesia, is said to have been founded in the 10th century, and afterwards became the capital of a principality of its own name, which was incorporated with the bishopric of Breslau about 1200. Its first walls were erected in 1350, and it was thrice besieged during the Thirty Years' War. The end of the first Silesian War left Neisse in the hands of Frederick the Great. The Roman Catholic parish church of St. James (Jakobikirche) dates mainly from the 13th century, but was finished in 1430. The chief secular buildings are the old episcopal residence, the old Rathaus (1499), and the beautiful Renaissance *Kämmerei* (exchequer) with a high gabled roof ornamented with frescoes.

NEISSE, three rivers of Germany. (1) The Glatzer Neisse, 121 m. long, rises on the Schneeberg, at an altitude of 1,400 ft., flows north past Glatz, turns east and pierces the Eulengebirge in the Wartha pass, then continues eastward past Neisse until it joins the Oder (left) between Oppeln and Brieg. It is only used for floating down timber but abounds in fish. (2) The Lausitzer or Görlitzer Neisse, 140 m. long, rises near Reichenberg in Bohemia, on the south side of the Riesengebirge, flows north past Reichenberg, Görlitz, Forst and Guben, and enters the Oder above Fürstenberg. Less than 40 m. are navigable. (3) The Wütdende Neisse is a tributary of the Katzbach.

NEJD, a kingdom of Arabia, occupying the core of that ancient land-block. The old block has been uptilted on the west, consequently Nejd tends to slope very gradually from west to east. The name itself implies an upland, and this is its distinc-

tive character as compared with the adjoining coastal districts of Hejāz and El Hasa, representing the shelving down of the plateau on the west and east respectively. In general elevation Nejd varies from 5,000 ft. on its western border to 2,500 in Kasim in the north-east, and somewhat less in the south-east. In the north Jebel Shammar, and in the east J. Tuwēk and J. 'Arid rise about 1,500 ft. above the general level, but, on the whole, Nejd may be described as an open steppe, of which the western and southern portion is desert, or at best pasture land only capable of supporting a nomad population; while in the north and east, owing to greater abundance of water, numerous fertile oases are found with a large settled population. (See ARABIA.)

Nomadic tribes, following their flocks and herds over the steppe, have roamed over the territory from time immemorial, raiding the settled dwellers of the oasis in times of difficulty or scarcity. The four most prominent tribes of Bedouin are the Shammar, Harb, 'Ateba and Mutēr. The first-named represent that part of the great Shammar tribe which has remained in its ancestral home on the southern edge of the Nafud (the northern branch long ago emigrated to Mesopotamia); many of its members have settled down to town life, but the tribe still retains its Bedouin character. The Harb are probably the largest of the Bedouin tribes in the peninsula, and are divided into a number of sections. Their territory is the steppe between Kasim and Medina. The 'Ateba territory extends from near Mecca along the road leading thence to Kasim. The Mutēr occupy the desert from Kasim northwards towards Kuwēt.

Nejd became nominally a dependency of the Turkish empire in 1871, when Midhat Pasha established a small garrison in El Hasa, and created a new civil district under the government of Basra, under the title of Nejd, with headquarters at Hofuf. Its real independence was not, however, affected, and the emirs, Mohammed Ibn Rashid, at Hail, and Abdallah Ibn Sa'ud, at Riad, ruled in Western and Eastern Nejd respectively, until 1892, when the former, by his victory at 'Anēza, became emir of all Nejd. His successor, Abdul Aziz Ibn Rashid, was, however, unable to maintain his position, and in spite of Turkish support, sustained a severe defeat in 1905 at the hands of Ibn Sa'ud, who thus became the dominant power in Nejd. By 1914 Ibn Sa'ud, with his Wahhabi followers had wrested the province of Hasa from the Turks, and his power thus reached the Persian gulf. Remaining inactive during the World War of 1914-18, Ibn Sa'ud in 1920 had captured and annexed Abha and other parts of Asir, leaving only the coastal strip. In 1921, Hail and the dominion of the amir of Jabal Shammar were in his possession, and by the end of 1925 he had overthrown the new Hashimite kingdom of the Hejāz. He was proclaimed at Jidda, in 1926, as king of Hejāz and sultan of Nejd. Thus, from his Nejd capital at Riyādh, Ibn Sa'ud rules over Desert Arabia.

His administration is patriarchal and his law the Sharia, administered by Wahhabi officials. A few simple taxes on cattle and possessions are collected. The chief administrative regions of the sultanate are Hasa; Aridh, with the town of Riyādh; Wadi Dawasir; Aflaj; Kharij; Sudair; Mahmal; Washm; Qasim; Jabal Shammar, with the town of Hail; Jauf; and numerous scattered oasis-groups, each ruled by an amir. Of the towns, Hufuf has a population of about 30,000; Hail, Riyādh, Hauta, Anaiza, Buraida, Jauf, Mubarras, Shagra and Sakaka have populations between 10,000 and 20,000. The entire population of Nejd is estimated at three millions. Besides the population of the towns mentioned above, and the nomadic tribes, there are many villages in hollows of the valleys that cut into parts of the high calcareous tableland. Travellers tell of countless numbers of these hollows, wherein is concentrated the fertility and much of the population of Nejd; gardens, houses, cultivation and villages lie hidden from view among the depths while one journeys over the dry flats, till one comes suddenly on a mass of emerald green beneath.

The products of Nejd include dates, wheat, barley, hides, wool, fruit, *suman* (clarified butter), camels, sheep, horses, etc. The export of camels to Syria and Egypt is important. Tea, coffee, sugar, rice and piece-goods are imported. (See also under ARABIA.)

Euting, *Reise in inner Arabien* (Leyden, 1896); E. Nolde, *Reise nach inner Arabien* (Brunswick, 1895); H. St. J. B. Philby, *The Heart of Arabia* (2 vols., 1922).

NEKRASOV or **NEKRASSOV, NIKOLAY ALEXEYJEVICH** (1821-1877), Russian poet, was born on Nov. 22 (O.S.) 1821, in Podolia, the son of a landowner in the government of Yaroslāv, where the boy was brought up. He studied at St. Petersburg, against the will of his father, who left him to his own resources. At the age of 19 he published a small volume of poems (*Dreams and Sounds*), most of which had appeared in periodicals, and in 1846 he bought from Pletnev the *Sovremennik*, which in his hands became from 1856 onwards the favourite organ of young radical writers. It was suppressed in 1866, but in 1868 Nekrasov acquired, with Saltykov, the *Otechestvennye Zapiski*, in which the traditions of the *Sovremennik* were maintained. He died at St. Petersburg on Dec. 27 (O.S.) 1877.

Nekrasov was a people's poet, and expressed the sorrows and sufferings of the common people in poems which made him the idol of the reformers, and the joy and humour of every-day life in admirable adaptations of folksong, and in charming poems for children. Among the most famous of his works are *The Red-Nosed Frost* (1863), depicting a heroic peasant woman, and the great satirical work "*Who can be happy and free in Russia?*" (1879, Eng. trans. J. M. Soskice, 1901.) The latter is a species of *Canterbury Tales*, though with a definite purpose running through the series. Seven peasants make their way on foot throughout Russia to solve the question of who is happy. They are told a series of tales, by typical characters, landowners, priests, peasants and others, and Nekrasov concludes on a note of hope for the future. This last canto, owing to the censorship, did not appear until 1881. His work includes love poems, elegies and narrative poems. The most recent edition of his poems was published in 2 vols. in 1919, and they have been translated into German by H. J. Köcher (2 vols. Leipzig, 1885-88). English translations of some of his poems, including *The Red-Nosed Frost*, are to be found in C. T. Wilson's *Russian Lyrics* (1887); and J. Pollen, *Rhymes from the Russian* (1891). See also a French translation of some of his poems *Poésies populaires*, by E. Halperine-Kaminsky and C. Morice, with a preface by E. M. Vogüé.

NEKTON, the name applied collectively to the larger, actively swimming animals of the open sea (mainly fishes), in contradistinction to the passively drifting plankton (*q.v.*), and the sedentary, bottom-living benthos (*q.v.*). (See MARINE BIOLOGY.)

NELEUS, in Greek legend, son of Poseidon and Tyro, brother of Pelias. The two children were exposed by their mother, who afterwards married Cretheus, king of Iolcus in Thessaly. After the death of Cretheus, the boys, who had been brought up by herdsmen, quarrelled for the possession of Iolcus. Pelias expelled Neleus, who migrated to Messenia, where he became king of Pylos (Apollodorus i. 9; Diod. Sic. iv. 68) and ancestor of the Neleidae, who are historically traceable as the old ruling family in some of the Ionic states in Asia Minor, after the Dorian migration. By Chloris, daughter of Amphion, Neleus was the father of 12 sons (of whom Nestor was the most famous) and a daughter Pero; *cf.* MELAMPUS. According to Pausanias (ii. 2. 2, v. 8. 2) Neleus restored the Olympian games and died at Corinth, where he was buried on the isthmus.

NELLORE, a town and district of India, in the Madras presidency. The town is on the right bank of the Penner river, and has a station on the East Coast railway, 109 m. N. of Madras city. Pop. (1921) 35,863. There are Lutheran, American Baptist and Roman Catholic missions, and a college.

The DISTRICT OF NELLORE has an area of 7,973 sq.m. It comprises a tract of low-lying land extending from the base of the Eastern Ghats to the sea. Its general aspect is forbidding: the coast-line is a fringe of blown sand through which the waves occasionally break. Farther inland the country begins to rise, but the soil is not naturally fertile, nor are means of irrigation readily at hand. About one-half of the total area is cultivated; the rest is either rocky waste or is covered with low scrub jungle. Nellore, with the other districts of the Carnatic, passed under

direct British administration in 1801. The population in 1921 was 1,385,553. The principal crops are millets, rice, and pulses. The breed of cattle is celebrated. The East Coast railway runs through the length of the district.

NELSON, HORATIO NELSON, VISCOUNT (1758-1805), duke of Bronte in Sicily, British naval hero, was born at the parsonage house of Burnham Thorpe, in Norfolk, on Sept. 29, 1758. His father, Edmund Nelson, was rector of the parish and his mother, Catherine Suckling, was a grandniece of Sir Robert Walpole (1st earl of Orford). This connection proved useless to the future admiral, who, in a letter to his brother, the Rev. William Nelson, written in 1784, speaks of the Walpoles as "the merest set of cyphers that ever existed—in public affairs I mean." His uncle, Captain Maurice Suckling later became comptroller of the navy.

Early Life.—Horatio, who had received a summary, and broken, education at Norwich, Downham and North Walsham, was entered on the "Raisonné" when Captain Suckling was appointed to her in 1770 on an alarm of war with Spain. The dispute was settled, and Captain Suckling was transferred to the "Triumph," the guardship at Chatham, whither he took his nephew. In order that the lad might have more practice than could be obtained in a harbour ship, his uncle sent him to the West Indies in a merchant vessel, and on his return gave him constant employment in boat work on the river. In a brief sketch of his life, which he drew up in 1799, Nelson says that in this way he became a good pilot for small vessels "from Chatham to the Tower of London, down the Swin, and the North Foreland; and confident of myself among rocks and sands, which has many times since been of great comfort to me." Between April and October of 1772 he served with Captain Lutwidge in the "Carcass," in an expedition to the Arctic seas under the command of Captain Phipps (Baron Mulgrave). On his return from the north he was sent to the East Indies in the "Seahorse," in which vessel he met his lifelong friend Thomas Troubridge. At the end of two years he was invalidated home. In after times he spoke of the depression under which he laboured during the return voyage, till "after a long and gloomy reverie, in which I almost wished myself overboard, a sudden glow of patriotism was kindled within me, and presented my king and my country as my patron. My mind exulted in the idea. 'Well then,' I exclaimed, 'I will be a hero, and, confiding in Providence, I will brave every danger.'" He spoke to friends of the "radiant orb" which from that hour hung ever before him, and "urged him onward to renown." On his return home he served during a short cruise in the "Worcester" frigate, passed his examination as lieutenant on April 9, 1777, and was confirmed in the rank next day. He went to the West Indies with Captain Locker in the "Lowestoft" frigate, was transferred to the flagship of Sir Peter Parker (1721-1811), and was then promoted in rapid succession to the command of the "Badger" brig, and the "Hinchinbrook" frigate. By this appointment, which he received in 1779, he was placed in the rank of post captain (from which promotion to flag rank was by seniority), at the age of twenty. In the main he owed his rapid rise to his power of winning the affection of his comrades or superiors. Parker and his wife remained his friends through life.

Active Service.—In 1780 he saw his first active service in an expedition to San Juan de Nicaragua; he was brought to death's door by fever, and invalidated home once more. In 1781 he was appointed to the "Albemarle" frigate, and after some convoy service in the North Sea and the Sound was sent to Newfoundland and thence to the North American station. "Fair Canada," as he has recorded in one of his letters, gave him the good health he had so far never enjoyed. From Quebec he sailed for the West Indies, where he made the personal acquaintance of Admiral Lord Hood. The admiral presented him to the duke of Clarence, afterwards King William IV., as an officer well qualified to instruct him in "naval tactics"—a marked compliment to a very young officer from one of the greatest exponents of the art. He appeared, says the Prince, "to be the merest boy of a captain I ever beheld; and his dress was worthy of attention. He had on a full-laced uniform; his lank unpowdered hair was tied

in a stiff Hessian tail of an extraordinary length; the old-fashioned flaps of his waistcoat added to the general quaintness of his figure, and produced an appearance which particularly attracted my notice; for I had never seen anything like it before, nor could I imagine who he was or what he came about. My doubts were, however, removed when Lord Hood introduced me to him. There was something irresistibly pleasing in his address and conversation; and an enthusiasm, when speaking on professional subjects, that showed he was no common being." The slight oddity of appearance, the power to arouse affection, and the glow indicating the fire within, are noted by all who ever looked Nelson in the face.

The Peace of Versailles which closed the American War gave him leisure to visit France, there to study the language of his "country's enemies" and their writings on the subject of naval warfare. And now when the vast majority of naval officers were condemned to idleness on shore, he had the good fortune to be appointed to the command of the "Boreas" frigate, for service in the West Indies. Nelson signalized his arrival in the West Indies by refusing to acknowledge a half-pay officer acting as commissioner of the dockyard at Antigua as his superior. He insisted on enforcing the Navigation Laws against the Americans, who by becoming independent had become foreigners. He called the attention of the government to the corruption prevailing in the dockyard of Antigua. His line impressed the admiralty as somewhat assuming, and his strong measures against the interloping trade brought on him many lawsuits, which, though he was defended at the expense of the government, caused him much trouble for years. In the West Indies on March 12, 1787, he married Frances Nisbet (1761-1831), the widow of a doctor in Nevis, whose favour he first gained by being found romping on all fours with her little boy under the drawing-room table. The marriage was one of affection and prudence, rather than of love.

Outbreak of War.—When war broke out with revolutionary France, Nelson was appointed (Nov. 30, 1793) captain of the "Agamemnon" (64), and joined his ship on Feb. 7. From this date till June 1800, rather more than seven years, he was engaged on continual active service, with the exception of a few months when he was invalidated home. This period is the most varied, the busiest, the most glorious and the most debated of a very full career. It subdivides naturally into three sections: (1) From the date of his appointment as captain of the "Agamemnon" till he was disabled by the loss of his arm in the unsuccessful attack on Santa Cruz de Tenerife on July 24, 1797, he served as captain, or commodore, under Hood, Hotham and Jervis, successive commanders-in-chief in the Mediterranean. (2) After an interval of nine months spent at home in recovering from his wound, and from the effects of a badly performed operation, he returned to the Mediterranean, and was at once sent in pursuit of the great French armament which sailed from Toulon under the command of Napoleon for the conquest of Egypt. His victory of the Nile (*q.v.*), on Aug. 1, 1798, placed him at once in the foremost rank among the warriors of a warlike time, and made him a national hero. (3) From his return to Naples after the battle of the Nile until his return to England in the summer of 1800, he was immersed in Mediterranean affairs which, owing to his own presence there, tended to centre round the shores of Naples and Sicily.

The Mediterranean.—The first of these three passages in his life is full of events which must, however, be told briefly. In May he sailed for the Mediterranean with Hood, and was engaged under his orders in the occupation of Toulon by the allied British and Spanish forces. In August 1793 he was despatched to Naples to convoy the troops which the Neapolitan government had undertaken to contribute towards the garrison of Toulon. It was on this occasion that he made the acquaintance of Emma Hamilton (*q.v.*), the wife of Sir William Hamilton, minister at the Court of Naples. References to Lady Hamilton begin to appear in his letters to his wife, but, as might be expected, they indicate little beyond respectful admiration, and he makes a good deal of her kindness to his stepson, Josiah Nisbet, whom he had taken to sea. After the allies had been driven from Toulon by

Napoleon, Nelson was employed throughout 1794 in the operations connected with the occupation of Corsica. In April and May he was engaged in the capture of Bastia, and June and July in the taking of Calvi. During the operations at Calvi, Nelson received a wound in his right eye which healed without leaving disfigurement, though the sight gradually faded. From the date of the occupation of Corsica till the island was evacuated (1794-96) he was incessantly active. He served under Hotham, who succeeded Hood in the command, and was engaged in the indecisive actions fought by him in the Gulf of Lyons in March and July 1795. The complacency of the new admiral fretted the eager spirit of Nelson, who declared that, for his part, he would never think that the British fleet had done very well if a single ship of the enemy got off while there was a possibility of taking her. Happily he was detached to the Riviera of Genoa, where, first as captain, and then as commodore, he had an opportunity to prove his qualities for independent command by harassing the communications of the French, and co-operating with the Austrians. In Sir John Jervis, who superseded Hotham, he found a leader after his own heart. When Spain, after first making peace with France at Basel, declared war on England, and the fleet under Jervis withdrew from the Mediterranean, Nelson was despatched to Elba on a hazardous mission to bring off the small garrison and the naval stores. He sailed in the "Minerve" frigate, having another with him. After a smart action with two Spanish frigates which he took off Carthagena on Dec. 20, and a narrow escape from a squadron of Spanish line of battle ships, he fulfilled his mission, and rejoined the flag of Jervis on the eve of the great battle (Feb. 14, 1797) off Cape St. Vincent. (*See ST. VINCENT, BATTLE OF.*) The judgment, independence and promptitude he showed in this famous engagement revealed him to the nation as one of the heroes of the navy. Nelson receiving the swords of the Spanish officers on the deck of the "San Josef" became at once a popular figure.

Blockade of Cadiz.—A few days after the victory he became rear-admiral by seniority, but continued with Jervis, who was made a peer under the title of Earl St. Vincent. Nelson's own services were recognized by the K.B. During the trying months in which discontent in the fleet was developing toward the mutinies at Spithead and the Nore, he remained with the flag, and in the blockade of Cadiz. In July 1797 he was sent to Santa Cruz de Tenerife and made a desperate attempt to capture the place. The enterprise was, in fact, rash in the last degree, for the soldiers from the garrisons of Elba and Corsica having gone home, no troops were available for the service, and a fortified town was to be taken by man-of-war boats alone. The Spaniards were on the alert, and the attack, made with the utmost daring on the night of July 24, was repulsed with heavy loss. Some of the boats missed the mole in the dark and were stove in by the surf, others which found the mole were shattered by the fire of the Spaniards. Nelson's right elbow was shot through, and he fell back into the boat from which he was directing the attack. The amputation of his arm was badly performed in the hurry and the dark. He was invalided home, and spent months of extreme pain in London and at Bath. On April 10, 1798, he came back to the fleet off Cadiz as rear-admiral, with his flag in the "Vanguard" (74).

He was now one of the most distinguished officers in the navy. Within the next six months he was to raise himself far above the heads of all his contemporaries. A great armament was preparing at Toulon for some unknown destination. To discover its purpose, and to defeat it, the British government resolved to send their naval forces again into the Mediterranean, and Nelson was chosen for the command not only by Jervis, with whom the immediate decision lay, but also by ministers.

Command in the Mediterranean.—Having joined the flag of Lord St. Vincent outside of the straits of Gibraltar on April 30, Nelson was detached on May 2 into the Mediterranean, with three line-of-battle ships and five frigates, to discover the aim of the Toulon armament. Napoleon had, however, enforced rigid secrecy, and beyond the fact that a powerful combined force was collected in the French port he could learn nothing. On May 20

the "Vanguard" was dismasted in a gale. "I ought not," wrote Nelson, "to call what has happened by the cold name of accident; but I believe firmly that it was the Almighty's goodness to check my consummate vanity." The "Vanguard" was saved from going on shore by the skill of Captain Ball of the "Alexander," for whom Nelson had henceforth a peculiar regard. The "Vanguard" was refitted under cover of the little island of San Pietri off Sardinia. In the meantime the frigates attached to his command had returned to Gibraltar, in the erroneous belief that the liners would be taken there to make good the damage suffered in the gale. "I thought Hope would have known me better," said Nelson. On April 30 he was off Toulon again, only to find that the French were gone. Deprived of his best means of obtaining information by the disappearance of his frigates, he remained cruising till he was joined, on June 7, by Troubridge with ten sail of the line. And now he started on his fierce pursuit of the enemy, seeking him in the dark, for there were no scouts at hand; exasperated at being left without the eyes of his fleet; knowing that St. Vincent would be blamed for choosing so young an admiral; but resolved to follow the enemy to the antipodes if necessary. From Sardinia to Naples, from Naples to Messina, from Messina to Alexandria, from Alexandria, where he found the roadstead empty, back to Sicily, and then when at last a ray of light came to him, back to Alexandria—he swept the central and eastern Mediterranean. Unlike most admirals of his time, he freely discussed his plans with his captains. He had his reward in their devotion and perfect comprehension of what he wished them to do. At the same time he acquired an absolute confidence in the efficiency of his squadron, the magnificent force which had been formed by years of successful war, and by the careful training of his predecessors. The captains were the band of brothers he himself had made them.

The great victory of Aug. 1, 1798 (*see NILE, BATTLE OF*), brought Nelson yet another wound. He was struck on the forehead by a langridge shot, and had for a time to go below. For this victory he was made a baron.

Blockade of Naples.—After providing for the blockade of what remained of the French in Alexandria, Nelson set sail for Naples and arrived there on September 22nd. Pitt's Second Coalition against France was then on the point of completion, and Naples, naturally enough in view of the French behaviour on her borders, was preparing to side with Austria and Russia in the defence of monarchy; indeed she was already organising an army under the direction of the Austrian general, Mack, but no decision as to how the troops should be used had as yet been arrived at. Nelson immediately tried to enliven the proceedings, and suggested what should have been a perfectly feasible plan, by which the Neapolitan Army was to advance northwards against the French front, while the fleet was to capture Leghorn, thus cutting the French communications. Leghorn was duly taken, but the army showed little aptitude for fighting, soon becoming a mere disorderly rout, pursued by the French. This had the effect of rousing all the Jacobins in the country which was soon in such an uproar that the royal family found it necessary to retreat to Palermo—an evacuation carried out of course by Nelson and his ships, with the valuable co-operation of Lady Hamilton (*q.v.*), wife of the British Ambassador. From Palermo, Nelson kept up a double blockade—one squadron under Captain Ball was detached to force Malta to capitulate, and another, under Captain Troubridge, was sent to the Bay of Naples to operate against the Neapolitan Jacobins.

The King and Queen, however, found this method of blockade too slow, and determined to appeal to the conservative instincts of many of their subjects, who had lazily acquiesced in the Jacobin coup d'état, through the agency of an eminent ecclesiastic—Cardinal Ruffo. His Eminence landed in Italy, and his appeal for an "Army of the faith" was soon answered by thousands flocking to his banner, and he was even joined by a detachment of Russians and Turks. While these events were taking place, a French fleet of 26 vessels, under Admiral Bruix, set out from Brest and was joined by 17 Spanish warships at Cartagena. Such a force constituted a threat to Nelson who called up his ships

PORTRAITS OF LORD NELSON AND SCENES RELATING TO HIS LIFE

1. "Lord Nelson in the cabin of the *Victory*," after a painting by C. Lucy
2. Admiral Lord Nelson, after the portrait by L. F. Abbott
3. "Lord Nelson being carried below in the *Victory* after being fatally wounded at the Battle of Trafalgar, Oct. 21, 1805." Engraved by James Walker after a painting by J. A. Atkinson
4. The Nelson Monument, Trafalgar Square, London. This monument, consisting of a granite column 168½ feet high surmounted by a statue of Nelson, was completed in 1849 and stands in the southern side of the square, which is named in commemoration of the admiral's last victory. On the base are represented four battle scenes in bronze, cast from the metal of captured French cannon
5. The "*Victory*," Nelson's flagship at Trafalgar, now moored in Portsmouth harbour, England. It was repaired in 1921
6. "Rear Admiral Sir Horatio Nelson in the uniform of the blue." Engraved in 1798 by W. Barnard after a painting by L. F. Abbott
7. "Destruction of the French and Spanish prizes after the victory of Trafalgar." Engraved in 1806 by L. Hall after a painting by J. T. Serres
8. The rectory at Burnham Thorpe, Norfolk, where Nelson was born Sept. 29, 1758. The building was pulled down in 1802
9. "Representation of the Memorable Battle of Trafalgar," an engraving by Jos. Teakes after a contemporary painting, showing the British fleet engaging the combined fleets of France and Spain. The flagship "*Victory*" is second from the right

from Malta and Naples and prepared for resistance. He managed, however,—and this was important in view of Ruffo's successful beginning—to maintain the blockade of the latter by means of a squadron of small ships placed under Captain Foote of the frigate "Seahorse."

The Franco-Spanish threat proved an idle one and the allied fleet soon retired, but, in the meanwhile, Ruffo was driving all before him and finally shut up the French in the Castle of St. Elmo, in the city of Naples, and the native insurgents in the sea-washed castles of Uovo and Nuovo. From this commanding position he began to parley with the enemy, and the king, hearing of this, and nervous of what the Cardinal might do—he had not been empowered to make terms of peace—asked Nelson to proceed to Naples and take matters into his hands.

Ruffo's Treaty of Peace.—Nelson sailed for Naples, with Sir William and Lady Hamilton on board, on June 21st, and arrived there on the 24th to find the white flag flying from the castles and from his own flotilla. Supposing this to indicate an armistice, he at once made signal for the resumption of hostilities, only shortly to be informed by Captain Foote that matters had gone further and that a treaty of peace had been signed by which the native insurgents were to be allowed to leave their strongholds with all the honours of war, and were to be carried by ship to countries that would be glad to receive them. In making such a treaty there can be no doubt that Ruffo had greatly exceeded his instructions, though it is probable that he was actuated by motives of humanity since his control over his bloodthirsty army was incomplete. Nelson refused to listen to Ruffo's arguments or to admit the validity of his undertakings. Furthermore, he argued, there was no need for the insurgents, if they unconditionally surrendered as he proposed to make them, to trust themselves to the mob on shore, since they could be accommodated in boats without being taken to friendly countries. He agreed to let the armistice run its course, but let it be known that at the end of it he would expect unconditional surrender. This he received, and the rebels were placed in boats. One, Carraciolo, reached the hills, only to be caught at last and brought to Ruffo who, in his turn, because Carraciolo was a naval officer, handed him over to Nelson in his capacity as Commander-in-Chief of the Neapolitan fleet. Nelson at once convened a court martial of Neapolitan officers to try the rebel. The Court sentenced him to death by a majority vote, and this sentence was duly carried out.

For refusing to carry into effect Ruffo's peace terms and for not interfering to prevent the execution of Carraciolo, Nelson has been violently, and at times virulently, attacked, but it cannot be said that his traducers had ever succeeded in making out a very strong case against him. The whole matter is too involved to be fully discussed here; the conclusions which have been reached by scholars on either side have almost invariably reflected the political *parti pris* of the writers.

The whole question of Nelson's conduct at Naples is of course bound up with his friendship with Lady Hamilton. No one denies that it was now that Nelson's friendship for this woman ripened into the intimacy that was eventually to separate him from his wife. But that a private attachment, culpable as it may have been, warped his judgment in public matters no one has yet shown, nor has anyone explained why it should.

Return to England.—These events were shortly followed by the reduction of the French and by the restoration of the Neapolitan royal family in July, while in the same month Nelson laid himself open to a sharp rebuke from the Admiralty for disobeying the orders of Lord Keith who had been appointed to succeed Lord St. Vincent in the Mediterranean command. Keith, puzzled as to the objective of a combined Franco-Spanish fleet, decided that Minorca was in danger, and ordered Nelson to its defence. Nelson decided that it was not in danger and did not go. His judgment was correct, but his disobedience was inexcusable. On Jan. 20th, 1800, having in the meantime been created Duke of Bronté by the King of Naples, Nelson joined Keith at Leghorn to take part in an attempt on Corsica, during which he captured "Le Généreux" which had escaped him at the Nile. Shortly afterwards he obtained leave to go home and, not being spared a battle-

ship, he travelled overland with Sir William and Lady Hamilton, being greatly fêted on the way. He landed in England in November.

Battle of Copenhagen.—His leave, though it was long enough to promote the final separation between him and his wife, was short. He became Vice-Admiral on Jan. 1, 1801, and soon after was offered the post of second-in-command to Sir Hyde Parker in the fleet which was to break up the armed neutrality of the northern powers. It is difficult to see why such a brilliant man was subordinated to one of such ordinary gifts as Parker, who appears at the beginning to have been suspicious of the abilities of his second-in-command. Nelson, however, choked down his natural disgust, and treated Parker with such tact that the Admiral's hostility soon melted into something approaching friendship. Indeed Nelson had his Commander-in-Chief to some extent under his thumb by the time they reached Copenhagen, and so was permitted, with rather more than half the fleet, to carry out his famous attack on the city and its defences that resulted in the battle of Copenhagen (*q.v.*). This battle showed up strongly Nelson's ability to hit upon the weak point in a defensive scheme, and is famous also for his action in putting his telescope to his blind eye when, in the middle of the fight, his attention was directed to Parker's signal ordering his withdrawal, and declaring he could not see it. It was an order that could not be obeyed without serious consequences to the fleet. In May, Parker was recalled and Nelson assumed the command, but the armed neutrality was dissolved and this left him with little to do. His health, too, was bad and in June he came home, his services being recognised by the bestowal of the title of Viscount. In the interval, before the Peace of Amiens, he was in command of a flotilla of small ships that were to combat Napoleon's threat of invasion. More in the hope of satisfying public opinion than for any other reason, an attack was launched on Boulogne with the object of destroying the flat-bottomed boats situated there. The port, however, was too strongly defended even for a Nelson.

During the short period of the Peace of Amiens (1802-3), Nelson, in company with Sir William and Lady Hamilton, lived at his house and estate that he had purchased at Merton in Surrey. Here he passed his days in quiet country pursuits, and his happiness was added to by a reconciliation with his father who had at first found it impossible to overlook his son's association with Lady Hamilton. This, probably the happiest period of his life, was all too short. War reopened in May, and Nelson was at once selected for the Mediterranean Command.

The Mediterranean Command, 1803.—He arrived off Toulon in July 1803, and instituted a strict blockade of that port. The French under Latouche-Tréville continually tried to lure him into indecisive actions in which, by damaging some of his ships, they might force him to withdraw, but Nelson consistently refused such offers and the French Admiral, writing to Napoleon, stated that he had offered battle but the English had withdrawn. Nelson declared that if he captured Tréville he would make him eat the letter, but he never had the chance to fulfil his boast, even figuratively, for Tréville died and was succeeded by Villeneuve. In the spring of 1805 the French eluded the blockade and made for the West Indies. This move was part of a large scheme directed towards the invasion of England and its details are too numerous for discussion. The series of naval movements arising from it are known as the Trafalgar Campaign, and the whole matter will be found fully dealt with under the title NAPOLEONIC WARS. Nelson, after searching the Mediterranean, decided, more by intuition than anything else, that Villeneuve had gone to the West Indies, and thither he followed him. On hearing of his enemy's arrival, Villeneuve returned precipitately to Europe, again pursued by Nelson, and got into Ferrol and then into Cadiz where he was blockaded by Collingwood, Nelson having meanwhile gone home on leave to enjoy again the rural delights of Merton. His enjoyment was indeed brief. No sooner had the news reached England that the allied fleet was in Cadiz than, with the approval and encouragement of Lady Hamilton, he offered his services, "to give M. Villeneuve a drubbing." They were immediately accepted, and he left Merton for the last time

on Sept. 13th and on the 29th was off to Cadiz.

Trafalgar.—The victory of Trafalgar (*q.v.*) which followed on Oct. 21 set the seal on his fame. Tactically it was a masterpiece and his famous signal "England expects that every man will do his duty," made as the fleet moved into battle, together with his death in the moment of victory, added, and still add, to its lustre. The "Victory," after passing through the French line, was engaged with the "Bucentaure" and the "Redoubtable," and Nelson, as he walked up and down his quarter-deck with his flag-captain, Thomas Hardy, was struck by a bullet from a sharp-shooter firing from the top of the last-named ship. His spine was broken, and he was carried below to the cockpit, suffering great pain. Here, amidst the din and racket of battle and the groans of the injured and dying, he lingered for a few hours. To the last he retained his interest in the battle and Hardy came to him from time to time to tell him of its progress. As his sight grew dimmer and he felt the end approaching he asked Hardy to kiss him. "Now I am satisfied," he said, "Thank God I have done my duty." "These words," says Southey in his moving account, "he repeatedly pronounced and they were the last he uttered." His body was brought home and laid in state in the Painted Hall at Greenwich Hospital, and was buried in St. Paul's.

So died the most famous of English seamen, and, indeed, the most famous of all seamen. He was more than merely a tactically and strategically brilliant Commander; he was a true leader of men—and men of all types, for the common seamen trusted and venerated him as much as did his officers. These latter were, in their turn, trusted by him and were ever in his confidence—his "band of brothers" he called them. No officer under Nelson could ever complain that he went into action not knowing his Commander's plans and intentions—and it is as much to this as to his tactical ability that his successes were due. The common seamen he always treated with humanity and kindness and these qualities were extended to his junior officers whom, remembering his own misery during his first days at sea, he was ever willing to encourage. On the other side it has been said that he was vain, liked flattery, and was an egotist. This is merely to say that he had the common faults of genius.

Nelson had no children by his wife. In November 1805, in recognition of Nelson's great services to his country, his brother William (1757–1835) was created Earl Nelson of Trafalgar, an annuity of £5,000 being attached to the title.

BIBLIOGRAPHY.—Southey's "Life of Nelson" edited by Professor Geoffrey Callender (1922). This contains a full bibliography.

(D. H.; X.)

NELSON, a town in British Columbia, situated at the head of navigation on the west arm of Kootenay lake. Pop. (1921) 5,230. It is the commercial and administrative centre of a mining, lumbering, fruit-growing district and is the headquarters of the Kootenay division of the Canadian Pacific. It is also a station on the Great Northern railway.

NELSON, a municipal borough in the Nelson and Colne parliamentary borough, Lancashire, England, 32½ m. N. from Manchester by L.M.S. railway. Pop. (1921), 39,841. Of modern growth, it possesses a town hall, market hall, free library, technical school, park and recreation ground, and an extensive electric tramway system connecting with Burnley and Colne. Its chief manufacture is cotton weaving, and, in recent years, the weaving of artificial silk. It was incorporated in 1890.

NELSON, a seaport of New Zealand, the seat of a bishop and capital of a provincial district of the same name; at the head of Tasman Bay on the northern coast of the South Island. Pop. (1927) 12,010. The woods and fields in the neighbourhood abound with English song-birds, and the streams are stocked with trout; while the suburbs and the district surrounding are famous for apple orchards; and hops are extensively cultivated. The town possesses boys' and girls' colleges of high repute. The cathedral (Christ Church) is finely placed on a mound which was originally intended as a place of refuge from hostile natives. The harbour, with extensive wharves, is protected by the long and remarkable Boulder Bank, whose southern portion forms the natural breakwater to that anchorage. The settlement was planted by the New

Zealand Company in 1842.

NELSON, a river of Keewatin district, Canada, discharging the waters of Lake Winnipeg in a north-easterly direction into Hudson Bay. It drains an area of 360,000 sq.m. and, including its tributary the Saskatchewan, is 1,450 m. long. It is navigable for small steamers for a distance of about 80 m., after which it is unnavigable except for canoes. It has a total fall between the lake and sea of 710 ft. Here its chief tributary is the Burntwood. Norway House at its source and York Factory at its mouth are important stations of the Hudson's Bay Company.

NELSONVILLE, a city of Athens county, Ohio, U.S.A., 62 m. S.E. of Columbus, on the Hocking river and the Hocking Valley railway. Pop. (1920) 6,440 (94% native white). It is an important coal-mining centre, and makes brick and tile from the clay which abounds in the vicinity. The city was founded in 1818 and incorporated in 1838. It was named after Elisha Nelson, who built the first house.

NEMATHELMINTHES, a term employed in zoology to denote a phylum of animals comprising the round-worms (*Nematoda*, *q.v.*) hook-worms (*Acanthocephala*), *Nematomorpha* (*q.v.*), to which are sometimes added the arrow-worms (*Chaetognatha*, *q.v.*), and various other groups of minor importance and doubtful affinities. *Nemathelminthes* is probably, even in its most restricted sense, an artificial group.

NEMATODA, a group of unsegmented worms ("thread-worms"), frequently regarded as forming, with the *Nematomorpha* and *Acanthocephala* (*qq.v.*), a phylum *Nemathelminthes*, but of extremely doubtful affinities. The form of the body is generally cylindrical, and the worms vary in length from a fraction of a millimetre to about a metre. A large number of nematodes (mostly of very small size) are free-living, and occur in water (fresh and marine), soil, moss or decaying substances; while many others are wholly or partly parasitic on plants or in the bodies of other animals, and may be of considerable economic or medical importance.

General Morphology.—The body-wall consists of (1) a tough, elastic, homogeneous cuticle, sometimes provided with spines or bristles; (2) a thin syncytial subcuticular layer; and (3) a single layer of muscle-cells which vary considerably in form and arrangement, but act only in a longitudinal direction. The musculature is divided into four longitudinal strips by internal thickenings of the subcuticular layer, the lateral "fields" and dorsal and ventral lines. The body-cavity, bounded by the muscles, contains a fluid in which the internal organs lie free. The mouth, situated at the anterior end, leads either into a buccal

FROM DE MAN, "DIE NEMATODEN" (E. J. BRILL)

FIG. 1.—LATERAL VIEW OF FREE-LIVING FEMALE NEMATODE

cavity lined with cuticle or directly into the oesophagus, which is usually a three-sided muscular organ, but occasionally consists of a single column of cells surrounding a cuticular tube. The intestine is usually straight, and generally opens through a short rectum and an anus near the hinder end of the body.

The nervous system consists of a perioesophageal ring giving off nerves anteriorly and posteriorly. The chief sense organs are tactile papillae or bristles on the cuticle, situated mainly near the extremities. In certain free-living forms ocelli or "eye-spots" are present internally in connection with the oesophagus, and

sometimes possess lenses. A pair of special lateral cephalic organs, or "amphids," of uncertain function, exists in most free-living forms.

The excretory system consists either of a simple unicellular gland, connected with a minute ventral pore in the oesophageal region, or (in parasitic forms) of a pair of canals running in the

FIG. 2.—TRANSVERSE SECTION THROUGH THE BODY OF A FEMALE (*ASCARIS LUMBRICOIDES*), SHOWING THE BODY CAVITY, BOUNDED BY MUSCLES, IN WHICH THE INTERNAL ORGANS ARE SUSPENDED

lateral fields and joining anteriorly to open by a ventral pore. These canals are without cilia or flame-cells. Special respiratory and circulatory organs are absent.

The sexes are usually distinct. In the male the genital canal and the intestine open into a common cloaca. In the female the anus and genital aperture (vulva) are separate, the latter opening on the ventral surface at a very variable distance in front of the former. The males are usually smaller and less numerous than the females. The reproductive glands are blind, tubular and often much-coiled organs, continuous with their ducts. In the male there is most often a single testis (occasionally two). The spermatozoa are usually tailless, rounded or amoeboid cells. Secondary male organs in the form of chitinous copulatory spicules and one or more "accessory pieces" are usually present in connection with the cloaca. The vagina of the female leads into a uterus with usually two (sometimes more, or only one) long branches, acting as egg-reservoirs, and each connected distally with its own ovary. The ova are fertilized in the uterus, and here also, in oviparous species, a firm chitinous shell is usually formed round them before oviposition.

FROM RUDOLF LEUCKART, "DIE PARASITEN DES MENSCHEN"

FIG. 3.—*ENTEROBIUS VERMICULARIS*, MALE ON RIGHT, FEMALE ON LEFT (HIGHLY MAGNIFIED)

Changes in the form of the buccal cavity and oesophagus may accompany these moults, but the sexual organs do not become fully differentiated until after the third moult. In many forms the cuticle of the second moult is not immediately shed, but serves as a loose protective sheath until the larva finds its proper habitat. This is especially the case with the "infective" larvae of many parasitic forms, which do not shed the second cuticle until they find their way into the host. At this "ensheathed" stage larval

nematodes are often very resistant to low temperatures and to desiccation, and may remain in a state of latent vitality for long periods.

Nematodes may be oviparous, ovoviviparous or viviparous. The free-living forms commonly produce relatively few and large eggs or young. Most of the parasitic forms, however, produce eggs or young, of much smaller relative size, in enormous numbers. These generally reach the exterior with the faeces of the host. The life-history of parasitic species may involve only one host, in which case the larvae (sometimes still in the egg-shell), may be taken in passively by the mouth with contaminated food or water, or may actively penetrate the skin or mucous membranes. On the other hand, an intermediate host (usually an arthropod or lower vertebrate) may be required, in whose tissues or body-cavity the third-stage larva remains encapsulated until swallowed, along with its host, by the final or definitive host.

Classification and Life-Histories.—The nematodes may, for the most part, be classified in five main groups, as follows:

I. *Ascaroidea*. Free-living or parasitic forms having normally three lips (one dorsal and two subventral). This group embraces several well marked families of parasitic forms (*Ascaridae*, *Heterakidae*, *Oxyuridae*, etc.) as well as almost all the purely free-living forms (*Trilobidae*, *Alaimidae*, *Chaetosomatidae*, *Desmoscolecidae*, *Oncholaimidae*, etc.), together with the families

BY COURTESY OF THE EGYPTIAN SCHOOL OF MEDICINE

FIG. 4.—*STRONGYLOIDES STERCORALIS*

Rhabditidae and *Mermithidae*, which are partly parasitic, and the *Anguilluliniidae* (*Tylenchidae*), many of which attack plants.

The life-history of the *Ascaroidea* is usually direct, though some of the *Ascaridae* require an intermediate host. The infective larvae of *Ascaris* and some other genera have a complex migration within the body of the final host, travelling by way of the blood-stream to the lungs, whence they return by the trachea to the mouth, before finally settling in the intestine. In the *Oxyuridae*—e.g., the common "threadworm" or "pinworm" (*Enterobius vermicularis*) of man—the eggs, as soon as laid,

commonly contain infective larvae, rapid infection of new hosts, or constant reinfection of the same host, thus being possible. In some of the Rhabditidae (including the human parasite, *Strongyloides stercoralis*) a free-living bisexual generation alternates with a parasitic generation consisting of "female" forms only. In the Mermithidae the sexual forms are free-living, the larval stages parasitic, chiefly in insects.

II. Strongyloidea. Parasitic forms in which the male is provided with a caudal "bursa" supported by a definite system of "rays." The more important families are the Strongylidae, Ancylostomidae (hookworms), Metastrongylidae and Trichostrongylidae.

The life-history is usually direct, the infective larvae usually being taken in by the mouth, but in some cases—e.g., the hookworms—being able to penetrate the skin. Migration within the host's body is frequent. In the case of the hookworms it follows a similar course to that of *Ascaris*. The adults of the Metastrongylidae inhabit chiefly the air-passages and blood-vessels of mammals, and are often responsible for bronchial and other disorders. The adults of the other families inhabit mainly the alimentary canal, with the exception of one small group which includes the "gape-worms" (*Syngamus*) of birds and mammals.

III. Filarioidea. Parasitic forms with paired lateral lips, or with or without secondary lip-like structures. The principal families are the Filaridae, Spiruridae, Camallanidae, Cucullanidae and Gnathostomidae.

The life-history is probably indirect in all cases. The adults of the Filariidae occur mainly in the connective tissue or blood-vessels of vertebrates, while the development of their larval stages takes place partly in mosquitoes or other blood-sucking insects, by which infection is transmitted. The Guinea-worm (*Dracunculus*) is transmitted by small water-fleas (*Cyclops*) contained in drinking-water. Among the other families the larvae usually become encapsuled in some intermediate host liable to be ingested by the final host, whose alimentary canal is the habitat of the adults.

IV. Diotrophymoidea. Containing a single family, Diotrophymidae, with three genera of parasitic forms chiefly characterized by the presence, in the male, of a caudal bursa-like structure without rays. To this group belongs *Diotrophyme*, the largest known nematode, a parasite of the urinary system of various mammals.

V. Trichinelloidea. Containing only the family Trichinellidae, parasitic forms in which the oesophagus is a cuticular tube embedded in a single chain of cells. To this group belong *Trichinella*, the cause of "trichinosis," and the "whipworms" (*Trichuris*). The life-history is usually direct, but the adults of *Trichinella*, living in the intestine, give rise to larvae which become encapsuled in the muscles of the same host, and transmission to a new host depends upon the ingestion of the flesh containing them.

Economic Importance.

Many of the nematodes parasitic in man and animals are of considerable medical and veterinary importance. Their ill effects, generally inappreciable in animals living in a state of nature, tend to become more marked in the artificial conditions under which man and his domestic animals live. Over-crowding and insanitary conditions are the chief causes of heavy infestation with such parasites, and their incidence in man is greatest in tropical and subtropical countries.

The parasites themselves may cause lesions of the tissues in various ways, or their presence may lead to secondary invasion

by pathogenic organisms of other kinds. Sometimes the presence of the worms may merely cause mechanical irritation, and so lead to inflammatory conditions. But in many cases they appear to secrete toxic substances which react detrimentally upon the host, and nervous and other disturbances, apart from local effects, may result.

Perhaps the most important of the forms occurring in man are

the hookworms (*Ancylostoma* and *Necator*), which are probably responsible, in some countries, for more disease, both physical and mental, than any other single cause. Their ravages are due in part to the ulceration of the intestine caused by their blood-sucking and tissue-destroying habits, but probably in part also to toxic properties. "Hookworm campaigns," having as one of their principal objects the education of the natives in the use of proper sanitary precautions, have been attended with considerable success in many parts of the world.

FROM RUDOLF LEUCKART, "DIE PARASITEN DER MENSCHEN"
FIG. 6.—TRICHINELLA SPIRALIS, SHOWING LARVAE ENCYSTED

Filariasis, or infestation with worms of the Filariid group, is another condition which may be of considerable importance. As has been mentioned, these worms, whose larvae circulate in the blood, and several species of which occur in man, are transmitted by mosquitoes and other blood-sucking flies. There is reason for believing that at least one of these species is concerned in the causation of elephantiasis, a terrible and disfiguring disease of wide occurrence in hot countries. Others cause tumours of the skin and other parts of the body.

Ascariasis, or infestation with Ascarids, has assumed a new importance during recent years, since it has been realized that the migrating larvae, on their passage through the lungs, are capable of inducing a form of pneumonia in their hosts when present in sufficient numbers. This is a frequent cause of death in young pigs, and deserves consideration in connection with human disease. Certain respiratory diseases in domestic animals, more especially "husk" in sheep and calves, are due to various species of lungworms (Metastrongylidae); while "gapes," a disease annually responsible for the death of large numbers of young poultry, is due to the invasion of the trachea and bronchii by a nematode (*Syngamus*). Parasitic gastritis and enteritis in cattle, sheep and horses are commonly due to nematodes, mostly belonging to the order Strongyloidea. The stomach-worm (*Haemonchus*) of sheep and cattle is one of the best known, but several others seem to be also, at times, responsible for losses.

Lastly, mention should be made of certain "free-living" forms, mainly belonging to the genera *Heterodera* and *Anguillulina* (*Tylenchus*), which are important as agricultural pests. These attack the roots, stems, leaves or ears of cultivated plants of various kinds, and may cause great deterioration or even destruction of the crops.

(H. A. B.)

NEMATOMORPHA (Gordicea or "hairworms"), a group of elongate, thread-like, unsegmented worms, probably related to the Nematoda (*q.v.*), but differing from them in certain respects. The adults occur mainly in fresh water (occasionally in wet earth), and are sometimes found in tangled masses. The species vary in length from a few inches to two or three feet, but none are thicker than whipcord. They are usually of a brownish colour.

The body-wall consists of (1) a stout cuticle, with an outer layer (smooth or with shagreen-like "areoles," sometimes bearing spines or bristles of various kinds) and an inner layer of obliquely crossed fibres; (2) a single subcuticular layer of cells; and (3) a layer of longitudinal muscle-fibres. Most of the space within the body-wall is filled with parenchymatous tissue, in which the internal organs are embedded. There is an alimentary canal, opening posteriorly into a cloaca together with the genital ducts. A

FROM SCHUTHER, "ANATOMIE ANCYLOSTOMA DUODENALE" (WM. ENGELMANN)
FIG. 5.—LATERAL VIEW OF MALE HOOKWORM (ANCYLOSTOMA)

mouth is usually absent in the adult. No circulatory or excretory organs are known. There is a single ventral nerve-cord, with anterior and posterior ganglia.

The sexes are separate, the males being usually smaller than the females and, in some genera, distinguishable by having the tail bifurcate. The tail of the female is usually undivided, but in *Paragordius* it has three prongs. The gonads are paired in both

FROM "THE CAMBRIDGE NATURAL HISTORY" (MACMILLAN)

FIGS. 1 AND 2.—GORDIID WORMS (MAGNIFIED)

1. Abdomen of a beetle (*Pterostichus niger*), with the targa removed, showing a Gordiid worm within

2. A female Gordiid worm depositing its eggs on a water plant

sexes, and are continuous with their ducts. In the gravid female the ovaries give off thin-walled lateral pockets, which ultimately break down and discharge the ova into spaces in the parenchyma. The eggs, held together by a cement-like substance, are laid in strings or masses, usually on plants or stones under water. The first larval stage is a minute creature armed with spines and having a boring organ anteriorly, by means of which it enters a host (usually an aquatic animal). In species which attack insects such as grasshoppers, the second larval stage may apparently be reached without change of host. In others it may develop in a second host, usually a beetle, which preys upon the first. The second larval stage is elongate and worm-like, and develops directly into the adult form. Pigment is developed, and the larval cuticle shed, just before emergence from the host. This usually takes place on contact with water, the worm bursting its way out through a soft place in the body-wall.

The group includes the genera *Gordius*, *Paragordius*, *Chordodes* and *Parachordodes*, to which a fifth, *Gordionus*, has been added by G. W. Müller. It is still uncertain whether *Nectonema* (a pelagic marine form provided with rows of bristles) is more closely related to this group or to the Nematoda. (H. A. B.)

NEMEA, BATTLE OF, 394 B.C. This was the decisive battle, in the sense that it broke the force of the hostile offensive, of the "Corinthian War," against Sparta, waged by the coalition of Thebes, Corinth, Athens and Argos, but instigated by Persia. In its initial pattern it was the typical frontal battle of the time, and both lines as they advanced experienced the characteristic "drift" to the right, so that each right wing overlapped the opponent's left wing. Thus on one flank the Spartans dispersed the Athenians, and on the other Sparta's allies were shattered by the Argives and Corinthians. Then, however, the Spartans, instead of pursuing blindly ahead like Clearchus and his men at Cunaxa, checked their pursuit and caught in flank three successive bodies of the enemy as they were marching back to their base. With this success the menace to Sparta waned, and the initiative in further operations passed to her. (See further CUNAXA and CORONEA.)

NEMERTINEA (NEMERTINES or NEMERTEANS), a group of unsegmented worms showing considerable resemblances to the Platyhelminthes (*q.v.*), but generally looked upon as a distinct phylum. Almost all nemertines are free-living, and the majority are marine, though a few live in fresh water or even on land. Their most characteristic feature is the possession of a remarkable eversible proboscis lying in a special sheath dorsally to the alimentary canal.

General Morphology.—In shape the body is usually elongate and cylindrical or somewhat depressed. There are no appendages, but in pelagic species certain parts of the body may be flattened out laterally to form fin-like membranes. The skin is often

brightly pigmented, brown, red, and green being the most frequent colours, while some species are conspicuously striped or banded with whitish markings, or show various other patterns. The body is completely covered with a ciliated epidermis. In or below this numerous glandular cells are usually present, which discharge their mucoid secretion on to the surface of the body. This secretion frequently forms a tube within which the animal lives. Beneath the epidermis there is a "basement membrane"

FROM "FAUNA AND FLORA" (R. FRIEDLANDER & SON)

of dense connective tissue, and below this variously arranged layers of longitudinal and circular muscle-fibres. The spaces between the individual muscle-layers, and between the musculature and the various organs of the body, are mainly filled up with connective tissue or parenchyma, and there is no true perivisceral space or coelom.

The proboscis pore (or rhynchostome) and the mouth may have a common opening at the anterior end, or the mouth may be distinct and situated subterminally on the ventral surface. There is an intestine opening posteriorly by an anus, and sometimes preceded anteriorly by a specialized oesophagus or "stomach" with muscular walls. In many species the intestine has paired lateral pouches, and an appearance of metameric segmentation is produced by the presence of a series of transverse sheets of muscular fibres stretching across the body and separating each pair of pouches from its neighbours. In certain forms there is an anterior, ventral, blind prolongation of the intestine below the "stomach." This has been shown to open in the embryo as the blastopore, and subsequently to lose its connection with the exterior.

The proboscis forms a blind invagination lying loosely within the proboscis sheath, or rhynchocoel. Its anterior portion can be everted by the contraction of the muscular walls of the sheath, and the consequent pressure of the fluid which this contains. The posterior portion is prevented from being everted by a retractor muscle attached to the wall of the rhynchocoel. The proboscis itself is generally very muscular and richly supplied with nerves. In some forms it is unarmed and probably mainly sensory in function. In others, however, it contains, in that region which becomes the anterior end in the everted condition, one or several calcareous stylets mounted on a special base, in close relation with a muscular bulb and a duct which may serve for the expulsion of a "poison."

FIG. 2.—DIAGRAM OF THE ORGANS OF A NEMERTINE

In the walls of the proboscis in armed forms, near the base of the stylet, there are two or more pockets containing "reserve" stylets. These probably take the place of the functional stylet if this is broken off, but how this occurs is unknown. In some forms the lining of the proboscis is said to contain "nematocysts" or stinging-cells like those of the coelenterates.

The central nervous system, or brain, consists of a ring surrounding the proboscis-sheath anteriorly, and developed into

lateral masses or lobes, of which there are usually two dorsal and two ventral. The brain gives off two main lateral nerve-cords which run throughout the length of the body posteriorly, and sometimes unite dorsally near the anus. It also sends a pair of large nerves to the proboscis, a pair of nerves to the sense-organs of the anterior region, and a pair to the oesophagus. There is, in many forms, a plexus of nervous tissue between the muscular layers of the body wall. In others this is absent, but the various parts and organs of the body are innervated by branches from the lateral cords. In association with the brain there is usually a pair of lateral cephalic pits or grooves, containing mucus-secreting cells and connected by ciliated canals with special masses of nervous tissue. The function of these organs is uncertain. A pair of shallow, ever-visible, lateral pits, probably sensory, also occurs farther back on the body in certain species. In many forms eyes are present, and these organs may be very numerous. They may be mere spots of dark pigment, or may be provided with a cellular lens.

There is a closed circulatory system, containing a colourless fluid and nucleated corpuscles which in some species appear to contain haemoglobin. The main vessels are three longitudinal trunks, one median and two lateral. These are connected at both ends of the body. At the anterior end, in some forms, they break up into a system of sinuses, while in others they are joined by a simple loop-like commissure. A series of metamerically arranged transverse vessels is present in many forms, connecting the three longitudinal vessels along their course.

The excretory organs, when present, usually consist of a single pair of nephridia opening laterally by ciliated ducts a little behind the mouth. Their inner ends are branched and terminate in a number of "flame-cells" closely applied to the walls of the lateral blood-vessels in the anterior region.

The sexes in the Nemertinea, with few exceptions, are separate. The gonads are constructed on a very simple plan, in strong contrast with the complicated system usually met with in the Platyhelminthes. They consist of a series of simple sacs, alternating with the lateral pouches of the intestine, and opening, when mature, by separate ducts to the exterior. The sexual products (ova or spermatozoa) are proliferated from the lining epithelium of the sacs. It is probable that the cavities of these sacs represent the coelom.

Classification.—The modern systematic arrangement of the Nemertinea is based chiefly on the armed or unarmed condition of the proboscis, the arrangement of the muscle-layers and the position of the nerve-cords. The group is divided into two subclasses and four orders, as follows:—

SUBCLASS I.—Anopla. Proboscis unarmed.

Order 1.—Palaeonemertidea. Muscle-layers two or three; usually two circular layers with a longitudinal layer between them (the inner circular layer absent in Tubulanidae). Nerve-cords external to the musculature. This order includes the families Tubulanidae, carinomidae, hubrechtidae and cephalotrichidae.

Order 2.—Heteronemertidea. Muscle-layers three; two longitudinal layers with a circular layer between them. Nerve-cords between the outer longitudinal and the circular muscles. Includes the families Baseodiscidae and Lineidae.

SUBCLASS II.—Enopla. Proboscis usually armed with one or several stylets. Muscle-layers two; an outer circular and an inner longitudinal layer. Nerve-cords internal to the musculature.

Order 3.—Malacodellidea. Body short, with a sucker at the posterior end. Proboscis unarmed, opening with the mouth. In-

testine coiled, without pouches. This order contains the leech-like form *Malacodella*, which lives as a parasite or commensal within the mantle-cavity of marine lamellibranch molluscs.

Order 4.—Hoplonemertidea. Proboscis armed. Intestine straight, with a blind, ventral, anterior diverticulum and paired lateral pouches.

Suborder 1.—Polystilifera. Stylet-base crescent-shaped, bearing several stylets along its convex side. This suborder has been divided into two "tribes," the Pelagonemertoidae and Drepanophoroidae. The former consists of pelagic forms, in which cephalic and excretory organs and an oesophagus are absent, and the male gonads are confined to the anterior region. This tribe is further subdivided into ten families (Nectonemertidae, Pelagonemertidae, etc.). The Drepanophoroidae are bottom-living forms in which cephalic and excretory organs and an oesophagus are present, and the gonads extend to the posterior end. This tribe contains the families Alboganemertidae, Uniporidae, and Drepanophoridae.

Suborder 2.—Monostilifera. Stylet-base shaped like the handle of an awl, and bearing a single terminal stylet. This suborder contains five families, of which the best known are the Amphiporidae and the Prostomatidae.

Development and Life-History.—Some nemertines go through a remarkable metamorphosis. In *Cerebratulus* there is a curious free-swimming, ciliated larval stage known as the pilidium, which resembles a helmet with side lobes like ear-lappets, and with an apical "spike" of long cilia. The pilidium is provided with an alimentary tract which is destined to become that of the fully-formed larva. Two pairs of invaginations grow inwards from the outer covering so as to surround the intestine, and ultimately form the skin and muscular body-wall of the animal. The worm is thus developed within the pilidium, which is a mere temporary envelope. It finally becomes ciliated, escapes from the pilidium, and grows into an adult. In *Lineus* there is a creeping larval form known as the "larva of Desor." This has a ciliated envelope corresponding to the pilidium, within which

FIGS. 3 AND 4.—PROBOSCIS WITH STYLET, "RESERVE" SACS AND MUSCULAR BULB OF A HOPLO-NEMERTINE

FIG. 6.—PILIDIUM-LARVA

the body of the worm is formed in a similar manner, and which is finally shed. In other forms the development is simple and direct, the pilidium stage being apparently suppressed.

The majority of nemertines live in comparatively shallow water, under stones or among algae and corals, in empty shells, or buried in mud or sand, where they frequently line their burrows with a gelatinous tube. Certain species live as commensals or possibly as parasites of other animals (crustaceans, ascidians, and molluscs). Nemertines usually progress rather slowly by crawling, though some are able to swim actively with an undulating motion. They are carnivorous and extremely voracious animals, capturing their prey with the aid of the proboscis, and being able, in many cases, to engulf creatures of considerable size, the mouth being capable of great distension.

The eggs of some species are laid in strings or masses, embedded in a gelatinous secretion. This appears to serve both as

FIG. 5.—THE ARMATURE FROM THE PROBOSCIS OF DREPANOPHORUS

a protective covering and as food material for the larvae after hatching. In some species the female secretes a definite parchment-like "cocoon" round herself before depositing her eggs. This cocoon is usually attached to a stone or weed. The body of the mother may even disintegrate after the deposition of the eggs, and form a food-supply for the young within the cocoon.

The body of many nemertines is capable of extreme extension and contraction. One common species of *Lineus* is often many yards in length when lying fully extended on a muddy bottom, and has earned the popular names of "bootlaces" and "india-rubber-worm." Another peculiarity of the group is the readiness with which many species will break themselves up into innumerable short fragments under the stimulus of any sudden irritation. Such fragments are often capable of living independently for some time, and lost portions are quickly regenerated, some or all of the pieces developing into complete worms. The proboscis, if broken off, is likewise generally reproduced. (H. A. B.)

NEMESIANUS, MARCUS AURELIUS OLYMPIUS, Roman poet, a native of Carthage, flourished about A.D. 283. He was a popular poet at the court of the Roman emperor Carus (Vopiscus, *Carus*, 11). He wrote poems on the arts of fishing (*Halieutica*), aquatics (*Nautica*) and hunting (*Cynegetica*), but only a fragment of the last, 325 hexameter lines, has been preserved. It is neatly expressed in good Latin, and was used as a school text-book in the 9th century. Four eclogues, formerly attributed to Titus Calpurnius (q.v.) Siculus, are now generally considered to be by Nemesianus, and the *Praise of Hercules*, generally printed in Claudian's works, may be by him.

Complete edition of the works attributed to him in E. Bährens, *Poetae Latini Minores*, iii. (1881) and J. P. Postgate's *Corpus Poetarum Latinorum*, ii.; see also L. Cisorio, *Studio sulle Egloghe di N.* (1895) and Dell'imitazione nelle Egloghe di N. (1896); and M. Haupt, *De Carminibus Bucolicis Calpurnii et N.* (1853), the chief treatise on the subject.

NEMESIS. (1) A goddess worshipped at Rhamnus in Attica. She is closely connected with Artemis, probably a local form of her or of some other very similar goddess. In mythology (posthomeric; the story is told in the cyclic *Cypria*) she is loved by Zeus who catches her after a transformation-race; she lays an egg, from which Helen (q.v.) is hatched out, generally by Leda (q.v.), it is a disputed point whether Leda or Nemesis is the mother of Helen in the original form of the story. There seems also to have been a legend (Catullus, lxiv., 393) that on some occasion (Marathon?) she appeared in person to encourage her worshippers in battle. (2) The indignant disapproval felt at wrong-doing; in particular, such disapproval on the part of the gods, and the consequent punishment of a sinful (or over-prosperous) man, hence (first in Hesiod) that disapproval personified. There was an old cult of "the Nemeseis" at Smyrna (Pausanias, ix., 35-36) but whether of this abstraction or of the fertility-goddess of Rhamnus, is not clear. That the abstraction was worshipped, at least in later times, is beyond doubt, however; a fragment of Antimachus (in Strabo, xiii., 1, 13) says that Adrastus was the first to erect an altar to her. In Rome especially her cult was very popular, particularly among soldiers, by whom she was worshipped as patroness of the drill-ground (*Nemesis campestris*); associated with Fortune, she seems also to have been adored as presiding over races; she had a cult-association, the *Nemesiaci*.

BIBLIOGRAPHY.—L. R. Farnell, *Cults of the Greek States*, ii. (1896); O. Rossbach in Roscher's *Lexikon*, s.v. (bibl.); G. Wissowa, *Religion und Kultus* (2nd ed., 1912).

NEMESIUS (fl. c. A.D. 390), a Christian philosopher, author of a treatise *περί φύσεως ἀνθρώπου* (*On Human Nature*), was, according to the title of his book, bishop of Emesa (in Syria). His book is an attempt to compile a system of anthropology from the standpoint of the Christian philosophy. Moses and Paul are put side by side with Aristotle and Menander, and there is a clear inclination to Platonic doctrines of pre-existence and metempsychosis. In physiology he is in advance of Aristotle and Galen, though we can hardly assert—as has sometimes been thought—that he anticipated Harvey's discovery of the circulation of the blood.

Patrol. Gr. vol. 40. Versions: Latin by Alsanus, ed. Holzinger (1887); by Burgundio, ed. Burkhardt (1891-96). Literature: Bender, *Untersuch. über Nemesius* (1898).

NEMOPHILA, a genus of North American herbs of the water-leaf family (Hydrophyllaceae), comprising some 20 species found chiefly in the Pacific coast region, 13 of which are native to California. They are more or less diffuse annuals, with parted, divided or lobed leaves, and delicate blue or white flowers, blossoming in early spring. Several are grown as border plants, especially the baby blue-eyes (*N. Menziesii*) and the five-spot (*N. maculata*). Other interesting species are the climbing nemophila or fiesta-flower (*N. aurita*), the small white nemophila (*N. heterophylla*) and the small flowered nemophila (*N. parviflora*), the last named ranging from California to Washington.

NEMORENSIS LACUS (mod. *Nemi*), a lake in the Alban hills, in an extinct subsidiary crater in the outer ring of the ancient Alban crater, east of the Lake of Albano. It is about $3\frac{1}{2}$ m. in diameter and some 110 ft. deep; the precipitous slopes of its basin are over 300 ft. high, and are mainly cultivated. In ancient times it was included in the territory of Aricia and bore the name "Mirror of Diana." The worship of Diana here was originally celebrated with human sacrifices; even in imperial times the priest of Diana was a man of low condition, a gladiator or fugitive slave, who won his position by slaying his predecessor in fight, having first plucked a mistletoe bough from the sacred grove. The temple itself was one of the richest in Latium; Octavian borrowed money from it in 31 B.C. The remains of its precinct are situated a little above the level of the lake, on the north-east—a large platform, the back of which is formed by a wall of concrete, with niches, resting against the cliffs. Excavations (now covered in again) led to the discovery of the temple itself, a comparatively small building, 98 by 52 ft., containing objects, none earlier than the 4th century B.C. A road descended to it from the Via Appia from the south-west. The lake is drained by a tunnel of about 2 m. long, of Roman date.

On the west side of the lake remains of two ships (really floating palaces moored to the shore) have been found, one belonging to the time of Caligula (as is indicated by an inscription on a lead pipe), and measuring 210 ft. long by 66 wide, the other even larger, 233 by 80 feet. The first was decorated with marbles and mosaics, and with some very fine bronze beamheads, with heads of wolves and lions having rings for hawsers in their mouths (and one of a Medusa), now in the Museo delle Terme at Rome. Various attempts have been made to raise the first ship, from the middle of the 15th century onwards, and the ancient emissarium has now been cleared in order to lay bare the remains of the ships. Caesar had a villa constructed there.

See J. G. Frazer, *The Golden Bough* (1913-14); L. Morpurgo in *Monumenti dei Lincei*, xiii. (1903), 297 sqq.

NEMOURS, LORDS AND DUKES OF. In the 12th and 13th centuries the lordship of Nemours, in Gâtinais, France, was in possession of the house of Villebeon, a member of which, Gautier, was marshal of France in the 13th century. The lordship was sold to King Philip III. in 1274 and 1276 by Jean and Philippe de Nemours, and was then made a county and given to Jean de Grailly, captal de Buch in 1364. In 1404 Charles VI. of France gave it to Charles III. of Evreux, king of Navarre, and erected it into a duchy in the peerage of France (*duché-pairie*). Charles III.'s daughter, Beatrix, brought the duchy to her husband Jacques de Bourbon, count of La Marche, and by the marriage of their daughter, Eleanor, to Bernard of Armagnac, count of Pardiac, it passed to the house of Armagnac. The duchy reverted to the French crown in 1505, after the extinction of the house of Armagnac-Pardiac. In 1507 it was given by Louis XII. successively to his nephew, Gaston de Foix (d. 1512), Guilianno de Medici and his wife Philiberta of Savoy in 1515, to Louise of Savoy in 1524, and to Philip of Savoy, count of Genevois, in 1528, whose descendants possessed the duchy until its sale to Louis XIV. In 1572 Louis gave it to his brother Philip, duke of Orleans, whose descendants possessed it until the Revolution. The title of duc de Nemours was afterwards given to Louis Charles, son of King Louis Philippe, who is dealt with separately below.

The following are the most noteworthy of the earlier dukes of Nemours.

JAMES OF ARMAGNAC, duke of Nemours (c. 1433–1477), was the son of Bernard d'Armagnac, count of Pardiac, and Eleanor of Bourbon-La Marche. As comte de Castres, he served under Charles VII. in Normandy in 1449 and 1450, and in Guienne. Louis XI. loaded him with honours, married him to his god-daughter, Louise of Anjou, and recognized his title to the duchy of Nemours in 1462. Sent by Louis to pacify Roussillon, Nemours felt that he had been insufficiently rewarded for the rapid success of this expedition, and joined the League of the Public Weal in 1465. The king's patience eventually became exhausted by his intrigues; his château at Carlat was attacked, and he was condemned by the parlement, and beheaded on Aug. 4, 1477.

See B. de Mandrot, *Jacques d'Armagnac, duc de Nemours* (1890).

CHARLES EMMANUEL (1567–1595), son of James, duke of Nemours and Anne of Este, widow of Francis, duke of Guise, was called in his youth prince of Genevois. Involved in political intrigues by his relationship with the Guises, he was imprisoned after the assassination of Henry, duke of Guise, and his brother the cardinal of Lorraine, in 1588, but escaped. He was governor of Paris when it was besieged by Henry IV. After quarrelling with his half-brother Charles of Lorraine, duke of Mayenne, he withdrew to his government of Lyonnais, where he endeavoured to make himself independent. He was imprisoned, however, in the château of Pierre-Encise by the archbishop of Lyons. After his escape he attacked Lyons, but was defeated owing to the intervention of the constable de Montmorency. He died at Annecy in July 1595.

His brother **HENRY** (1572–1632), called originally marquis de Saint-Sorlin, succeeded him as duke. In 1588 he took the marquisate of Saluzzo from the French for his cousin, the duke of Savoy. The princes of Guise, his half-brothers, induced him to join the League, and in 1591 he was made governor of Dauphiné. He made his submission to Henry IV. in 1596. After quarrelling with the duke of Savoy he joined the Spaniards in their war against Savoy. After peace had been proclaimed on Nov. 14, 1616, he retired to the French court. He died in 1632, and was succeeded by his eldest son, Louis, and on the death of the latter in 1641 by his second son, **CHARLES AMADEUS** (1624–1652), who served in the army of Flanders in 1645, and in 1646 commanded the light cavalry at the siege of Courtrai. In 1652 he took part in the war of the Fronde, and was wounded at the Faubourg St. Antoine. On July 30, 1652, he was killed in a duel by his brother-in-law, François de Vendôme, duke of Beaufort. He had two daughters, Marie Jeanne Baptiste (d. 1724), who married Charles Emmanuel of Savoy in 1665; and Marie Françoise Elisabeth, who married Alphonso VI., king of Portugal, in 1666. His brother Henry (1625–1659), archbishop of Reims, withdrew from orders and succeeded to the title.

In 1657 Henry married **MARIE D'ORLEANS-LONGUEVILLE** (1625–1707), daughter of Henry II. of Orléans, duke of Longueville. This duchess of Nemours is a famous personage. At an early age she was involved in the first Fronde, which was directed by her father and her stepmother, Anne Geneviève de Bourbon-Condé, the celebrated duchesse de Longueville; and when her husband died in 1659, leaving her childless, her life was mainly spent in contesting her inheritance with her stepmother. She left some interesting *Mémoires*, which are published by C. B. Petitot in the *Collection complète des mémoires* (1819–1829).

NEMOURS, LOUIS CHARLES PHILIPPE RAPHAËL, DUC DE (1814–1896), second son of the duke of Orléans, afterwards King Louis Philippe, was born on Oct. 25, 1814. In 1830 he became a chevalier of the order of the Saint Esprit and entered the chamber of peers. As early as 1825 his name was mentioned for the throne of Greece, and in 1831 he was elected king of the Belgians, but Louis Philippe declined the honour for his son. In Feb. 1831 he accompanied the French army which entered Belgium to support the new kingdom against Holland, and took part in the siege of Antwerp. He accompanied the Algerian expeditions against the town of Constantine in the autumn of 1836, and again in 1837, taking it by assault on Oct.

13. He sailed a third time for Algeria in 1841, and served under General Bugeaud. On his return to France he became commandant of the camp of Compiègne. He had been employed on missions to England in 1835, 1838 and 1845, and to Berlin and Vienna in 1836. His marriage in 1840 with Victoria, daughter of Duke Ferdinand of Saxe-Coburg, was marked by a check to Louis Philippe's government in the form of a refusal to bestow the marriage dowry proposed by Thiers in the chamber of deputies. The death of his elder brother, Ferdinand, duke of Orleans, in 1842 gave him a position of greater importance as the natural regent in the case of the accession of his nephew, the young count of Paris, but he was not popular. On the outbreak of the revolution of 1848 he held the Tuileries long enough to cover the king's retreat, but took no active measures against the mob. He followed his sister-in-law, the duchess of Orléans, and her two sons to the chamber of deputies, but was separated from them by the rioters, and only escaped in the uniform of a national guard. He then settled with his parents in England. His chief aim was a reconciliation between the two branches of the house of Bourbon, as indispensable to the re-establishment of the French monarchy in any form. These wishes were frustrated on the one hand by the attitude of the comte de Chambord, and on the other by the determination of the duchess of Orléans to maintain the pretensions of the count of Paris. Lengthy negotiations ended in 1857 with a letter, written by Nemours, in which he insisted that Chambord should adhere to the tricolour flag and to the principles of constitutional government.

Nemours had lived at Bushey House after the death of Queen Marie Amélie in 1866. In 1871 the exile imposed on the French princes was withdrawn, but he only returned to Paris after their disabilities were also removed. In March 1872 he was restored to his rank in the army as general of division, and placed in the first section of the general staff. In 1881 new decrees against the princes of the blood led to his withdrawal from Parisian society. He died at Versailles on June 26, 1896, the duchess having died at Claremont on Nov. 10, 1857.

See R. Bazin, *Le Duc de Nemours* (1907); Paul Thureau-Dangin, *Histoire de la monarchie de juillet* (4 vols., 1884, etc.).

NEMOURS, a town of France, in the department of Seine-et-Marne, on the Loing and its canal, 26 m. S. of Melun, by rail. Pop. (1926) 4,801. Nemours derives its name from the woods (*nemora*) in which it formerly stood, and discoveries of Gallo-Roman remains indicate its early origin. It derives its historical importance from the lordship of Nemours.

NENADOVIĆ, MATEYA (1777–1854), Serbian patriot, was born in 1777. He is generally called Prota Mateya, since as a boy of 16 he was made a priest, and a few years later became archpriest (Prota) of Valjevo. His father, Alexa Nenadović, *Knez* (chief magistrate) of the district of Valjevo, was one of the prominent Serbs murdered by the Janissaries of the Belgrade Pashalik to intimidate the people (1804). The result, on the contrary, was a general popular rising. Prota Mateya became the deputy-commander of the insurgents of the Valjevo district, but soon exchanged this post for that of chief diplomatic envoy of the insurgents. In the years 1814–15 he visited Vienna to plead the cause of Serbia to the Congress. Prota Mateya's memoirs are the most valuable authority for the history of the first and second Serbian wars of independence. The best edition is that of the Serbian Literary Association in Belgrade (1893).

NENAGH, a town of co. Tipperary, Ireland, near the River Nenagh, 96½ m. S.W. from Dublin by the Ballybrophy and Limerick branch of the Great Southern railway. Pop. (1926) 4,517. Of the old castle, Nenagh Round, dating from King John, there still exists the circular donjon or keep. There are no remains of the hospital founded in 1200 for Austin canons, nor of the Franciscan friary, founded in the reign of Henry III. Nenagh was one of the ancient manors of the Butlers, who received for it the grant of a fair from Henry VIII. In 1550 the town and friary were burned by O'Carroll. In 1641 the town was taken by Owen Roe O'Neill, but shortly afterwards it was recaptured by Lord Inchiquin. It surrendered to Ireton in 1651, and was burned by Sarsfield in 1688.

NENNIUS (fl. 796), a Welsh writer to whom we owe the *Historia Britonum*, wrote in Brecknock or Radnor. His work exists in 30 manuscripts, the earliest of which is not much earlier than the year 1000. All are defaced by interpolations which give to the work so confused a character that critics were long disposed to treat it as an unskilful forgery. A new turn was given to the controversy by Heinrich Zimmer, who, in his *Nennius vindicatus* (1893), traced the history of the work and, by a comparison of the manuscripts with the 11th-century translation of the Irish scholar, Gilla Coemgim (d. 1072), succeeded in stripping off the later accretions from the original nucleus of the *Historia*. Zimmer follows previous critics in rejecting the *Prologus maior* (§§ 1, 2), the *Capitula*, or table of contents, and part of the *Mirabilia* of the concluding section. But he proves that Nennius is the compiler of the *Historia* proper (§§ 7-65). The only part of the *Historia* which deserves to be treated as a historical document is the section known as the *Genealogiae Saxonum* (§§ 57-65). This is merely a recension of a work composed c. 679 by a Briton of Strathclyde. The author's name is unknown; but he is, after Gildas, our earliest authority for the English conquest of England. Nennius himself gives us the oldest legends relating to the victories of King Arthur; the value of the *Historia* from this point of view is admitted by the severest critics. The chief authorities whom Nennius followed were Gildas' *De excidio Britonum*, Eusebius, the *Vita Patricii* of Murichu Maccu Machtheni, the *Collectanea* of Tirechan, the *Liber occupationis* (an Irish work on the settlement of Ireland), the *Liber de sex aetatibus mundi*, the chronicle of Prosper of Aquitaine, the *Liber beati Germani*. The sources for his notices of King Arthur (§ 56) are unknown.

See J. Stevenson's edition of the *Historia Britonum* (English Hist. Soc., 1838), based on a careful study of the mss.; A. de la Borderie, *L'Historia Britonum* (Paris and London, 1883), which summarizes the older negative criticism; H. Zimmer, *Nennius vindicatus* (Berlin, 1893); T. Mommsen in *Neues Archiv der Gesellschaft für ältere deutsche Geschichtskunde*, xix. 283. (H. W. C. D.)

NEODYMIUM, the third commonest metallic element belonging to the rare-earth group (symbol Nd, atomic number 60, atomic weight 144.3), was discovered by von Welsbach in 1885 when he split "didymium" into praseodymium and neodymium. This metal occurs along with cerium, lanthanum, praseodymium, etc., in the minerals monazite, cerite, allanite, etc. It is best prepared by the fractional crystallisation of the double magnesium nitrate from water. The oxide, Nd₂O₃, is usually obtained as a light blue powder, but traces of praseodymium give it a yellow-brown tint. The oxide is rapidly dissolved by hydrochloric and nitric acids, giving amethyst solutions which show a very intense and characteristic absorption spectrum. The metal is prepared by the electrolysis of the fused anhydrous chloride, NdCl₃. It slowly oxidizes in air and is gradually attacked by cold water. It melts at 840° C. (See RARE EARTHS.) (C. J.)

NEOGNATHAE, the term now used in ornithology (*q.v.*) instead of the older term *Carinatae* (*q.v.*) to denote the section of the class Aves to which the majority of modern birds belong.

NEO-GREC, in architecture and the allied arts, a style developed in the second quarter of the 19th century in France, in which an attempt was made to instil into generally classic design a spirit at once modern, original and yet full of the restraint, delicacy and perfection of Greek details. It was largely the result of the efforts of three men—J. Duban, H. Labrousse and L. Duc. It found its most complete expression in Paris, especially in the Colonne de Juillet (1831-40) by Duc; the Library of S. Geneviève (1843-50) by Labrousse; the École des Beaux Arts (1820-39) by Duban; and the west wing of the Palais de Justice (1857-68) by Duc. The style is important, less for these complete works, than for its tremendously widespread influence throughout the middle of the 19th century, not only in Europe, but also in America. Its chief characteristics are modified orders; imaginatively modernized classic detail; much use of simple, flat surfaces, often with chamfered edges; pediment forms without horizontal cornices; and delicate, refined, incised ornament.

NEO-HEGELIANISM. For a decade or a decade and a half after 1860 the history of British and American philosophy is the story of a growing revolt against the empirical method of

John Stuart Mill and his school. The movement might have died had it not found something positive to feed upon. But it happened that a wide field of historical thought, largely unexplored by English thinkers, was there for it to turn to, namely, the German philosophy of the opening of the century, both the "criticism" of Kant and the idealistic continuation of Kantianism by Fichte, Schelling and Hegel; and "Neo-Hegelian" is the epithet attached, largely against their will, to the English group who gave the lead in this direction.

Of course no one can be prevented from using the word in other senses. Good precedent can be quoted for applying it indifferently to any revived interest in idealistic ways of thinking occurring in any country since the time of Hegel. The strongest instance in favour of an extension of meaning is the Croce-Gentile school, the most noteworthy product of contemporary thought in Italy. But on the one hand the Italian declarations of independence whenever Neo-Hegelianism is imputed to them have been so emphatic that it is hard for the historian to persist in calling them by the name; and on the other hand custom certainly sanctions the position adopted here, that Neo-Hegelianism used as a quasi-technical term is normally applied to a movement in the recent history of Anglo-Saxon thought. Perhaps the readiest conspectus of the movement will be had by treating it under two heads: its historical background and its essential teaching.

Its Historical Background.—It is important to distinguish the historical setting of the Neo-Hegelian thinkers, which is British, from the story of German thought which bulks most largely in their own account of their historical setting. The latter is a chapter in what they saw, the former yields the reason for their seeing it.

As is well known the scepticism of David Hume provoked a native Scottish reply as well as a German one. This, descending through Reid and Hamilton to Calderwood, Ferrier, Fraser and others in the 19th century set up an independent movement towards idealism which by 1860 had become pronounced especially in Scottish philosophy.

But important as it is for the historian to recognize how the Neo-Hegelian thinkers were thus provided with a reception in advance, it is even more important to consider the historical place in which they saw themselves to be standing, namely, the Kantian succession. When Kant came on the philosophical stage he found philosophy at an impasse. It was precisely the impasse to which they believed the doctrines of the empiricists Mill, Bain, Lewes, Spencer and others had brought it back. The work of Kant had been to examine the assumptions which led philosophy thither; and they held that further progress was impossible until the principle of the Kantian criticism was understood.

When Kant called attention to knowledge his interest was centred upon that which knowledge discloses, the "Nature" with which man is conversant in science and in everyday experience. There were two obvious features of it. First, its constituents were not things as they are in themselves but things as they appear to the human senses. Secondly,—and this was his problem—these appearances were not disconnected sensations. They had a certain order. They displayed themselves before us as objective. Kant asked how such objectivity was possible; and his answer consisted in saying that there was a logic of the process. The original use of the understanding whereby it arranged those appearances as an orderly world proceeded according to a logic which Kant distinguished as synthetic from the traditional formal or analytic logic, and which he called transcendental.

The idealistic successors of Kant—Fichte, Schelling and Hegel—saw in the critical philosophy a principle of reconciliation. The gulf fixed for common sense between mind and the world could be bridged. Kant had bridged it only imperfectly, leaving as he did things-in-themselves quite as much cut off from mind as the objects of common sense seemed to common sense to be. The post-Kantians sought, each in his own way, to bring the wheel full circle. Their instrument, with whatever differences, was still Kant's instrument, logic, the new "transcendental" logic, the logic of synthesis whereby the world is put together, as distinct from the formal analytic logic of the Aristotelian tradition. As

Hegel takes it over this logic has suffered two changes. It has ceased to be a mere theory of thought and become a theory of being; and it has learnt to move by dialectical procession. So reconstituted, logic emerges as an abstract version of the literal process by which the absolute spirit reveals itself as the universe, by dint of breaking forth into all the forms which the universe wears to human consciousness, nature, history, society, art, religion.

The dominion which his principle gave to Hegel over intellectual Europe at the beginning of the 19th century is one of the romances of philosophical history. There were three impressive features of him and his system. First, here was a thinker with apparently sufficient range to confront the entire field of man's then recorded experience of himself and the universe; in the second place he seemed to succeed in throwing whole territories of experience for the first time into some sort of order; and thirdly—the really remarkable circumstance—these results precipitated themselves in obedience to the assumption that the universe was the expression of spirit. It may be difficult to account for the currency of these beliefs about Hegel, but granted their currency there is nothing surprising in the impression he made.

Its Essential Teaching.—The mere existence of the Hegelian *corpus* doubtless touched the imagination of the Neo-Hegelian thinkers. It was there to show what a spiritual view of the world could be; and its presence helped to temper their disbelief in its particulars with a general belief in the possibility of "something of the kind." None of them were disciples in the way in which the original Hegelians had been. Green, more sensitive than most others to the error in some of Hegel's substantial results, even mistrusted the method by which they were obtained. To the Neo-Hegelians, Hegelianism was powerful as criticism. Green in particular was convinced by the critical regress which shows self-consciousness to be the only starting point for philosophy. He sets forth the argument in his *Prolegomena to Ethics* published posthumously in 1883 (5th ed. 1906).

This is one of the important works of the school. It is initially a constructive criticism of the empirical standpoint in ethics, its interest being to show the impossibility of either, with materialism, deriving self-consciousness from something other than itself or, with hedonism, defining the moral end by reference to something other than itself. Against the objection, almost inevitably arising, that Green is here eliminating the possibility of a logical or rational account of these matters at all, there is but one resource. It is to inquire what logic is and how far the new meaning which Kant threw into it is defensible.

Neo-Hegelianism is thus at heart a logical doctrine, and Bosanquet, whose *Logic* (1896, 2nd ed. 1911) together with Bradley's *Principles of Logic* (1883, 2nd ed. 1932) may be said to provide the technique of the whole way of thinking, expresses the spirit of it equally accurately and simply when he suggests that a colour-harmony may have logical necessity as well as a syllogism. The logic which permits such a saying is a logic of coherence. Stress upon coherence is a leading feature of Bosanquet's mind and writing. He does not, in vindicating his general position, press upon his reader the logical compulsiveness of the Kantian starting-point as Green does. He is content to exhibit the coherence which comes into our view of things when we decide to read the universe in the light of our highest experiences in it. Only in those is the coherence of the world revealed to us. And when we see how it coheres we see it as it is.

In the logical doctrine of coherence a metaphysical doctrine is involved, that of "degrees of reality." What we call our "highest" experiences occur only intermittently; and they suggest rather than express what is meant by coherence. As will, I seek the good; I rarely if ever actually find it in realizing the social will. On the other side, as intelligence, I seek the true; I shall only comparatively seldom find it in the propositions which were supremely important to my human nature as it is. None the less these rare experiences are those showing reality, giving reality in proportion as they are full and unqualified. This coincidence of reality with what man encounters when "at his fullest stretch" is the theme of the two volumes of Gifford Lectures in which

Bosanquet's long term of philosophical activity culminates, *The Principle of Individuality and Value* (1912, 2nd ed. 1927) and *The Value and Destiny of the Individual* (1913, 2nd ed. 1923).

But since man is not always at his fullest stretch, and since what he encounters and experiences in his casual moods must also be real, a doctrine of grades or degrees of reality is involved. This vital implication of Neo-Hegelianism is bared to the bone only in the metaphysical essay by F. H. Bradley, *Appearance and Reality* (1893, 8th impression, 1925) usually allowed to be the greatest work emanating from the Neo-Hegelian school.

Bradley argues for one ultimate system of experience which is reality, and shows that nothing finite is real 'taken as it stands. For reasons equally compelling, however, he must insist that the finite is real somehow. "Anything that in any sense 'is' qualifies the absolute reality and so is real." The solution of the antinomy lies in the relativity of everything finite. No exception to this law offers itself. "There is no mere appearance or utter chance or absolute error, but all is relative." The absolute or infinite experience, therefore, which logically must be, can in fact be; and so we are entitled to say that it is. The absolute is vindicated and the finite defended through the admission of degrees in truth and reality.

Bradley's essay made history both within the school and without. All three features of the finite stressed by him, the defects which condemn it, the "relativity" which suggests salvation for it and the absolute in which it is saved, have bitten into contemporary thought. For example, both his line of attack upon the finite and his line of defence have brought mathematics and physics into the idealistic argument. Apropos of his line of defence, we find the "relativity" of recent mathematical theory regarded by Viscount Haldane as a particular case of the general principle of relativity involved in the idealistic construction of experience. Apropos of his attack, we find Royce reducing all Bradley's charges against the finite to one, namely that it involves an infinite regress; and, thinking the very possibility of idealism to be at stake, he evolves a mathematical counter-argument. Besides bringing up mathematical argument in defence of idealism Bradley's dialectical attack on the finite has also provoked mathematical resistance. This has come from Russell and the realists. Curiously enough it takes exactly the same form, a defence of the finite against the charge of involving an infinite regress of a self-contradictory kind. Still deeper has been the bite of the Bradleian Absolute. Intended by him as the saviour of the finite, it has everywhere been taken as annihilating it. It has in consequence drawn upon itself almost the whole resistance of a generation, to that conception of a quiescent absolute, to which the Western mind seems constitutionally averse. Thus it generated Pragmatism in England, and played a great part in differentiating such Neo-Hegelianism as has appeared in America from the English type.

The earliest Neo-Hegelian influences which reached America found, as in England, an idealism already there, one derived largely from the same Scottish sources. There were such teachers as Noah Porter of Yale and Thomas McCosh, of Princeton. A channel through which the Neo-Hegelian interest in America found important expression was the *Journal of Philosophical Studies*, edited by W. T. Harris (1835-1909) of St. Louis (Mo.).

The note of American idealism is its solicitude for personality and the individual. This is conspicuous in Howison and still more where the influence of Lotze was stronger, as in Bowne. The feature of Royce's central work, *The World and the Individual* (1901) is its combination of a doctrine of the absolute with a doctrine of the unique individual. The substance of reality is experience, and every finite idea of which it is composed has an "internal meaning" embodying a purpose which, in the absolute, is fulfilled. The absolute is needed in order that all ideas may reach fulfilment, both those within the experience of individuals and those beyond.

Royce's absolutism can hardly be said to have survived as a school. Yet it would be untrue to say that in America the idealism which recognizes an absolute has merely disappeared, leaving its empty room to be divided between a pragmatism which emphasizes

human values and a realism which thirsts for facts. There are signs of a younger idealistic thought ambitious to vindicate the absolute realistically by touching it, so to speak, at the very nadir of fact, through the perception that all knowledge of objects is necessarily also a revelation of subject, and therefore a traffic with mind. On some such assumption seems to rest the work of W. E. Hocking (*The Meaning of God in Human Experience*, 1912), and it is possibly in a note such as this, not without its echoes on both sides of the Atlantic that the eventual issue of the Neo-Hegelian incident in the history of philosophy is to be discerned.

NEO-KANTIANISM. The philosophical movement called Neo-Kantianism commenced in Germany in the 1860's. Beginning with certain epistemological enquiries, it extended gradually over the whole field of philosophy. The individual thinkers who belong to this movement differ from each other in their interpretation of the Kantian doctrine as well as in the results which they reach from the Kantian premises. But, notwithstanding differences of detail, there is a certain methodical principle common to all of them. They all see in philosophy not merely a personal conviction, an individual view of the world, but they enquire into the possibility of *philosophy as a science* with the intention of formulating its conditions. They take their cue from the *most general* statement of the Kantian problem in the preface to the *Critique of Pure Reason* and in the *Prolegomena*. But in returning to the fundamental aim of Kant, to lead philosophy "into the safe road of a science," Neo-Kantianism finds itself confronted with a new task inasmuch as it must face a different state of science itself.

Helmholtz.—The first decisive impetus towards the reception and revival of Kant's fundamental ideas started within the circle of natural science itself. Hermann von Helmholtz' particular mentality and his significance for the development of natural science in the nineteenth century is determined by the fact that he is both a physicist and a physiologist. His main work, the *Handbuch der physiologischen Optik* (1856, 3rd ed. 1909-11), shows both methods of enquiry in their mutual interdependence and ideal union. Here the fundamental problem of Kant's *Transcendental Aesthetics*, the question of the epistemological significance of space and spatial perception, is emphatically restated. For the solution of this question, Helmholtz goes back to the researches and results of *Johannes Müller* in the field of the physiology of the senses.

In his *Vergleichende Physiologie des Gesichtssinns* (1826), Johannes Müller had developed the doctrine of the "specific energy" of sense organs; he had shown that the quality of the individual sense data,—the constitution of colour, tone, smell, etc.—is not to be explained from the constitution of the external stimulus, but from the peculiarity of the organ that conveys the sensation. This result is taken up by Helmholtz in his lecture *Ueber das Sehen des Menschen* (1855), and interpreted as an empirical confirmation of that which Kant had determined by general *a priori* considerations. The true and permanent achievement of Kantian philosophy, according to this interpretation, consists in having shown the participation of the innate laws of the mind in the formation of our ideas.

This interpretation was accepted by contemporary philosophers, especially by *Friedrich Albert Lange* (1828-1875). Lange, in his *History of Materialism* (1866), propounds as the essence of Kantian philosophy the proposition that what we call the "reality" of things is in truth nothing but their "appearance for the human species." Thus, the concept of causality, for instance, being rooted, according to this theory, in our psycho-physical organization, is prior to all experience, an *a priori* disposition of the human mind. Accordingly, it has within the field of human experience unlimited validity; but beyond this no significance whatever. By extending this interpretation to all parts of the Kantian system, Lange arrives at the conclusion that not only is the con-

cept of the "thing-in-itself" the "concept of a perfectly problematical something" having significance only as a "limiting term" (*Grenzbegriff*), but that even the "intelligible world," which was used by Kant as the foundation of *ethics*, is a "world of poetry." This poetry, to be sure, is, according to Lange, "a necessary fruit of the mind, issuing from the inner and most vital roots of the species." But in this very implication, which threatened to transform the Kantian transcendental idealism into a *fictionism* of the type developed later by *Vaihinger*, the deficiencies of the empirico-physiological interpretation of Kantian Apriorism became clearly apparent.

Zeller.—In the meantime, the attempt had already been made in German philosophy to put Kantian Apriorism on a basis broader and more solid than that which the doctrine of the specific energy of sense organs was capable of affording. In a lecture which Eduard Zeller had delivered in the year 1862 as an introduction to his course on logic and epistemology in Heidelberg, he had pointed out that epistemology formed the formal basis of philosophy as a whole, that it was epistemology "from which the final decision on the correct method in philosophy and science generally had to come." Hegel's *Wissenschaft der Logik* and his *Phaenomenologie des Geistes* had been the last grandiose attempts to comprise the whole of knowledge in its content and to develop it constructively from one unifying idea. Zeller tries to show that the attempt did not reach its goal and could not reach it, "because it overlooks the conditions of human knowledge, for it purports to grasp with one swoop from above the ideal of knowledge which, in reality, we can approach only gradually through complicated labour from below." But the magic circle of the Hegelian system—so he says—will not allow itself to be broken, so long as the presuppositions of the latter are not investigated anew and more thoroughly than before; and this very investigation necessarily leads back to Kant.

What is here expressed as a purely programmatic idea, Otto Liebmann (1840-1912) tried to carry out in his main philosophical writings. The very first of Liebmann's writings, *Kant und die Epigonen* (1865), attempts to show that the successors of Kant all missed the way which he had clearly recognized and indicated. In an intensive criticism of the "idealistic," the "realistic" and the "empirical" tendencies of post-Kantian philosophy, Liebmann tries to point out that all these movements—the systems of Fichte, Schelling and Hegel, as well as the systems of Herbart, Fries and Schopenhauer—suffer from a common fault. They all assign to the concept of the "Absolute" or of the "thing-in-itself" a central place and make it the fundamental concept of metaphysics, whereas Kant's doctrine, if rightly understood and further developed, implies the very opposite, namely, that this concept is a non-concept, that all cognition moves within the realm of mere relationships, but can never grasp or positively determine an "Absolute."

Hermann Cohen.—However, it was only in Hermann Cohen (1842-1918) that neo-Kantianism reached its climax. In his three great works on Kant: *Kants Theorie der Erfahrung* (1871, 2nd ed. 1885); *Kants Begründung der Ethik* (1877, 2nd ed. 1910); *Kants Begründung der Aesthetik* (1888), Cohen gave for the first time a critical interpretation of the entire Kantian system which, with all its penetration into the specific detail of Kant's fundamental doctrines, sets, nevertheless, one single systematic idea into the centre of the investigation. This idea is that of the "transcendental method."

From Friedrich Albert Lange, with whom Cohen was closely connected by ties of personal friendship, Cohen differs especially in that he rejects any psychological interpretation of Kant's Apriorism, any explanation of the *a priori* by the "psycho-physical organization" of man.

In his study *Das Prinzip der Infinitesimal methode und seine Geschichte* (1883), he tries to prove that the concept of the "infinitely small," as it was established in the Leibnizian differential calculus, and in the Newtonian calculus of "fluxions," is, at the same time, the indispensable and basic intellectual means for any scientific cognition of "reality." Reality is never "given" in any sense, neither in sensation nor in mere intuition, but it must

be produced by means of pure thought. The various ways and directions in which thought moves in this "production of the object" are the problems which logic has to trace.

This idea found its development in Cohen's main systematic work, the *Logik der reinen Erkenntnis* (1902, 2nd ed. 1914), to which were added, as a second and third part of his system of philosophy, the *Ethik des reinen Willens* (1904), and the *Asthetik des reinen Gefühls* (1912).

Natorp.—In closest personal and scientific contact with Cohen, Paul Natorp (1854–1924) further pursued and carried out the fundamental methodical idea of "critical idealism." For him, too, the object of knowledge is not given in itself as a ready-made thing, but "becomes" only in the eternal process of knowing, in a constantly renewed production of objects. This process never lies completed before us, as a firm and final result, an "Absolute" in the dogmatic-metaphysical meaning of the term; it is, however, possible to recognize the direction in which it moves, the general form of the production of the object. Natorp developed this main idea of his theoretical philosophy especially in his study, *Die logischen Grundlagen der exakten Wissenschaft* (1910) and in a more concentrated survey in the essay, *Philosophie, ihr Problem und ihre Probleme* (1911). Of especial importance, furthermore, is his *Allgemeine Psychologie nach kritischer Methode* (1912), which established an entirely new view of its aim and method and anticipated in decisive points Husserl's Phenomenology.

Riehl.—Cohen's insistent reference to the doctrine of Kant as the basis of all scientific philosophy and his account of the "transcendental" had a great effect even on thinkers who ultimately differed from Cohen in the conception of the critical system. Thus, for instance, the main work of Alois Riehl: *Der philosophische Kritizismus und seine Bedeutung für die positive Wissenschaft* (1876, 1879, 1887) is in its first edition still under the influence of Cohen's view of the transcendental.

Riehl, too, emphasizes that the question of the objective stock and the objective validity of knowledge should not be confounded with the question of the formation of ideas within the subjective consciousness. Kant's decisive achievement, according to Riehl, consists just in this, that he distinguished clearly the two questions, the "transcendental" and the "psychological," that he separated the problem of the objective significance of knowledge from the *genetic* question of its derivation.

But this idealism of the *general* forms of pure intuition and pure understanding constitutes, according to Riehl, only *one* phase of the Kantian doctrine, which has its counterpart in another equally legitimate and equally indispensable one. For the particulars of experience, the definite spatial and temporal order of empirical phenomena, as well as the specific causal laws subsisting between them, are never to be deduced from those general forms. Here we find ourselves necessarily referred to that other factor which Kant called the "material" factor of knowledge. The concepts of understanding as well as the pure forms of space and time give only the universal and necessary *form* of experienced reality, while its *content* can never be given to us otherwise than through *sensation*, through immediate sense-perception. Thus the latter forms the specific and indispensable basis of our conviction regarding the reality of things.

Riehl characterizes this view as "critical realism" and sees in it the specific kernel of Kant's teaching. "For the specific and definite forms of things as given in empirical intuition, that is, the position, shape, size, the definite and determinate duration and sequence of things, there must be, according to the explicit teaching of Kant, a source in the things themselves. For they cannot be derived from the universal form of intuition which originates solely in the mentality of the subject. . . . The things-in-themselves, with their proportions as expressed in the specific forms of intuition and the empirical laws of nature, are for Kant a presupposition just as essential as the *a priori* elements of cognition. The necessary combination of both, their union in experience, is the upshot of his teaching. Our knowledge of things is a mediate cognition of the things themselves through the appearances of the things to our senses" (*Zur Einführung in die Philosophie der Gegenwart*, 4th edition, 1913, p. 109f).

The Positivistic View.—Among all the thinkers of the Neo-Kantian movement, Riehl is the one who is most strongly influenced by the *positivistic* view of the nature and the task of philosophy. Scientific philosophy, in the strict sense of the word, is for him almost synonymous with pure epistemology and the methodology of the special sciences.

Hence, there remains no special field of study reserved as its proper domain; rather it is merely the texture and the logical structure of knowledge, of science itself, with which philosophic reflection can be concerned. "Instead of things, it investigates the understanding which recognizes things; instead of nature, the science of nature; instead of phenomena, their presuppositions in the consciousness of man." However, through this confinement of philosophy to the *pure science of knowledge*, Riehl ends by allowing the *theory of values* to fall out of it entirely.

To be sure, Riehl admits that there must be a "teleology of human life" for which mere knowledge of nature is not sufficient; but he himself did not study systematically the problems of this teleology, especially the ethical and aesthetic problems and the philosophy of history; he touched upon them only occasionally. "Views of the world" (*Weltanschauungen*)—so he declares explicitly—are not a matter of mere understanding; and they are for that reason subjective in the main; they do not belong to science but to *faith*. This separation of knowledge from faith carried with it the danger that scientific value was attributed to natural knowledge exclusively, while the *pure sciences of the mind* (*Geisteswissenschaften*), the sciences of the historical reality of man's mental achievements, were deprived of their specific methodical foundation.

Windelband and Rickert.—Here lies the problem from which started that tendency of Neo-Kantianism which was founded by Wilhelm Windelband and carried on by Heinrich Rickert. The epochal works of Wilhelm Dilthey (1833–1912), especially his *Einleitung in die Geisteswissenschaften* (1883), had led the attention of 19th century German philosophy back to the foundations of the historical world in the sciences of the mind. In trying to present, and to solve, this problem in the spirit of the strictly critical philosophy, it was first of all necessary to draw a sharp line between the form of science exemplified by history and that represented by natural science.

This is the task which Windelband sets himself in his address: *Geschichte und Naturwissenschaft*. The pure "sciences of laws" are here contrasted with the "sciences of events," the "nomothetic" procedure of natural science with the "ideographic" procedure of history. Rickert elaborates this distinction in his work, *Die Grenzen der naturwissenschaftlichen Begriffsbildung*, which he calls a logical introduction to the historical sciences (1896–1902, 2nd ed. 1913). In this justification, the isolated place which the pure science of knowledge had received with Riehl is abolished.

For Windelband and Rickert (*cf.* especially Rickert's *Der Gegenstand der Erkenntnis*, 1892, 2nd ed. 1904) the theory of knowledge, too, is included in the group of the *sciences of values*, because it is a science of "oughts," of the universally valid *norms* of truth. In this respect, it stands on the same level as the other studies of values, especially with ethics and aesthetics. Philosophy, as a general theory of values, as the science of the "consciousness of norms" (*Normalbewusstsein*), is essentially a philosophy of culture. Its task may be said to consist in establishing a connection between the realm of "reality" and the realm of values. It is only the concept of value that makes history possible as a science: for only through the values attached to culture can we obtain a definite principle of selection within the infinite manifold of the historical facts, and thus establish the conception of an historical individuality which is capable of description. If we now survey the path of the Neo-Kantian movement from its first beginnings to its present stage, we may say by way of summary that it has gradually encircled the total orbit of knowledge by trying to advance more and more from the "abstract" to the "concrete," from the general principles of knowledge to the specific content of mental culture. (E. Cr.)

NEOLITHIC: *see* ARCHAEOLOGY.

NEON, one of the "rare gases" of the atmosphere (*q.v.*), in which it occurs to the extent of about ten parts per million. (Symbol Ne, atomic number 10, atomic weight 20.2.) It was discovered in 1898 by Sir W. Ramsay and M. W. Travers, and has acquired publicity owing to its use for advertising signs. Of recent years it has become of great scientific importance owing to the part it has played in the investigation of isotopes (*q.v.*).

NEOPHYTE, a word used in the Eleusinian and other mysteries to designate the newly initiated, and in the early church applied to newly baptized persons. These usually wore the white garments which they received at their admission to the church (see **BAPTISM**) for eight days, from Easter eve till the Sunday after Easter (hence called *Dominica in albis*), but they were subject to strict supervision for some time longer.

NEOPLATONISM, the name given specially to the last school of pagan philosophy, which grew up mainly among the Greeks of Alexandria from the 3rd century onwards. The term has also been applied to the Italian humanists of the Renaissance, and in modern times, somewhat vaguely, to thinkers who have based their speculations on the Platonic metaphysics or on Plotinus, and incorporated with it a tendency towards a mystical explanation of ultimate phenomena.

Historical Position and Significance.—Just as the Later Roman empire was at once the supreme effort of the old world and the outcome of its exhaustion, so Neoplatonism is in one aspect the consummation, in another the collapse, of ancient philosophy. Never before in Greek or in Roman speculation had the consciousness of man's dignity and superiority to nature found such adequate expression; never before had real science and pure knowledge been so undervalued and despised by the leaders of culture as they were by the Neoplatonists.

It is a proof of the strength of the moral instincts of mankind that the only phase of culture which we can survey in all its stages from beginning to end culminated not in materialism, but in the boldest idealism. This idealism, however, is also in its way a mark of intellectual bankruptcy. Contempt for reason and science leads in the end to barbarism—its necessary consequence being the rudest superstition. As a matter of fact, barbarism did break out after the flower had fallen from Neoplatonism. The philosophers themselves, no doubt, still lived on the knowledge they repudiated; but the masses were trained to a superstition with which the Christian church, as the executor of Neoplatonism, had to reckon and contend. By a fortunate coincidence, at the very moment when this bankruptcy of the old culture must have become apparent, the stage of history was occupied by barbaric peoples. This has obscured the fact that the inner history of antiquity, ending as it did in despair of this world, must in any event have seen a recurrence of barbarism. The present world was a thing that men would neither enjoy nor master nor study. A new world was discovered, for the sake of which everything else was abandoned.

Such is Neoplatonism. The pre-Socratic philosophy took its stand on natural science, to the exclusion of ethics and religion. The systems of Plato and Aristotle sought to adjust the rival claims of physics and ethics (although the supremacy of the latter was already acknowledged); but the popular religions were thrown overboard. The post-Aristotelian philosophy in all its branches makes withdrawal from the objective world its starting-point. It might seem, indeed, that Stoicism indicates a falling off from Plato and Aristotle towards materialism, but the ethical dualism, which was the ruling tendency of the Stoa, could not long endure its materialistic physics, and took refuge in the metaphysical dualism of the Platonists. But this originated no permanent philosophical creation. From one-sided Platonism issued the various forms of scepticism, the attempt to undermine the trustworthiness of empirical knowledge. Neoplatonism, coming last, borrowed something from all the schools. First, it stands in the line of post-Aristotelian systems; it is, in fact, as a subjective philosophy, their

logical completion. Secondly, it is founded on scepticism; for it has neither interest in, nor reliance upon, empirical knowledge. Thirdly, it can justly claim the honour of Plato's name, since it expressly goes back to him for its metaphysics, directly combating those of the Stoa. Yet even on this point it learned something from the Stoics; the Neoplatonic conception of the action of the Deity on the world and of the essence and origin of matter can only be explained by reference to the dynamic pantheism of the Stoa. Fourthly, the study of Aristotle also exercised an influence on Neoplatonism. This appears not only in its philosophical method, but also—though less prominently—in its metaphysics. And, fifthly, Neoplatonism adopted the ethics of Stoicism; although it was found necessary to supplement them by a still higher conception of the functions of the spirit. Philosophy as represented by Neoplatonism, its sole interest being a religious interest, and its highest object the supra-rational, must be a philosophy of revelation.

This is not a prominent feature in Plotinus or his immediate disciples, who still exhibit full confidence in the subjective pre-suppositions of their philosophy. But the later adherents of the school did not possess this confidence; they based their philosophy on revelations of the Deity, and they found these in the religious traditions and rites of all nations. The Stoics had taught them to overstep the political boundaries of states and nationalities, and rise from the Hellenic to a universal human consciousness. Through all history the spirit of God has breathed; everywhere we discover the traces of His revelation. The older any religious tradition or mode of worship is, the more venerable is it, the richer in divine ideas. Hence the religions of the East had a peculiar interest for the Neoplatonist. Neoplatonism seizes on the aspiration of the human soul after a higher life, and treats this psychological fact as the key to the interpretation of the universe. Hence the existing religions, after being refined and spiritualized, were made the basis of philosophy.

Neoplatonism thus represents a stage in the history of religion; indeed this is precisely where its historical importance lies. In the progress of science and enlightenment it has no positive significance, except as a necessary transition which the race had to make in order to get rid of nature-religion, and that under-valuing of the spiritual life which formed an insuperable obstacle to the advance of human knowledge. Neoplatonism, however, failed as signally in its religious enterprise as it did in its philosophical. While seeking to perfect ancient philosophy, it really extinguished it; and in like manner its attempted reconstruction of ancient religions only resulted in their destruction. For in requiring these religions to impart certain prescribed religious truths, and to inculcate the highest moral tone, it burdened them with problems to which they were unequal. And further, by inviting them to loosen, though not exactly to dissolve, their political allegiance—the very thing that gave them stability—it removed the foundation on which they rested.

There is one other question which we are called upon to raise here. Why did not Neoplatonism set up an independent religious community? Why did it not provide for its mixed multitude of divinities by founding a universal church, in which all the gods of all nations might be worshipped along with the one ineffable Deity? The answer to this question involves the answer to another—Why was Neoplatonism defeated by Christianity? Three things were wanting in Neoplatonism; they are admirably indicated in Augustine's *Confessions* (vii. 18-21). First, and chiefly, it lacked a religious founder; second, it could not tell how the state of inward peace and blessedness could become permanent; third, it had no means to win those who were not endowed with the speculative faculty. The philosophical discipline which it recommended for the attainment of the highest good was beyond the reach of the masses; and the way by which the masses could attain the highest good was a secret unknown to Neoplatonism.

Yet the influence of Neoplatonism on the history of our ethical culture is immeasurable, above all because it begot the consciousness that the only blessedness which can satisfy the heart must be sought higher even than the sphere of reason. That man shall not live by bread alone, the world had learned before Neoplaton-

nism; but Neoplatonism enforced the deeper truth—a truth which the older philosophy had missed—that man shall not live by knowledge alone.

Origin.—As forerunners of Neoplatonism we may regard, on the one hand, those Stoics who accepted the Platonic distinction between the sensible world and the intelligible, and, on the other hand, the so-called Neopythagoreans and religious philosophers like Plutarch of Chaeronea and especially Numenius of Apamea. The Jewish and Christian thinkers of the first two centuries approach considerably nearer than Numenius to the later Neoplatonism. Here we have Philo, to begin with. Philo, who translated the Old Testament religion into the terms of Hellenic thought, holds as an inference from his theory of revelation that the divine Supreme Being is "supra-rational," that He can be reached only through "ecstasy," and that the oracles of God supply the material of moral and religious knowledge. The religious ethics of Philo—a compound of Stoic, Platonic and Neopythagorean elements—already bear the peculiar stamp which we recognize in Neoplatonism. While his system assigns the supremacy to Greek philosophy over the national religion of Israel, it exacts from the former, as a sort of tribute to the latter, the recognition of the elevation of God above the province of reason. The claim of positive religion to be something more than the intellectual apprehension of the reason in the universe is thus acknowledged. Religious syncretism is also a feature of Philo's system, but it differs essentially from what we find in later Neoplatonism. For Philo pays no respect to any cultus except the Jewish; and he believed that all the fragments of truth to be found amongst Greeks and Romans had been borrowed from the books of Moses. The earliest Christian philosophers, particularly Justin and Athenagoras, likewise prepared the way for the speculations of the Neoplatonists—partly by their attempts to connect Christianity with Stoicism and Platonism, partly by their ambition to exhibit Christianity as "hyperplatonic." In the introduction to his *Dialogue with Trypho*, Justin follows a method which bears a striking resemblance to the later method of Neoplatonism: he seeks to base the Christian knowledge of God—that is, the knowledge of the truth—on Platonism, Scepticism and "Revelation." A still more remarkable parallel to the later Neoplatonism is afforded by the Christian Gnostics of Alexandria, especially Valentinus and the followers of Basilides. Like the Neoplatonists, the Basilidians believed, not in an emanation from the Godhead, but in a dynamic manifestation of its activity. The same is true of Valentinus, who also placed an unnameable being at the apex of his system, and regarded matter, not as a second principle, but as a product of the one divine principle.

But were the oldest Neoplatonists really acquainted with the speculations of Philo, or Justin, or Valentinus, or Basilides? Did they know the Oriental religions, Judaism and Christianity in particular? And, if so, did they really derive anything from these sources?

To these questions we cannot give definite answers. Since Neoplatonism originated in Alexandria, where Oriental modes of worship were accessible to every one, and since the Jewish philosophy had also taken its place in the literary circles of Alexandria, we may safely assume that even the earliest of the Neoplatonists possessed an acquaintance with Judaism and Christianity. But if we search Plotinus for evidence of any actual influence of Jewish and Christian philosophy, we shall search in vain. We have to come down to Iamblichus and his school before we find complete correspondence with the Christian Gnosticism of the 2nd century; that is to say, it is only in the 4th century that Greek philosophy in its proper development reaches the stage at which certain Greek philosophers who had embraced Christianity had arrived in the 2nd century. The influence of Christianity—whether Gnostic or Catholic—on Neoplatonism was at no time very considerable, although individual Neoplatonists, after Amelius, used Christian texts as oracles, and put on record their admiration for Christ.

History and Doctrines.—The founder of the Neoplatonic school in Alexandria is supposed to have been Ammonius Saccas (q.v.). But the *Enneads* of his pupil Plotinus are the primary and classical document of Neoplatonism. The doctrine of Plotinus

is mysticism, and like all mysticism it consists of two main divisions. The first or theoretical part deals with the high origin of the human soul, and shows how it has departed from its first estate. In the second or practical part the way is pointed out by which the soul may again return to the Eternal and Supreme. Since the soul in its longings reaches forth beyond all sensible things, beyond the world of ideas even, it follows that the highest being must be something supra-rational. The system thus embraces three heads—(1) the primeval Being, (2) the ideal world and the soul, (3) the phenomenal world.

The primeval Being is, as opposed to the many, the One; as opposed to the finite, the Infinite, the unlimited. It is the source of all life, and therefore absolute causality and the only real existence. It is, moreover, the Good, in so far as all finite things have their purpose in it, and ought to flow back to it. But one cannot attach moral attributes to the original Being itself, because these would imply limitation. It has no attributes of any kind; it is being without magnitude, without life, without thought; in strict propriety, indeed, we ought not to speak of it as existing; it is "above existence," "above goodness." It is also active force without a substratum; as active force the primeval Being is perpetually producing something else, without alteration, or motion, or diminution of itself. This production is not a physical process, but an emission of force; and, since the product has real existence only in virtue of the original existence working in it, Neoplatonism may be described as a species of dynamic pantheism. Directly or indirectly, everything is brought forth by the "One."

The original Being first of all throws out the *nous*, which is a perfect image of the One and the archetype of all existing things. It is at once being and thought, ideal world and idea. As image; the *nous* corresponds perfectly to the One, but as derived it is entirely different. What Plotinus understands by the *nous* is the highest sphere accessible to the human mind, and, along with that, pure thought itself.

The image and product of the motionless *nous* is the soul, which, according to Plotinus is, like the *nous*, immaterial. Its relation to the *nous* is the same as that of the *nous* to the One. It stands between the *nous* and the phenomenal world, is permeated and illuminated by the former, but is also in contact with the latter. The *nous* is indivisible; the soul may preserve its unity and remain in the *nous*, but at the same time it has the power of uniting with the corporeal world and thus being disintegrated. It therefore occupies an intermediate position. As a single soul (world-soul) it belongs in essence and destination to the intelligible world; but it also embraces innumerable individual souls; and these can either submit to be ruled by the *nous*, or turn aside to the sensual and lose themselves in the finite.

The human souls which have descended into corporeality are those which have allowed themselves to be ensnared by sensuality and overpowered by lust. They now seek to cut themselves loose from their true being; and, striving after independence, they assume a false existence. They must turn back from this; and, since they have not lost their freedom, a conversion is still possible.

Here, then, we enter upon the practical philosophy. Along the same road by which it descended the soul must retrace its steps back to the supreme Good. It must first of all return to itself. This is accomplished by the practice of virtue, which aims at likeness to God, and leads up to God. In the ethics of Plotinus all the older schemes of virtue are taken over and arranged in a graduated series. The lowest stage is that of the civil virtues, then follow the purifying, and last of all the divine virtues. The civil virtues merely adorn the life, without elevating the soul. That is the office of the purifying virtues, by which the soul is freed from sensuality and led back to itself, and thence to the *nous*. By means of ascetic observances the man becomes once more a spiritual and enduring being, free from all sin. But there is still a higher attainment; it is not enough to be sinless, one must become "God." This is reached through contemplation of the primeval Being, the One—in other words, through an ecstatic approach, the soul may see God, the fountain of life, the source of being, the origin of all good, the root of the soul. In that

moment it enjoys the highest indescribable bliss; it is as it were swallowed up of divinity, bathed in the light of eternity. Porphyry tells us that on four occasions during the six years of their intercourse Plotinus attained to this ecstatic union with God.

Such is the religious philosophy of Plotinus, and for himself personally it sufficed, without the aid of the popular religion or worship. Nevertheless he sought for points of support in these. God is certainly in the truest sense nothing but the primeval Being; but He reveals Himself in a variety of emanations and manifestations. The *nous* is a sort of second god, the *λόγοι* which are wrapped up in it are gods, the stars are gods.

Amongst his pupils, Amelius and Porphyry are the most eminent. Amelius modified the teaching of Plotinus on certain points; and he also put some value on the prologue to the Gospel of John. To Porphyry (*q.v.*) belongs the credit of having recast and popularized the system of his master Plotinus. He was not an original thinker, but a diligent student, distinguished by great learning, by a turn for historical and philological criticism, and by an earnest purpose to uproot false teaching, especially Christianity, to ennoble men and train them to goodness. The system of Porphyry is more emphatically practical and religious than that of Plotinus. The object of philosophy, according to Porphyry, is the salvation of the soul. The origin and the blame of evil are not in the body, but in the desires of the soul. Hence the strictest asceticism (abstinence from flesh, and wine, and sexual intercourse) is demanded, as well as the knowledge of God. As he advanced in life, Porphyry protested more and more earnestly against the rude faith of the common people and their immoral worship. His work *Against the Christians* was directed, not against Christ, nor against what he believed to be Christ's teaching, but against the Christians of his own day and their sacred books, which, according to Porphyry, were the work of deceivers and ignorant people. In his trenchant criticism of the origin of what passed for Christianity in his time, he spoke bitter and severe truths, which have gained for him the reputation of the most rabid and wicked of all the enemies of Christianity. His work was destroyed, it was condemned by an edict of the emperors Theodosius II. and Valentinian in the year 448, and the copious extracts which we find in Lactantius, Augustine, Jerome, Macarius Magnus and others show how profoundly he had studied the Christian writings, and how great was his talent for real historical research.

Porphyry marks the transition to a new phase of Neoplatonism, in which it becomes completely subservient to polytheism, and seeks before everything else to protect the Greek and Oriental religions from the formidable assault of Christianity. In the hands of Iamblichus (*q.v.*), the pupil of Porphyry, Neoplatonism is changed "from a philosophical theory to a theological doctrine."

The numerous followers of Iamblichus—Aedesius, Chrysanthius, Eusebius, Priscus, Sopater, Sallust, and, most famous of all, Maximus (*q.v.*), rendered little service to speculation. Some of them (Themistius in particular) are known as commentators on the older philosophers, and others as the missionaries of mysticism. The work *De mysteriis Aegyptiorum* is the best sample of the views and aims of these philosophers. Their hopes rose high when Julian ascended the imperial throne (361–363). But the emperor himself lived long enough to see that his romantic policy of restoration was to leave no results; and after his early death all hope of extinguishing Christianity was abandoned.

But undoubtedly the victory of Christianity in the age of Valentinian and Theodosius had a purifying influence on Neoplatonism. During the struggle for supremacy, the philosophers had been driven to make common cause with everything that was hostile to Christianity. But now Neoplatonism was thrust from the great stage of history. The church and church theology, to whose guidance the masses now surrendered themselves, took in along with them their superstition, their polytheism, their magic, their myths, and all the machinery of religious witchcraft. The more all this settled and established itself—certainly not without opposition—in the church the purer did Neoplatonism become. While maintaining intact its religious attitude and its theory of knowledge, it returned with new zest to scientific studies, especially the study of the old philosophers. If Plato still remains

the divine philosopher, yet we can perceive that after the year 400 the writings of Aristotle are increasingly read and valued. In the chief cities of the empire Neoplatonic schools flourished till the beginning of the 5th century; during this period, indeed, they were the training-schools of Christian theologians. At Alexandria the noble Hypatia (*q.v.*) taught, to whose memory her impassioned disciple Synesius, afterwards a bishop, reared a splendid monument. But after the beginning of the 5th century the fanaticism of the church could no longer endure the presence of "heathenism." The murder of Hypatia was the death of philosophy in Alexandria, although the school there maintained a lingering existence till the middle of the 6th century. But there was one city of the East which, lying apart from the crowded highways of the world, had sunk to a mere provincial town, and yet possessed associations which the church of the 5th century felt herself powerless to eradicate. In Athens a Neoplatonic school still flourished.

The most distinguished teachers at Athens were Plutarch (*q.v.*), his disciple Syrianus (who did important work as a commentator on Plato and Aristotle, and further deserves mention for his vigorous defence of the freedom of the will), but above all Proclus (411–485). Proclus is the great schoolman of Neoplatonism. Forty-four years after the death of Proclus the school of Athens was closed by Justinian (A.D. 529); but it had already fulfilled its mission in the work of Proclus. The works of Proclus, as the last testament of Hellenism to the church and the middle ages, exerted an incalculable influence on the next thousand years. They not only formed one of the bridges by which the mediaeval thinkers got back to Plato and Aristotle; they determined the scientific method of thirty generations, and they partly created and partly nourished the Christian mysticism of the middle ages.

The disciples of Proclus are not eminent (Marinus, Asclepiodotus, Ammonius, Zenodotus, Isidorus, Hegias, Damascius). The last president of the Athenian school was Damascius (*q.v.*). When Justinian issued the edict for the suppression of the school, Damascius along with Simplicius (the painstaking commentator on Aristotle) and five other Neoplatonists set out to make a home in Persia. They found the conditions were unfavourable and were allowed to return (*see* CHOSROES I.).

At the beginning of the 6th century Neoplatonism had ceased to exist in the East as an independent philosophy. Almost at the same time, however—and the coincidence is not accidental—it made new conquests in the church theology through the writings of the pseudo-Dionysius. It began to bear fruit in Christian mysticism, and to diffuse a new magical leaven through the worship of the church.

In the West, where philosophical efforts of any kind had been very rare since the 2nd century, and where mystical contemplation did not meet with the necessary conditions, Neoplatonism found a congenial soil only in isolated individuals. C. Marius Victorinus (*q.v.*) translated certain works of Plotinus, and thus had a decisive influence on the spiritual history of Augustine (*Confess.* vii. 9, viii. 2). It may be said that Neoplatonism influenced the West only through the medium of the church theology, or, in some instances, under that disguise. Even Boetius (it may now be considered certain) was a catholic Christian, although his whole mode of thought was certainly Neoplatonic (*see* BOETIUS).

Neoplatonism and the Theology of the Church.—The question as to the influence of Neoplatonism on the development of Christianity is not easily answered, because it is scarcely possible to get a complete view of their mutual relations. The answer will depend, in the first instance, upon how much is included under the term "Neoplatonism." If Neoplatonism is understood in the widest sense, as the highest and fittest expression of the religious movements at work in the Graeco-Roman empire from the 2nd to the 5th century, then it may be regarded as the twin-sister of the church dogmatic which grew up during the same period; the younger sister was brought up by the elder, then rebelled against her and at last tyrannized over her. In so far as Neoplatonism and the church dogmatic set out from the felt need of redemption, in so far as both sought to deliver the soul from sensuality and recognized man's inability without divine

aid—without a revelation—to attain salvation and a sure knowledge of the truth, they are at once most intimately related and at the same time mutually independent. It must be confessed that when Christianity began to project a theology it was already deeply impregnated by Hellenic influences. But the influence is to be traced not so much to philosophy as to the general culture of the time, and the whole set of conditions under which spiritual life was manifested. When Neoplatonism appeared, the Christian church had already laid down the main positions of her theology; or if not, she worked them out alongside of Neoplatonism—that is not a mere accident—but still independently. It was only by identifying itself with the whole history of Greek philosophy, or by figuring as pure Platonism restored, that Neoplatonism could stigmatize the church theology of Alexandria as a plagiarism from itself. These assumptions, however, were fanciful. Although our sources are unfortunately very imperfect, the theology of the church does not appear to have learned much from Neoplatonism in the 3rd century—partly because the latter had not yet reached the form in which its doctrines could be accepted by the church dogmatic, and partly because theology was otherwise occupied. Her first business was to plant herself firmly on her own territory, to make good her position and clear away old and objectionable opinions. Origen was quite as independent a thinker as Plotinus; only, they both drew on the same tradition. From the 4th century downwards, however, the influence of Neoplatonism on the Oriental theologians was of the utmost importance. The church gradually expressed her most peculiar convictions in dogmas, which were formulated by philosophical methods, but were irreconcilable with Neoplatonism (the Christological dogmas); and the further this process went the more unrestrainedly did theologians resign themselves to the influence of Neoplatonism on all other questions. The doctrines of the incarnation, the resurrection of the flesh and the creation of the world in time marked the boundary line between the church's dogmatic and Neoplatonism; in every other respect, theologians and Neoplatonists drew so closely together that many of them are completely at one. In fact, there were special cases, like that of Synesius, in which a speculative reconstruction of distinctively Christian doctrines by Christian men was winked at. If a book does not happen to touch on any of the above-mentioned doctrines, it may often be doubtful whether the writer is a Christian or a Neoplatonist. In ethical precepts, in directions for right living (that is, asceticism), the two systems approximate more and more closely. But it was here that Neoplatonism finally celebrated its greatest triumph. It indoctrinated the church with all its mysticism, its mystic exercises and even its magical cultus as taught by Iamblichus. The works of the pseudo-Dionysius contain a gnosis in which, by means of the teaching of Iamblichus and Proclus, the church's theology is turned into a scholastic mysticism with directions on matters of practice and ritual. And as these writings were attributed to Dionysius, the disciple of the apostles, the scholastic mysticism which they unfold was regarded as an apostolic, not to say a divine, science. The influence exercised by these writings, first on the East, and then—after the 9th (or 12th) century—on the West, cannot be overestimated. It is impossible to enlarge upon it here; suffice it to say that the mystical and pietistic devotion of our own day, even in the Protestant churches, is nourished on works whose ancestry can be traced, through a series of intermediate links, to the writings of the pseudo-Areopagite.

In the ancient world there was only one Western theologian who came directly under the influence of Neoplatonism; but that one is Augustine, the most important of them all. It was through Neoplatonism that Augustine got rid of scepticism and the last dregs of Manichaeism. In the seventh book of his *Confessions* he has recorded how much he owed to the perusal of Neoplatonic works. On all the cardinal doctrines—God, matter, the relation of God to the world, freedom and evil—Augustine retained the impress of Neoplatonism; at the same time he is the theologian of antiquity who most clearly perceived and most fully stated wherein Neoplatonism and Christianity differ. The best ever written by any church father on this subject is to be found in chaps. ix.-xxi. of the seventh book of the *Confessions*.

Why Neoplatonism succumbed in the conflict with Christianity is a question which the historians have never satisfactorily answered. As a rule, the problem is not even stated correctly. We have nothing to do here with our own private ideal of Christianity, but solely with catholic Christianity and catholic theology. These are the forces that conquered Neoplatonism, after assimilating nearly everything that it contained. Further, we must consider the arena in which the victory was won. The battlefield was the empire of Constantine and Theodosius. It is only when these and all other circumstances of the case are duly realized that we have a right to inquire how much the essential doctrines of Christianity contributed to the victory, and what share must be assigned to the organization of the church.

In mediaeval theology and philosophy mysticism appears as the powerful opponent of rationalistic dogmatism. The empirical science of the Renaissance and the two following centuries was itself a new development of Platonism and Neoplatonism, as opposed to rationalistic dogmatism, with its contempt for experience. Magic, astrology and alchemy—all the outgrowth of Neoplatonism—gave the first effectual stimulus to the observation of nature, and consequently to natural science, and in this way finally extinguished barren rationalism. Thus in the history of science Neoplatonism has played a part and rendered services of which Plotinus or Iamblichus or Proclus never dreamt. So true is it that sober history is often stranger and more capricious than all the marvels of legend and romance.

NEOPTOLEMUS (also called PYRRHUS), in Greek legend, the son of Achilles (*q.v.*) and Deïdameia. He was brought up by his grandfather Lycomedes in the island of Scyros, and taken to Troy in the last year of the war by Odysseus, since Helenus had declared that the city could not be captured without the aid of a descendant of Aeacus. He distinguished himself by his valour and took part in the capture, slaying Priam. He was the ancestor of the Molossian kings, who therefore claimed to be of pure Hellenic stock. He was murdered by Orestes at Delphi, where he was buried, and a festival held in his honour every 8th year.

NEOPYTHAGOREANISM, a Graeco-Alexandrian school of philosophy, which became prominent in the 1st century A.D. Very little is known about the members of this school, and there has been much discussion as to whether the Pythagorean literature which was widely published at the time in Alexandria was the original work of 1st-century writers or merely reproductions of and commentaries on the older Pythagorean writings. The only well-known members of the school were Apollonius of Tyana and Moderatus of Gades. In the previous century Cicero's learned friend P. Nigidius Figulus (d. 45 B.C.) had made an attempt to revive Pythagorean doctrines, but he cannot be described as a member of the school. Further, it is necessary to distinguish from the Neopythagoreans a number of Eclectic Platonists, who, during the 1st century of our era, maintained views which had a similar tendency (e.g. Apuleius of Madaura, Plutarch of Chaeronea and, later, Numenius of Apamea).

Neopythagoreanism was the first product of an age in which abstract philosophy had begun to pall. The Stoics discovered that their "perfect man" was not to be found in the luxurious, often morbid society of the Graeco-Roman world; that something more than dialectic ethics was needed to reawaken a sense of responsibility. A degenerate society cared nothing for syllogisms grown threadbare by repetition. Neopythagoreanism was an attempt to introduce a religious element into pagan philosophy in place of what had come to be regarded as an arid formalism. The founders of the school sought to invest their doctrines with the halo of tradition by ascribing them to Pythagoras and Plato, and there is no reason to accuse them of insincerity. They went back to the later period of Plato's thought, the period when Plato endeavoured to combine his doctrine of Ideas with the Pythag-

orean number-theory, and identified the *Good* with the *One*, the source of the duality of the Infinite and the Measured (*τὸ ἄπειρον* and *ἑκὰς*) with the resultant *scale of realities* from the *One* down to the objects of the material world. They emphasized the fundamental distinction between the Soul and the Body. God must be worshipped spiritually by prayer and the will to be good, not in outward action. The soul must be freed from its material surrounding, the "muddy vesture of decay," by an ascetic habit of life. Bodily pleasures and all sensuous impulses must be abandoned as detrimental to the spiritual purity of the soul. God is the principle of Good; Matter the groundwork of Evil. In this system we distinguish not only the asceticism of Pythagoras and the later mysticism of Plato, but also the influence of the Orphic mysteries and of Oriental philosophy. The Ideas of Plato are no longer self-subsistent entities; they are the elements which constitute the content of spiritual activity. The Soul is no longer an appanage of *οὐσία*, it is *οὐσία* itself: the non-material universe is regarded as the sphere of mind or spirit.

Thus Neopythagoreanism is a link in the chain between the old and the new in pagan philosophy. It connects the teaching of Plato with the doctrines of Neoplatonism and brings it into line with the later Stoicism and with the ascetic system of the Essenes. A comparison between the Essenes and the Neopythagoreans shows a parallel so striking as to warrant the theory that the Essenes were profoundly influenced by Neopythagoreanism. Lastly Neopythagoreanism furnished Neoplatonism with the weapons with which pagan philosophy made its last stand against Christianity.

See PYTHAGORAS, NEOPLATONISM, ESSENES; and Zeller's *Philosophie d. Griechen*. For members of the school see APOLLONIUS OF TYANA and MODERATUS OF GADES.

NEPAL, an independent State, situated on the north-eastern frontier of India, lying between $80^{\circ} 15'$ and $88^{\circ} 10' E.$, and $26^{\circ} 20'$ and $30^{\circ} 10' N.$; area, 54,000 square miles. Its extreme length is about 525 m., and its breadth varies from 90 to 140 miles. It is bounded on the north by Tibet; on the east by Sikkim; on the south by Bengal and the United Provinces; on the west by Kumaon from which it is separated by the Kali river. Its population is locally estimated at about 5,500,000.

Physical Features.—Nepal consists physically of two distinct territories: (1) the *tarai*, or strip of level, cultivated and forest land lying along the southern border; and (2) the great mountainous tract stretching northwards to Tibet. Along the northern frontier stand many of the highest peaks of the Himalayan range, such as Dhaulagiri (26,837 ft.), Machapuchar, Gaurishankar and Yasa (24,000), Gosain Than (26,313), Mount Everest (29,002), Kinchinjunga (28,146), and numerous peaks varying from 20,000 to 24,000 feet. In clear weather this magnificent snowy range may be seen in an almost continuous line from the top of some of the lower ranges near Kathmandu. South of these are numerous parallel lower ranges, varying from 16,000 to 6,000 ft. in height, which are broken up by cross ranges.

These mountain ranges determine the course of the rivers, which are divided by the cross ranges into four groups. The first of these extends from Kumaon eastward as far as Dhaulagiri, and consists of the affluents of the Kali (Sarda), Sarju, Kurnali, Eastern Sarju and Rapti, all of which ultimately form the Gogra or Gogari, and flow into the Ganges. The second group, known to the Nepalese as the Sapt Gandaki, rises from the peaks between Dhaulagiri and Gosain Than, and unites at Tribeni Ghat to form the Gandak. The third is a group of smaller rivers draining the great valley of Nepal, the valleys of Chitlong, Banepa and Panouti, and portions of the tarai around the Churiaghati range of hills. These are the various branches of the Bara Gandak, the lesser Rapti, the Baghmata and Kumla. East of this again is the fourth group, known to the Nepalese as the Sapt Kosi, rising from the peaks between Gosain Than and Kinchinjunga, and uniting to form the Sun Kosi, which falls into the Ganges. There is thus a natural division of the country into four portions. The most western is the country of the Baisi (twenty-two) rajas, and contains the towns of Jumla, Doti and Sulliana. The second is the country of the Chaubisi (twenty-

four) rajas, and contains the towns of Malebum, Palpa, Gorkha and Nawakot. The third is the district containing Nepal proper, with the capital and many large towns. The fourth is the eastern portion of Nepal, comprising the country of the Kiratis, and many small towns, such as Dhankota, Ilam and Bijapur.

The only portion of Nepal (with the exception of some portions of the *tarai* country which lies at the foot of the hills), ever visited by Europeans is the Valley of Kathmandu, and even this can only be entered by special permission of the Nepal Government. A narrow gauge railway was opened by the Nepal Government in Feb. 1927 and now runs to Amlekhganj, 25 m. from the British Indian border at Raxaul, a small junction on the Bengal and North-West railway in the Champaran district in northern Bihar, due south of Kathmandu. The road from Raxaul to Kathmandu is 75 m., the first 50 of which lie across the alluvial plain of the tarai through a sal forest to the foot of the hills, whence the road follows the beds of rivers and across low ridges till the small hamlet of Bhimphedi is reached. Up to this point the road is practicable for wheeled traffic. Motor-cars run over it throughout the year except when abnormal rains cause breaches of the road. From Bhimphedi there is only a mountain track, which crosses two ridges (elevation about 8,000 ft.), and reaches the valley of Kathmandu some 9 m. from the city, whence a fair carriage road is available. A ropeway has been constructed from near Bhimphedi to the Kathmandu valley operated by electricity from the power station in the valley, which also supplies electric light to the city.

In and around the Nepal valley the year may be divided into the rainy, cold and hot seasons. The rains begin in June and last till October, the average fall being about 60" annually. The cold season extends from the middle of October to the middle of April. From April to the beginning of the rains is the hot season, but the thermometer seldom exceeds 90° in the shade. The mean temperature is 60° . Violent thunderstorms are common, and occasionally severe earthquakes occur.

Flora and Fauna.—The flora and fauna are very varied. Nepal may again be divided into three zones: (1) the *tarai* and lower ranges of hills up to 4,000 ft. in height; (2) the central ranges and high-lying valleys, up to 10,000 ft.; and (3) the alpine region, from 10,000 to 29,000 ft. in height.

The low alluvial land of the tarai is the granary of Nepal; but the greater portion consists of swamps, jungles and forests. Considerable stretches of land are, however, being reclaimed from year to year. The productions here are those of British India—cotton, rice, wheat, pulse, sugar-cane, tobacco, opium, indigo and some fruits and vegetables. The forests yield a magnificent supply of sal, sisu and other valuable forest trees, and acacias, mimosas, cotton tree (*Bombax*), dak (*Butea frondosa*), large bamboos, rattans, palms, and numerous ferns and orchids. On the Churiaghati range the common *Pinus longifolia* grows freely. Tea can be grown at a height of from 2,000 to 4,000 feet. The middle zone supplies rice, wheat, maize, barley, oats, ginger, turmeric, chillies, potatoes, Cucurbitaceae, pineapples and many varieties of European fruits, vegetables and flowers. The forests contain tree rhododendrons, *Pinus longifolia*, oaks, horse-chestnuts, walnuts, maples, hill bamboos, wild cherry, pear, allies of the tea plant, paper plants (*Daphne*), roses, and many other inhabitants of temperate climes, and orchids, ferns and wild flowers. In the alpine zone exist Coniferae of many kinds, junipers, yew, box, hollies, birch, dwarf rhododendrons and other alpine flora.

The fauna follows a similar distribution. In the lowest zone are found the tiger, leopard, wolf, hyena and jackal, the elephant and rhinoceros, the gaur (*Gavaeus gaurus*), gayal (*Gavaeus frontalis*) wild buffalo or arna, many species of deer, and the black bear (*Ursus labiatus*), pea-fowl, francolins, wild jungle fowl, and the smaller vultures, etc. In the middle zone the leopard, the Himalayan black bear (*Ursus tibetanus*), the wild dog, cats of many sorts, squirrels, hares, porcupines, the pangolin, and some species of deer and antelope, the larger vultures and eagles, pheasants (*Gallophasis*), *chikor*, hill partridges, etc. In the alpine zone are found the true bear (*Ursus isabellinus*, or brown bear), the yak, musk deer, wild goats and sheep, marmots, the eagle-

vulture (*Gypaetus*), the blood pheasant (*Ithaginis cruentus*), snow pheasant (*Tetraogallus himalayensis*), snow partridge (*Lerwa nivicola*), the horned pheasant (*Cerionis saiyra*), crested pheasant (*Catreus wallichi*), etc. Geese, ducks, waders of all sorts, and other migratory birds abound in the two lower zones.

Minerals.—The lowest zone abounds in fossils; and deposits of lignite, and even of true coal, are met with, the latter notably at a place south of Palpa. The middle zone is rich in limestone, marbles and minerals, such as iron, copper, zinc, lead and sulphur. Copper is found near the surface in many places, and there are remains of mines both at Markhu and in the great valley of Nepal. Mineral springs, hot and cold, are numerous. Traces of silver and gold have been found in the alpine zone.

People.—The races occupying Nepal are of mixed Mongol origin. To the north, in the higher mountains and valleys, dwell the Bhotias or Tibetans, to the west the Gurungs and Magars. The Murmis, Gorkhalis and Newars occupy the central parts, the Kiratis, Limbus and Lepchas the eastern. There are also Brahmans and Chhatris in the hills. There are other lesser tribes in the *tarai* and other malarious districts, known as Kumhas, Tharus, Manjis, etc., but generally classed together by the Nepalese as Aoulias, or dwellers in the districts where the *aoul*, a special type of malaria prevails. The Gorkhalis or Gurkhas are descendants of the Brahmans and Rajputs who were driven out of India by the Muslims, and took refuge in the western hilly lands, where they ultimately became dominant, and intermarried with the other races.

Religions and Languages.—The Bhotias, Newars, Limbus, Keratis and Lepchas are all Buddhists, but their religion has become so mixed up with Hinduism that it is now hardly recognizable. The Newars have entirely abandoned the monastic institutions of Buddhism, and have in great measure adopted the rules of caste, though these sit but lightly upon them. They burn their dead, eat the flesh of buffaloes, goats, sheep, ducks and fowls, and drink beer and spirits. The Gorkhalis, Magars and Gurungs are Hindus, but the last two are by no means strict in the observance of their religion. Where temples are so numerous (there are 2,733 shrines in the valley) priests both Hindu and Buddhist abound. The festivals too are many, and holidays incessant. The Raj Guru, or high priest, is an influential person in the State, a member of council, and has a large income from Government lands as well as from fines for offences against caste.

The various races have separate languages, or at least dialects. The Gorkhalis and western tribes use Parbatia (see PAHARI), which, unlike the other dialects, is of Sanskrit origin. The Newars have a distinct language and alphabets, of which three are known to their pandits, though only one is now in use. Their language, called Gubhaji, resembles Tibetan, but is interspersed with many Sanskrit words. The Bhotias use the Tibetan language and alphabet.

Education and Health.—There is a college at Kathmandu affiliated to the Patna university, and many schools in the valley of Nepal. This central institution has three departments, English, Sanskrit and Persian—or more correctly perhaps Urdu.

Kathmandu is a storehouse of ancient Sanskrit literature, and some of the oldest mss. in that language known to scholars have been found there. There is also a fair English library.

All families of good position have at least one *baid*, or medical man, in constant attendance, and there are also many general practitioners. There are two large central hospitals, civil and military, at Kathmandu and other smaller hospitals distributed over the country, with free beds, and provision for outdoor treatment. There is also a small hospital for the British Legation.

Towns.—There are three large towns in the Nepal valley, Kathmandu, the capital, said to contain approximately 90,000 inhabitants, and Patan and Bhatgaon about 30,000 each. The houses are from two to four storeys in height, built of brick and tiled. The windows and balconies are of wood, and many are elaborately carved. There are numerous handsome temples in all the towns, the majority of which are pagoda-shaped and built of brick, with roofs of tiles or copper, which is sometimes gilt. The streets are narrow, many of them paved with brick or stone.

Agriculture.—Military service is the main occupation of the Gorkhalis: the agriculture of the valley is carried on chiefly by the Newars. The soil varies from light micaceous sand to dense ferruginous clay. The whole valley is cultivated and irrigated where practicable, and the slopes of the hills are terraced, so that there is little grazing ground, and few sheep or cattle are kept. There are some milch cows and buffaloes, which are stall-fed or grazed in the jungles at the foot of the hills. Animals for food and sacrifice are all imported, and are consumed as fast as they are brought in. In the cold season the Bhotias bring large flocks of sheep and goats laden with bags of borax, salt and saltpetre. These are sold for food except for a few that are retained to carry back the bags. Poultry are kept and used by the Newars, especially ducks, the eggs of which are in great demand even among the orthodox Hindus. The crops grown in the valley consist of rice, wheat, pulse, murwah, maize, buckwheat, chillies, radishes, mustard, garlic, onions, ginger, turmeric, sugar-cane, potatoes, ground nuts, cucumbers and pumpkins, etc. Only foodstuffs may be grown in the valley; hence its suitability for producing tea, cotton and tobacco is unknown. These, however, are grown in other parts of the country, both in the hills and the *tarai*. Large cardamoms are extensively grown in the eastern hills, and form an important article of export. The hemp plant (*Cannabis indica*) grows wild.

Many European fruits, flowers and vegetables have been introduced and grow freely. The country is famous for its oranges and pineapples. Garden and wild flowers are sold for use as religious offerings, and for wear in the hair. Apples and pears, of English stock; apricots, peaches and plums do well; grapes grow freely, but seldom ripen before the rains begin, when they rot.

Trade and Manufacture.—All the trade and manufactures of the country are in the hands of the Newars, and a few Kashmiris and natives of India. The trade in European goods is chiefly carried on by the latter, whilst the Newars deal in corn, oil, salt, tobacco and articles of domestic manufacture. The trade with India is carried on at numerous marts along the frontier, at each of which a customs station is established, and the taxes are collected by a *thikadar* or farmer. The Newars also carry on the trade with Tibet, through a colony which has been for many years established at Lhasa, but this trade has diminished since the opening of the Lhasa-Darjeeling route. There are two principal routes to Tibet. One runs north-east from Kathmandu to the frontier station of Kuti or Nilam, crossing the Himalayan range at a height of 14,000 ft.; the other passes out of the valley at the north-west corner, and runs at first upwards along the main branch of the Gandak, crossing the Himalayas, near Kerung, at 9,000 ft. All goods on these routes are carried on men's backs, except the salt, etc., carried in bags by the Bhotia sheep and goats.

The Newars are skilful workmen. Their bricks are good, as is also their pottery. There are excellent carpenters, though the use of the large saw is still unknown, and planks are cut with chisel and mallet. Many of the wood carvings on the temples are of the highest artistic excellence. The modern coinage is struck by machinery, a regular mint having been established by Sir Jung Bahadur at Kathmandu, and since improved by his successors.

Government.—Till the fall of the Chinese Empire Nepal maintained relations with China and sent periodically an embassy with presents to Peking. The country is entirely independent as regards its foreign relations and domestic affairs. The British Envoy at the court is a purely diplomatic official. Theoretically the Government of Nepal is a despotism, and His Majesty the Maharajadhiraj or king is paramount. In practice, all the real power has long been in the hands of His Highness the Maharaja or prime minister, who is also supreme commander-in-chief. Under the prime minister there is a council, consisting of the relatives of the king, the Raj Guru, the generals, and a few other officials known as *Kajis*, *Sirdars* and *Bhards*, which is consulted on all important business, and which forms a court of appeal for disputed cases from the courts of law. There are civil and criminal courts.

The old savage legal code with its ordeals by fire and water, and its punishments by mutilation and torture was abolished by the prime minister Sir Jung Bahadur after his return from England in 1851. Treason, rebellion and desertion in war-time are punishable by death. Murder and the killing of cows are capital offences. Manslaughter and maiming of cows are punishable by imprisonment for life, and other offences against the person, property or caste by imprisonment or fine. Brahmins and women are exempt from capital punishment. Bankruptcy laws have been recently introduced. The marriage laws are peculiar. Among the Gurkhas the laws resemble those of other Hindus as regards the marriage of widows, polygamy, etc., but among the Newars every girl while still an infant is married with much ceremony to a betel fruit, which is then thrown into some sacred stream. As the fate of the fruit is unknown, a Newari is supposed never to become a widow. At the age of puberty a husband is selected, but the woman can at any moment divorce herself by placing a betel-nut under her husband's pillow. Slavery was completely abolished throughout the kingdom in 1925 by the prime minister, General Sir Chandra Shumshere Jung.

The revenue is mainly drawn from the land-tax, customs, mines, forests and monopolies. About 10% of the *tarai* lands, and 20% of the hill lands, are private property. Some lands were assigned by the Gorkhali rajas to Brahmins, soldiers and others, and these are untaxed. Others, which were the gifts of the old Newar kings, pay from 4 to 8 annas *per bigha*. A considerable revenue in the shape of royalty is obtained from mines of copper, iron, etc. The taxes on merchandise amount to from 12 to 14% on the value of the goods carried to and from British India, and from 5 to 6% on goods exported to Tibet.

Army.—The Gorkhalis are a military race. The standing army consists of about 45,000 men, in a fair state of efficiency. There is also a reserve, consisting of men who have served for a few years and taken their discharge, but can be called on again to enter the ranks. These would probably raise the strength to between 70,000 and 80,000 men. The regiments are formed on the British system, and similarly drilled and officered. Each man carries in addition to a bayonet a *kukri* or native knife. There is practically no cavalry, the country not being suited for horses. The artillery is on a larger scale, and consists nearly entirely of mountain guns. There is a large arsenal well provided with supplies of gunpowder and military stores. Rifles and ammunition are for the most part obtained from India.

In addition to its own army, Nepal supplies to the British army in India a large force of splendid soldiers. (H. WN.; X.)

HISTORY

Nepal and the somewhat similar country of Kashmir are peculiar among the Hindu states of India in possessing an historical literature. The Nepalese *Vamçāvali* professes to start from a very early period in the Satya Yuga, when the present valley was still a lake. The earlier portion of it is devoted to the Satya and Treta Yugas, and contains mythological tales and traditions having reference to various sacred localities in the country. During these two Yugas, and also the Dwapara Yuga, the *Vamçāvali* deals in round numbers of thousands of years.

In the beginning of the Kali Yuga, the Gupta dynasty is said to have been founded by Ne-Muni, from whom the country takes its name of Nepal. Lists are then given of the various dynasties, with the lengths of the reigns of the rajahs. The dynasties mentioned are the Gupta, Ahir, Kirāti, Somavanshi, Suryavanshi, Thakuri or first Rajput, Vaishya Thakuri, second Rajput and Karnataki dynasties. The country was then invaded by Mukundasena, and after his expulsion various Vaishya Thakuri dynasties are said to have held the throne for a period of 225 years. The chronology of the *Vamçāvali* up to this period is very confused and inaccurate; but the records begin to be clearer from the time of the invasion and conquest of the country by Harisinha-deva, the rajah of Simraun, 1324. He was driven from Simraun by Tughlak Shah of Delhi, but seems to have found little difficulty in the conquest of Nepal. There were only four rajahs of this Ayodhya dynasty, and then the throne was occupied by Jaya-

bhadra-Malla, a descendant of Abhaya-Malla, one of the Rajput dynasty, who reigned in the 13th century. The seventh rajah of this dynasty, Jayastithi-Malla, who reigned for 43 years (1386-1420), instituted legal codes and introduced the caste system to the Newars. In the reign of the eighth rajah, Yaksha-Malla, the kingdom was divided into four separate states—Banepa, Bhatgaon or Bhaktapur, Kantipur or Katmandu, and Lalitapur or Patan. The Malla dynasty in the other three branches continued in power up to the conquest of the country by the Gurkhas in 1768. (See GURKHA.)

The Gurkhas were driven out of their own country by the victorious Muslims, and took refuge in the hilly districts about Kumaon, whence they gradually pushed their way eastwards to Lamjung, Gurkha, Noakote, and ultimately to the valley of Nepal, which under Rajah Prithwi Narayana they finally captured. In the struggle which took place at Bhatgaon, Jayaprakasa (the rajah of Katmandu) was killed. Ranjit-Malla, the aged rajah of Bhatgaon, retired to Benares, where he died. Tej Narsinha, the rajah of Patan, died in confinement. During the latter years of the war Jayaprakasa applied to the British for assistance, and a small force, under Captain Kinloch, was sent into the *tarai* in 1705, but it was repulsed by the Gurkhas.

Prithwi Narayana died in 1774. He left two sons, Pratapasinha Sah and Bahadur Sah. The former succeeded his father, but died in 1777, leaving an infant son, Rana Bahadur Sah, and his brother, who had been in exile, returned to Nepal as regent. The mother of the infant king, however, was opposed to him, and he had again to flee to British territory, where he remained till the death of the rani, when he again became regent. In 1790 the Gurkhas invaded Tibet, and were at first successful; but they were brought into contact with the Chinese, who in 1791 sent a large force to invade Nepal. In 1792 the Chinese advanced as far as Noakote, and there dictated terms to the Nepalese. In 1791 the Gurkhas had entered into a commercial treaty with the British and Kirkpatrick was therefore despatched to Nepal, and reached Noakote in the spring of 1792, after the conclusion of peace. This embassy resulted in the ratification of another commercial treaty on March 1, 1792.

In 1795 Rana Bahadur removed his uncle, Bahadur Sah, from the regency, and two years later put him to death. From this time up to 1799 the king, who seems to have been insane, perpetrated the most barbarous outrages and his conduct became so intolerable that he was forced to abdicate in favour of his infant son, Girvan-yuddha Vikrama Sah. Rana Bahadur recovered the throne in 1804, but was assassinated in 1805.

In Oct. 1801 another treaty was signed by the British and Nepalese authorities, and a British resident was sent to the Nepalese court, but was withdrawn in 1803, from which time the Nepalese carried on a system of encroachment and outrage on the frontier, which led to a declaration of war by the British in Nov. 1814. The fortunes of war were not constant on either side, and fighting was almost continuous. A treaty was concluded in March 1816 by which the Nepalese relinquished much of their newly acquired territory and agreed to allow a British residency to be established at Katmandu. In November the rajah died and was succeeded by his infant son, Surendra Bikran Sah, General Bhimsena Thapa acting as regent.

In 1839 Bhimsena's enemies succeeded in driving him from power, and he committed suicide, or was murdered, in prison. The Kala Pandry faction then came into power, and there were frequent grave disputes with the British. In 1843 Matabar Singh, the nephew of Bhimsena, returned from exile, gained favour at court, and speedily effected the destruction of his old enemies, the Kala Pandrys, who were seized and executed in May 1843. At this time a nephew of Matabar Singh, Jung Bahadur, the eldest of a band of seven brothers, rose rapidly in the army and in favour at the court, especially with one of the ranis. On May 18, 1845, he killed his uncle, obtained, with the aid of the rani, a prominent position in the government, and soon after destroyed his enemies by what is known as the Kot massacre, on Sept. 15, 1846. From that time till the day of his death Jung Bahadur was in reality the ruler of Nepal. His old friend, the rani, was ban-

ished, and all posts of any consequence in the state were filled by Jung and his relations. In 1850 Jung Bahadur paid a visit to England, and there proved himself to be a staunch friend of the British. On his return in 1851 he devoted himself to reforming the administration of the country, and it must be allowed that he eventually proved himself the greatest benefactor his country has ever possessed. In 1853 a treaty for the extradition of criminals was proposed, and ratified in Feb. 1855. In 1854 the Nepalese commenced a war against Tibet, which ended with a peace very favourable to Nepal in March 1856.

In June 1857 intelligence of the mutiny of the native troops in Hindustan reached Nepal. Jung Bahadur, in spite of great opposition, stood firm as a friend of the British. On June 26, 4,000 troops were despatched and rendered excellent service. Jung followed on Dec. 10 with a force of 8,000 men, 500 artillerymen and 24 guns, but too late to be of much use. Many of the mutineers and rebels, including the infamous Nana Sahib, took refuge in the Nepalese tarai, and it was not till the end of 1850 that they were finally swept out of the country. Jung Bahadur was knighted and decorated for his services and his troops received pay and handsome donations if wounded. Quantities of arms were presented to the Nepalese government and some territory was restored. This ground contains most valuable sal and sisu forests, and yields yearly a revenue of several lakhs of rupees.

From the termination of the mutiny Nepalese history has been uneventful. In spite of friendly relations with the British, many of the early restrictions against entering the country and trading there are still rigidly enforced. Sir Jung Bahadur died suddenly in 1877. His brother, Sir Ranadip Singh Bahadur, G.C.S.I., succeeded him as prime minister. Shortly after his accession to power a plot was formed against him, but nearly 40 of the conspirators were seized and executed, while others escaped into exile. He was, however, murdered in 1885, and was succeeded by his nephew Sir Shamsher Jung, G.C.S.I., who died in 1901 and was succeeded by his brother Deb Shamsher Jung. In June of that year a palace revolution placed another brother, Chandra Shamsher Jung, in power, whilst Deb Shamsher fled to India. Chandra Shamsher ruled Nepal with much ability. He gave effective aid to the British during the Tibet war of 1904, and the relations with the government of India became more cordial after his accession. In 1906 Chandra Shamsher was created a G.C.S.I., and in 1908 he visited England as a guest of the Government, when he was invested with the G.C.B., and created major-general in the British army and honorary colonel of the 4th Gurkha Rifles.

During the World War, Sir Chandra Shamsher Jung placed the whole resources of his country at the disposal of the Allies. From 1915-18 some 10,000 men of the Nepalese army served in India and on the Indian frontier. The 20 Gurkha battalions of the Indian army were increased to 40. Exclusive of the Maharajah's personal numerous subscriptions to military hospitals and charitable war-funds, nearly £1,000,000 was contributed by the Nepalese government. Cardamoms, tea, blankets, and timber were also given. In the brief Afghan war (1910), 2,000 Nepalese troops assisted the Indian government. Chandra Shamsher Jung was also responsible for the abolition of slavery in Nepal.

Replacing the old Treaty of Segowlie (1815) a new treaty of friendship was signed on Dec. 21, 1923, an important provision of which is the recognition by the British Government of the complete independence of Nepal.

NEPENTHES, an Egyptian drug spoken of by Homer in the *Odyssey* (iv. 221). Generally in the form "nepenthe" the name is given to any drug producing exhilaration and also occasionally to the herb or plant from which such a drug is produced. It is also applied to an interesting genus of plants, comprising 60 species, chiefly East Indian, known as the "pitcher-plants"

on account of the formation of the leaves. Numerous varieties and artificial hybrids of several species, especially *N. ampullaria* and *N. Rafflesiana*, are grown as curiosities in hothouses.

NEPHELINE, a rock-forming mineral consisting of sodium, potassium and aluminium silicate, with the approximate formula $\text{Na}_2\text{K}_2\text{Al}_2\text{Si}_6\text{O}_{20}$. Its crystals belong to the hexagonal system, and usually have the form of a short six-sided prism terminated by the basal plane. The hardness is 5.5. The specific gravity (2.6), the low index of refraction and the feeble double refraction are nearly the same as in quartz; but since in nepheline the sign of the double refraction is negative, while in quartz it is positive, the two minerals can be distinguished under the microscope. An important determinative character of nepheline is the ease with which it is decomposed by hydrochloric acid, with separation of gelatinous silica (which may be readily stained by colouring matters) and cubes of salt. A clear crystal of nepheline when immersed in acid becomes for this reason cloudy; hence the name, from Gr. *νεφέλη*, a cloud.

Although in naturally occurring nepheline sodium and potassium are always present in approximately the atomic ratio 3 : 1, artificially prepared crystals have the composition NaAlSiO_3 ; the corresponding potassium compound, KAlSiO_3 , which is the mineral kaliophilite, has also been prepared artificially. It has therefore been suggested that the orthosilicate formula, $(\text{Na,K})\text{AlSiO}_3$, represents the true composition of nepheline, and that the excess of silica is due to the presence of albite, leucite, or silica molecules in "solid solution" in the mineral.

The mineral is specially liable to alteration, and in the laboratory various substitution products of nepheline have been prepared. In nature it is frequently altered to zeolites (especially natrolite), sodalite, kaolin, or compact muscovite. Two varieties are distinguished, differing in external appearance and mode of occurrence. "Glassy nepheline" has the form of small, colourless, transparent crystals and grains with a vitreous lustre. It is characteristic of the later volcanic rocks rich in alkalis, such as phonolite, nepheline-basalt, leucite-basalt, etc., and also of certain dike-rocks, such as tinguaita. The best crystals are those which occur with mica, sanidine, garnet, etc., in the crystal-lined cavities of the ejected blocks of Monte Somma, Vesuvius. The other variety, known as elaeolite, occurs as large, rough crystals, or more often as irregular masses, which have a greasy lustre and are opaque, or at most translucent, with a reddish, greenish, brownish or grey colour. It forms an essential constituent of certain alkaline plutonic rocks of the nepheline-syenite series, which are typically developed in southern Norway.

The colour and greasy lustre of elaeolite (Gr. *ελαίον*, oil, and *λίθος*, stone; Ger. *Fettstein*) are due to the presence of numerous microscopic enclosures of other minerals, possibly augite or hornblende. These enclosures sometimes give rise to a chatoyant effect like that of cat's-eye and cymophane; and elaeolite when of a good green or red colour and showing a distinct band of light is sometimes cut as a gem-stone with a convex surface.

NEPHELINE-SYENITE or **ELAEOLITE-SYENITE**, a holocrystalline plutonic rock which consists largely of nepheline and alkali felspar. The rocks are mostly pale coloured, grey or pink, and in general appearance they are not unlike granites, but dark green varieties are also known. They do not contain quartz, as that mineral and nepheline are mutually exclusive. From ordinary syenites they are distinguished not only by the presence of nepheline but also by the occurrence of many other minerals rich in alkalis or in rare earths. Orthoclase and albite are the principal felspars; usually they are intergrown to form perthite. In some rocks the potash felspar, in others the soda felspar predominates. Soda-lime felspar such as oligoclase and andesine are rare or entirely absent. Fresh clear microcline is very characteristic of some types of nepheline-syenite. Sodalite, colourless and transparent in the slides, but frequently pale blue in the hand specimens, is the principal feldspathoid mineral in addition to nepheline. As a rule these two crystallize before felspar, but they may occur in perthitic intergrowth with it. The commonest ferro-magnesian mineral is pale green augite, which may be surrounded by rims of dark-green, pleochroic soda-augite

(aegirine). The latter forms long flat prisms or bundles of radiating needles. A dark reddish-brown biotite is very common in some of these rocks and a white mica, probably not muscovite but lepidolite, is occasionally present. The hornblende may be brown, brownish-green, blue or blue-black, belonging as a rule to the varieties which contain soda; it is often intergrown with the pyroxene or enclosed in it. The dark-brown triclinic hornblende aenigmatite occurs also in these rocks. Olivine is rare, but may be found in some basic forms of nepheline-syenite.

The commonest accessories are sphene, zircon, iron ores and apatite. Cancrinite occurs in several nepheline-syenites; in others there is fluor-spar or melanite garnet. Small amounts of primary calcite also occur in some nepheline-syenites. A great number of interesting and rare minerals have been recorded from these rocks and the pegmatite veins which intersect them. Among these we may mention eudialyte, eukolite, mosandrite, rinkite, johnstrupite, lävenite, hiortdahlite, perofskite and lamprophyllite. Many of these contain fluorine and the rare earths.

Nepheline-syenites are rare rocks; there is only one occurrence in Great Britain and one each in France and Portugal. They are known also in Bohemia and in several places in Norway, Sweden and Finland. In America these rocks have been found in Texas, Arkansas and Massachusetts, also in Ontario, British Columbia and Brazil. South Africa, Madagascar, India, New South Wales, Tasmania, Timor and Turkestan are other localities for the rocks of this series. They exhibit also a remarkable individuality, as each occurrence has its own special features; moreover a variety of types characterizes each occurrence, as these rocks are very variable. For these reasons, together with the numerous rare minerals they contain, they have attracted a great deal of attention from petrographers.

Many types of nepheline-syenite have received designations derived from the localities in which they were discovered. The laurdalites (from Laurdal in Norway) are grey or pinkish, and in many ways closely resemble the laurvikites of southern Norway, with which they occur. The foyaïtes include the greater number of known nepheline-syenites and are called after Foya in the Serra de Monchique (southern Portugal), from which they were first described. They are grey, green or reddish, and mostly of massive structure with preponderating potash felspar, some nepheline, and a variable (often small) amount of feldspar minerals. Pyroxene-, hornblende- and biotite-foyaïtes have been recognized according to their mineral composition. Examples of the first-named occur in southern Norway with the laurdalites; they contain aegirine and black mica. At Alnö Island in the Gulf of Bothnia (Sweden) similar rocks are found bearing enclosures of altered limestone with wollastonite and scapolite. In Transylvania there is a well-known rock of this group, very rich in microcline, blue sodalite and cancrinite. It contains also orthoclase, nepheline, biotite, aegirine, acmite, etc. To this type the name ditroite has been given from the place where it occurs (Ditro). Pyroxene-foyaïte has been described also from Pouzac in the Pyrenees (S. France). Mica-foyaïte is not very common, but is known at Miask in the Ural Mountains (miaskite), where it is coarse-grained, and contains black mica, sodalite and cancrinite. Hornblende-foyaïtes occur in Brazil (Serra de Tingua) containing sodalite and often much augite, in the western Sahara and Cape Verde Islands; also at Zwarte Koppies in the Transvaal, Madagascar, São Paulo (in Brazil), Paisano Pass (West Texas) and Montreal, Canada. The rock of Salem, Mass., U.S.A., is a mica-foyaïte rich in albite and aegirine; it accompanies granite and essexite.

Litchfieldite is another well-marked type of nepheline-syenite, in which albite is the dominant felspar. It is named after Litchfield, Maine, U.S.A., where it occurs in scattered blocks. Biotite, cancrinite and sodalite are characteristic of this rock. A similar nepheline-syenite is known from Hastings Co., Ontario, and contains hardly any orthoclase, but only albite felspar. Nepheline is very abundant and there is also cancrinite, sodalite, scapolite, calcite, biotite and hornblende. The lujaïtes are distinguished from the rocks above described by their dark colour, which is due to the abundance of minerals such as augite, aegirine, arfvedsonite and

other kinds of amphibole. Typical examples are known near Lujaur on the White Sea, where they occur with umptekites and other very peculiar rocks. Other localities for this group are at Julianehaab in Greenland (with sodalite-syenite); at their margins they contain pseudomorphs after leucite. The lujaïtes frequently have a parallel banding or gneissose structure.

Sodalite-syenites in which sodalite very largely or completely takes the place of nepheline occur in Greenland, where they contain also microcline-perthite, aegirine, arfvedsonite and eudialyte. Cancrinite-syenite, with a large percentage of cancrinite, has been described from Dalekarlia (Sweden) and from Finland.

The chemical peculiarities of the nepheline-syenites are well marked, as will be seen from the following analyses. They are exceedingly rich in alkalis and in alumina (hence the abundance of feldspathoids and alkali feldspars) with silica varying from 50 to 56%, while lime, magnesia and iron are never present in great quantity, though somewhat more variable than the other components. As a group, also, these rocks have a low specific gravity.

	SiO ₂	Al ₂ O ₃	FeO	Fe ₂ O ₃	CaO	MgO	K ₂ O	Na ₂ O
Laurdalite	54.55	19.07	3.12	2.41	3.15	1.98	4.84	7.67
Ditroite	56.30	24.14	...	1.99	0.69	0.13	6.79	9.28
Litchfieldite	60.39	22.57	2.26	0.42	0.32	0.13	4.77	8.44
Lujaïte	54.14	20.61	2.08	3.28	1.85	0.83	5.25	9.87

(J. S. F.)

NEPHELINITES. The group of effusive rocks which contains nepheline with plagioclase felspar is subdivided into nepheline-tephrites and nepheline-basanites, while those which contain nepheline but not felspar are nephelinites and nepheline-basalts. The tephrites differ from the basanites in the absence of olivine, and the same distinction subsists between the nephelinites and nepheline-basalts.

Lavas with nepheline, plagioclase and augite—nepheline-tephrites; lavas with nepheline, plagioclase, augite and olivine—nepheline-basanites; lavas with nepheline and augite—nephelinites; lavas with nepheline, augite and olivine—nepheline-basalts.

In their essential and accessory minerals, appearance and structure, these rocks have much in common, and tend to occur in a natural association as basic rocks comparatively rich in alkalis and alumina. The nephelinites and tephrites are linked to the phonolites and pass into them by various gradations. They are usually richer in alkalis and silica and contain less iron, lime and magnesia than the basanites and nepheline-basalts, a difference which finds expression in the presence of olivine and the smaller amount of feldspars and feldspathoids in the latter.

Leucite appears in some tephrites; haitiïne is more frequent as small dodecahedra often filled with black inclusions. The pyroxene varies a good deal, and includes green aegirine and the purple titan-augite. It has often good crystalline form, and occurs as eight-sided monoclinic prisms. Hornblende is much less common, but biotite is very characteristic of certain nephelinites. Of the feldspars, labradorite is probably the most common, with more acid varieties of plagioclase. Sanidine is by no means absent, but may be considered as an accessory. The olivine presents no peculiarities. Melilite, perofskite, pseudobrookite, melanite garnet, iron oxides, apatite and chromite are occasionally met with.

All these rocks are practically confined to lavas of Tertiary and recent age, though some occur as dikes or small intrusive masses. The plutonic facies of these rocks are found among the theralites, shonkinites, essexites and ijolites. In the British Isles they are exceedingly scarce, though nepheline-basanite occurs in a dike which is presumably Tertiary, cutting the Triassic rocks at Butterton, Staffs., and nepheline-basalt has been found in a single neck at John o' Groat's and at one or two places near North Berwick. They attain a great development in the Canary Islands and in the Azores, Cape Verde Islands and Fernando Noronha. In Germany they are represented among the Tertiary eruptive rocks of the Rhine district and Thuringia, at the extinct craters of the Eifel and at the Kaiserstuhl. In central Bohemia there are many occurrences of nepheline-tephrites, basanites and basalts which though

fine grained contain all their minerals in excellent preservation. The nephelinite of Katzenbuckel in the Odenwald is well known. Contrasted with the phonolites and leucitophyres they are scarce in Italy and the Mediterranean province, but leucite-bearing nepheline-tephrites occur at Monte Vulture and nepheline-basalts in Tripoli. In America these rocks occur in Texas, in the Bearpaw mountains of Montana and at Cripple Creek, Colorado. From Argentina some members have been described: they have a great extension in East Africa (Somaliland and Masai-land) and occur also in North Nigeria. A few also have been described from New South Wales, New Zealand (Dunedin) and Tasmania.

(J. S. F.)

NEPHRITIS: see BRIGHT'S DISEASE; KIDNEY, DISEASES OF.
NEPOMUK or POMUK, JOHN OF, the national saint of Bohemia. It is necessary to distinguish between the John of Nepomuk of history and the legendary one. A John of Pomuk, son of a German called Wölff, was vicar-general to the archbishop of Prague, John of Jenenstein, in 1393, and having thwarted King Wenceslaus IV. of Bohemia in a plan to seize the revenues of the abbey of Kladrub, was arrested and tortured, finally being carried to the bridge of Prague and thrown into the Vltava. It is difficult to connect this historical event with the legend of St. John of Nepomuk, who was canonized by Rome in 1729, mainly through the influence of the Jesuits, who hoped that this new cult would obliterate the memory of Hus. The Austrian chronicler Thomas Ebendorffer of Haselbach, who lived two generations later, first states that it was reported that King Wenceslaus had ordered that the confessor of his queen—an office that John of Pomuk never held—should be thrown into the Vltava because he would not reveal the secret of confession. The story is afterwards told in greater detail by the untrustworthy Bohemian historian Wenceslaus Hajek. It appears certain that the person canonized in 1729 was not the historical John of Pomuk or Nepomuk.

See A. H. Wratislaw, *Life, Legend and Canonization of St. John Nepomuk* (1873), a valuable work founded on the best Bohemian authorities; also A. Frind, *Der geschichtliche Heilige Johann von Nepomuk* (1861); O. Abel, *Die Legende vom heiligen Johann von Nepomuk* (1855); and particularly vol. iii. of W. W. Tomek's *History of the Town of Prague* (Czech) (12 vols., Prague, 1855-1901).

NEPOS, CORNELIUS (c. 99-24 B.C.), Roman historian, friend of Catullus, Cicero and Atticus, was born in Upper Italy (perhaps at Verona or Ticinum). He wrote: *Chronica*, an epitome of universal history; *Exempla*, a collection of anecdotes; letters to Cicero; lives of Cato the elder and Cicero; and *De viris illustribus*, parallel lives of distinguished Romans and foreigners, in sixteen books. One section of this work (more commonly known as *Vitae excellentium imperatorum*) and the biographies of Cato and Atticus from another (*De Latinis historicis*), have been preserved. Erotic poems and a geographical treatise are also attributed to him. The *Lives* contain many errors (especially in chronology), but supply information not found elsewhere. The language is as a rule simple and correct. The *Lives* were formerly attributed to Aemilius Probus of the 4th century A.D.; but the view maintained by Lambinus (in his famous edition, 1569)—that they are all the work of Nepos—is now generally accepted. In modern times G. F. Unger (*Der sogenannte C. N.*, 1831) has attempted to prove that the author was Hyginus, but his theory has not been favourably received.

Editions of the *Lives* (especially selections) are extremely numerous; text by E. O. Winstedt (Oxford, 1904), C. L. Roth (1881), C. G. Cobet (1881), C. Halm and A. Fleckeisen (1889), with lexicon for school use; with notes, O. Browning and W. R. Inge (1888), J. C. Rolfe (U.S. 1894), A. Weidner and J. Schmidt (1902), C. Erbe (1892), C. Nipperdey and B. Lupus (ed. maj., 1879, school ed., 1895), J. Siebelis and O. Stange (1897).

NEPOS, JULIUS, emperor of the West (474-475), was the nephew and successor of Marcellinus, count of Dalmatia. Being connected by marriage with Leo I., he was selected by him as emperor after the death of Olybrius. After capturing his rival Glycerius (q.v.), he was recognized as emperor in Italy, Rome and Gaul. The only event of his reign was the cession of Auvergne to the Visigoths. Nepos was overthrown in 475 by the Patrician Orestes, and fled to Salona, where he was assassinated

(480 or 481), possibly at the instigation of Glycerius, who had been compelled to enter the Church.

NEPTUNE (*Neptunus*, Etruscan *Nethuns*). An Italian god of fresh water, associated with Salacia (? from *salire*, referring to the bubbling of springs). Not later than 399 B.C. (see Livy, v. 13, 6), he was identified with Poseidon (q.v.) and henceforth was known as a sea-god. His ancient festival (Neptunalia) was on July 23; i.e., in the heat of summer, when water is most wanted and streams are drying up. He had no temple until the 3rd century B.C., so far as we know; it was near the Circus Flaminius. In like manner Portunus, originally the god of city gates (*portae*) became god of harbours (*portus*) as Roman overseas trade became important.

See Wissowa, *Religion und Kultur*, 2nd ed., p. 225.

NEPTUNE, Ψ in astronomy, is the outermost of the known planets, its mean distance from the Sun being 2,793,500,000 miles; and the time occupied in completing a revolution is 164.8 years. It is noteworthy that "Bode's law" (see PLANET) which expresses with considerable accuracy the relative distances of the other planets from the Sun breaks down badly at Neptune, giving the value 38.8 units, whereas the actual distance is but 30.1 units. The light of Neptune being only equal to that of a star of the eighth magnitude, the planet is, of course, invisible without optical aid, but a telescope of moderate aperture will show that its image, unlike that of a star, possesses a sensible disc. This is of a greenish hue and about 2.5" in diameter, which, at the planet's distance, corresponds to some 33,000 miles. It has not been possible, however, to detect any features on its surface from which its rotation period could be derived, but from a comparison of its brightness with that of neighbouring stars Maxwell Hall in 1883, and again in 1915, found temporary periodic fluctuations suggesting rotation is about 7^h 50^m or a little more. Moore and Menzel have found by spectroscopic methods a period of 15^h 8^m ± 1^m, and, since it has been shown by Jackson and others that a period of 7^h 50^m is inconsistent with the shift in the mode of the satellite, it seems probable that the photometric value is half the true period. The spectroscopic results also indicate that the rotation of the planet is direct or in a direction contrary to that of the orbital motion of the satellite.

As regards its physical condition it is known that Neptune is similar to the other members of the outer group of planets in possessing a low density. Its mass, which is derived from the motion of its satellite, is about 16.9, and its density 0.24, the corresponding values for the earth being taken as unity.

As is the case with the other major planets Neptune is enveloped in a dense atmosphere, and its spectrum shows a number of strong absorption bands, the origin of which is not yet known. These bands show a well marked progression in intensity from Jupiter outwards through Saturn and Uranus to Neptune (see Plate, *Planets*).

Neptune's Satellite.—Neptune possesses only one moon. This was discovered by William Lassell within a month of the finding of the planet itself, and it is interesting in that it was the first of the satellites in the Solar system known to possess retrograde motion, the inclination of its orbit to the ecliptic being 145°. Its period of revolution is 5^d 21^h. The name Triton has been given to it but it is more generally known as "the satellite of Neptune."

The Discovery of Neptune.—By far the most interesting thing about Neptune is the story of its discovery. The account which follows was written by the late Professor Simon Newcomb.

The detection of Neptune through its action upon Uranus before its existence had been made known by observation is a striking example of the precision reached by the theory of the celestial motions. So many agencies were concerned in the final discovery that the whole forms one of the most interesting chapters in the history of astronomy. The planet Uranus, before its actual discovery by Sir William Herschel in 1781, had been observed as a fixed star on at least 17 other occasions, beginning with Flamsteed in 1690. In 1820 Alexis Bouvard of Paris constructed tables of the motion of Jupiter, Saturn and Uranus, based upon a discussion of observations up to that year. Using the mutual perturbations of these planets as developed by Laplace in the *Mé-*

canique Céleste, he was enabled satisfactorily to represent the observed positions of Jupiter and Saturn; but the case was entirely different with Uranus. It was found impossible to represent all the observations within admissible limits of error, the outstanding differences between theory and observation exceeding 1'. In these circumstances one of two courses had to be adopted, either to obtain the best general representation of all the observations, which would result in the tables being certainly erroneous, or to reject the older observations which might be affected with errors, and base the tables only on those made since the discovery by Herschel. A few years of observation showed that Uranus was deviating from the new tables to an extent greater than could be attributed to legitimate errors of theory of observation, and the question of the cause thus became of growing interest. Among the investigators of the question was F. W. Bessel, who tried to reconcile the difficulty by an increase of the mass of Saturn, but found that he could do so only by assigning a mass not otherwise admissible. Although the idea that the deviations were probably due to the action of an ultra-Uranian planet was entertained by Bouvard, Bessel and doubtless others, it would seem that the first clear statement of a conviction that such was the case, and that it was advisable to reach some conclusion as to the position of the disturbing body, was expressed by the Rev. T. J. Hussey, an English amateur astronomer. In a letter to Sir George B. Airy in 1834 he inquired Airy's views of the subject, and offered to search for the planet with his own equatorial if the required estimate of its position could be supplied. Airy expressed himself as not fully satisfied that the deviation might not arise from errors in the perturbations. He therefore was not certain of any extraneous action; but even if there was, he doubted the possibility of determining the place of a planet which might produce it. In 1837 Bouvard, in conjunction with his nephew Eugène, was again working on the problem; but they appear not to have gone farther than to collect observations and to compare the results with Bouvard's tables.

In 1835 F. B. G. Nicolai, director of the observatory at Mannheim, in discussing the motion of Halley's comet, considered the possibility that it was acted upon by an ultra-Uranian planet, the existence of which was made probable by the disagreement between the older and more recent observations.

In 1838 Airy showed in a letter to the *Astronomische Nachrichten* that not only the heliocentric longitude, but the tabulated radius vector of Uranus was largely in error, but made no suggestions as to the cause. In 1843 the Royal Society of Sciences of Göttingen offered a prize of 50 ducats for a satisfactory working up of the whole theory of the motions of Uranus, assigning September 1846 as the time within which competing papers should be presented. It is also recorded that Bessel, during a visit to England in 1842, in a conversation with Sir John Herschel, expressed the conviction that Uranus was disturbed by an unknown planet. He went so far as to set his assistant Fleming at the work of reducing the observations, but died before more was done.

The question had now reached a stage when it needed only a vigorous effort by an able mathematician to solve the problem. Such a man was found in John Couch Adams, then a student of St. John's College, Cambridge, who seriously attacked the problem in 1843, the year in which he took his bachelor's degree. He soon found that the observations of Uranus could be fairly well represented by the action of a planet moving in a radius of twice the mean distance of Uranus, which would closely correspond to Bode's law. During the two following years he investigated the possible eccentricity of the orbit, and in September 1845 communicated his results to Professor James Challis. In 1845, about the 1st of November, Adams also sent his completed elements to Airy, stating that according to his calculations the observed irregularities in the motion of Uranus could be accounted for by the action of an exterior planet, of which the motions and orbital elements were given. It is worthy of note that the heliocentric longitude of the unknown body as derived from these elements is only between one and two degrees in error, while the planet was within half a degree of the ecliptic. Two or three evenings assiduously devoted to the search could not therefore have failed to

make the planet known. Adams's paper was accompanied by a comparison of his theory with the observations of Uranus from 1780, showing an excellent agreement. Airy in replying to this letter inquired whether the assumed perturbation would also explain the error of the radius-vector of Uranus, which he seemed to consider the crucial test of correctness.

The Elements.—At Arago's suggestion the investigation had been taken up by U. J. J. Leverrier, who had published some excellent work in theoretical astronomy. Leverrier's first published communication on the subject was made to the French Academy on the 10th of November 1845, a few days after Adams's results were in the hands of Airy and Challis. A second memoir was presented by Leverrier in 1846 (June 1). His investigation was more thorough than that of Adams. He first showed that the observations of Uranus could not be accounted for by the attraction of known bodies. Considering in succession various explanations, he found none admissible except that of a planet exterior to Uranus. Considering the distances to be double that of Uranus he then investigated the other elements of the orbit.

The following are the elements found by Adams and Leverrier:

	Leverrier	Adams	
		Hypothesis I	Hypothesis II
Semi-major axis . . .	36.154	38.38	37.27
Eccentricity . . .	0.1076	0.16103	0.12062
Long. of perihelion . . .	284° 45'	315° 57'	299° 11'
Mean longitude . . .	318° 47'	325° 8'	323° 2'
Epoch . . .	1847, Jan. 1	1846, Oct. 1	1846, Oct. 1
True longitude . . .	326° 32'	328°	329°

The longitude of the planet was 327° 57' on Oct. 1, 1846.

The close agreement of these elements led Airy to suggest to Challis, on the 9th of July 1846, a search for the planet with the Northumberland telescope. He proposed an examination of a part of the heavens 30° long in the direction of the ecliptic and 10° broad, and estimated the number of hours' work likely to be employed in this sweep. The proposed sweeps were commenced by Challis on the 29th of July. The plan required each region to be swept through twice, and the positions of all the known stars found to be compared, in order that the position of the planet might be detected by its motion. On the 31st of August Leverrier's concluding paper was presented to the French Academy, and on the 18th of September he wrote to John G. Galle (1812–1910), then chief assistant at the Berlin observatory, suggesting that he should search for the computed planet, with the hope of detecting it by its disk, which was probably more than 3" in diameter. This letter, probably received on the 23rd of September, was communicated to J. F. Encke, the director of the observatory, who approved of the search. H. L. d'Arrest, a student living at the observatory, expressed a wish to assist. In the evening the search was commenced, but it was not found possible to detect any planet by its disk. Star charts were at the time being prepared at the observatory under the auspices of the Berlin Academy of Sciences. It was suggested by d'Arrest that this region might be covered by one of the charts. Referring to the chart, which was lying in a drawer, it was found that such was the case. Comparing the stars on the chart one by one with the heavens it was found that an eighth magnitude star now visible was not on the chart. This object was observed until after midnight, but no certain motion was detected. On the following evening the object was again looked for, and found to have moved. The existence of the planet was thus established. It was afterwards found that Challis had observed the planet on Aug. 4, but had failed to detect it.

The question whether Leverrier should receive the sole credit of the discovery was warmly discussed. Arago took the extreme ground that actual publication alone should be considered, rejecting Adams's communications to Airy and Challis as quite unworthy of consideration. He also suggested that the name of Leverrier should be given to the planet, but this proposal was received with so little favour outside of France that he speedily withdrew it, proposing that of Neptune instead.

The observations at the first opposition showed that the planet was moving in a nearly circular orbit, and was at a mean distance from the sun much less than that set by Leverrier as the smallest possible. The latter had in fact committed the error of determining the limits by considering the variations of the elements one at a time, assuming in the case of each that while it varied the others remained constant. But a simultaneous variation of all the elements would have shown that the representation of the observations of Uranus would be improved by a simultaneous diminution of both the eccentricity and the mean distance, the orbit becoming more nearly circular and the planet being brought nearer to the sun. But this was not at first clearly seen, and Benjamin Peirce of Harvard University went so far as to maintain that there was a discontinuity between the solution of Adams and Leverrier and the solution offered by the planet itself, and that the coincidence in direction of the actual and computed planet was an accident. But this view was not well founded, and the only explanation needed was to be found in Leverrier's faulty method of determining the limits within which the planet must be situated. As a matter of fact the actual motion of the planet during the century preceding, as derived from Leverrier's elements, was much nearer the truth than the elements themselves were. This arose from the fact that his very elliptic orbit, by its large eccentricity, brought the planet near to the sun, and therefore near to its true position, during the period from 1780 to 1845, when the action on Uranus was at its greatest.

The observations of the first opposition enabled Sears Cook Walker of the National Observatory, Washington, in February 1847 to compute the past positions of the planet, and identify it with a star observed by Lalande at Paris in May 1795. This being communicated to the Paris observatory, an examination of Lalande's manuscript showed that he had made two observations of the planet, on the 8th and 10th of May and finding them discordant had rejected one as probably in error, and marked the other as questionable. A mere re-examination of the region to see which observation was in error would have led him to the discovery of the planet more than half a century before it was actually recognized. The identity of Lalande's star with Neptune was also independently shown by Petersen of Altona.

BIBLIOGRAPHY.—The principal sources for the history of the discovery of Neptune are the *Astronomische Nachrichten*, vols. xxv., xxvi., xxviii., and Lindenau's paper in the *Ergänzungsheft* to this publication, pp. 1–31 (Altona, 1849). In the *Memoirs of the Royal Astronomical Society*, vol. xvi., Airy gave a detailed history of the circumstances connected with the discovery, so far as he was cognizant of them. Documents pertaining to the subject are found in the *Monthly Notices of the Royal Astron. Society*. B. A. Gould, *Report to the Smithsonian Institution on the History of the Discovery of Neptune*, published by the Smithsonian Institution (Washington, 1850), is the most complete and detailed history of all the circumstances connected with the discovery, and with the early investigations on the orbit of the planet, that has been published. Leverrier's investigation was published in *extenso* as an addition to the *Connaissance des temps*, and Adams's as an appendix to the *Nautical Almanac* for 1851. Peirce's discussions, so far as published at all, are found in the *Proceedings of the American Academy of Arts and Sciences*. The first computations of the orbit after the discovery were made by Sears Cook Walker, and published by the Smithsonian Institution (1848–1850). General tables of the motion of Neptune are in Kowalski's *Tables du mouvement de la planète Neptune*; Newcomb's *Investigation of the Orbit of Neptune*, Washington, Smithsonian Institution (1866); Leverrier's *Annales de l'Observatoire de Paris; Memoirs*, vol. xiv. (1877), and lastly Newcomb's "Tables" in *Astron. Papers of the American Ephemeris*, vol. vii., part iv. Tables of the satellite are found in Newcomb, *The Uranian and Neptunian Systems*; appendix to the Washington observations for 1873.

(S. N.; T. E. R. P.)

NÉRAC, a town of France in the department of Lot-et-Garonne, 16 m. W.S.W. of Agen by road. Pop. (1926) 3,597. Nérac in the 11th century was a possession of the monks of St. Pierre de Condom. The lords of Albret deprived them of their authority and at the beginning of the 14th century founded a castle on the Baise. Nérac, the inhabitants of which had adopted the Reformed religion, was seized by the Catholics in 1562. The conferences, held there at the end of 1578 between the Catholics and Protestants, ended in the peace of Nérac, 1579. In 1580 the

town was used by Henry IV. as a base for attacks on the Agenais, Armagnac and Guienne. A *Chambre de l'Edit* for Guienne and a *Chambre des Comptes* were established there by Henry IV. In 1621, however, the town took part in the Protestant rising, was taken by the troops of Louis XIII. and its fortifications dismantled. Soon after it was deprived both of the *Chambre de l'Edit* and of the *Chambre des Comptes*, and its ruin was completed by the revocation of the Edict of Nantes in 1685. The town, once the capital of the dukes of Albret, is divided by the Baise into Grand-Nérac and Petit-Nérac. The river is spanned by the 16th century bridge of Pont Vieux, and by the Pont Neuf, of modern construction. From the left bank a staircase leads to the rue Henri Quatre, where stands a wing of the castle in which Henry IV. lived. The former palace of the *Chambre des Comptes* is now occupied by the tribunal of commerce, the library and the museum. The remains of a Roman villa have been found near the promenade of La Garenne. A road leads from the south end of La Garenne to the ruins of the feudal castle of Nazareth. The Château du Tasta of the 15th century is within a short distance of Nérac. The industries include brewing and cork-working. It has a large trade in wines, brandy, corks, fruit and vegetables.

NERBUDDA: see NARBADA.

NERCHINSK, a town of Asiatic Russia, in the Sretensk district of the Far Eastern area, in lat. $52^{\circ} 10' N.$, long. $116^{\circ} 32' E.$, on the left bank of the Nercha, $2\frac{1}{2}$ m. above its confluence with the Shilka. Pop. (1926) 6,545. It is a centre for the collection of furs, cattle and brick-tea from China and for the distribution of manufactured goods imported from industrial Russia. There are tanneries, candle factories and a fur coat factory. The town is a market for the agricultural products of the fertile river valley.

The fort dates from 1654, and the town was founded in 1658 by Pashkov, who in that year opened direct communication between the Russian settlements in Transbaikalia and those on the Amur which had been founded by Cossacks and fur-traders coming from the Yakutsk region. In 1689 was signed between Russia and China the Treaty of Nerchinsk, which stopped for two centuries the further advance of the Russians into the basin of the Amur. After that Nerchinsk became the chief centre for the trade with China. The opening of the western route through Mongolia, by Urga, and the establishment of a custom-house at Kiakhta in 1728 diverted this trade into a new channel. But Nerchinsk acquired fresh importance from the influx of immigrants into eastern Transbaikalia, the discovery of rich mines and the arrival of great numbers of convicts. In 1812 it was transferred from the banks of the Shilka to its present site.

NERCHINSK (in full NERCHINSKIY ZAVOD), a town and silver-mine of Asiatic Russia in the Sretensk district of the Far Eastern Area, in lat. $51^{\circ} 59' N.$, long. $116^{\circ} 39' E.$, 150 m. E.S.E. of another Nerchinsk (*q.v.*) (with which it is often confused), on a small affluent of the Argun. Pop. (1926) 3,153. It has a chemical laboratory for mining purposes, and a meteorological and magnetic observatory ($51^{\circ} 18' N.$, $119^{\circ} 37' E.$, 2,200 ft. above sea-level) founded in 1842. The average yearly temperature is $25.3^{\circ} F.$, with extremes of 97.7° and -52.6° .
